In "Men's Wives" Thackeray gives us a vivid description of Dennis Hagerty, the raw-boned young regimental surgeon who falls an easy victim to the charms of a third-rate boarding house belle. After the consummation of his marriage, nothing will do but that Dennis should resign his commission in the army and return to Ireland with his bride, to New Molloyville, where his old friend, the supposed narrator of the story, comes across him with a numerous progeny. In the meantime, his wife has become afflicted with smallpox and loses her vision, which has tended to make her shrewish temper all the worse. The picture of poor Dennis trying to be cheerful and welcome his guest to his cottage, is indeed a sad and pathetic one. Luckily for him, the virago suddenly leaves him, though Dennis feels the blow bitterly and is constant to the last.

As Dickens is known to have taken Smollett for his master, so Thackeray, to a great extent, took Fielding for his, but we have many touches in his works reminding us of Smollett also. Undoubtedly, Roderick Random suggested Dickens's David Copperfield, and there are reminders in Pendennis and other of Thackeray's works of many instances in "Ferdinand, Count Fathom," and other of Smollett's works. In short, as his great predecessors did, Thackeray used his wonderful powers of analysis of the manners and customs of men, particularly with a view to holding up the sham and the tinsel, and physicians received their share of criticism from his trenchant pen. But this was always tempered with charity and the severe ridicule of physicians, such as is noticeable in Smollett's "Humphry Clinker" and "Ferdinand, Count Fathom" is absent, or at least mitigated to such an extent that it leaves no bitterness. What more touching tribute to the profession can be imagined than Thackeray's lines in Pendennis: "It is not only for the sick man, it is for the sick man's friends that the doctor comes. His presence is often as good for them as for the patient, and they long for him yet more eagerly. How we have all watched for him! What an emotion the

thrill of his carriage wheels in the street and at length at the door has made us feel! How we hang upon his words and what comfort we get from a smile or two, if he can vouchsafe that sunshine to lighten our darkness! Who hasn't seen the mother prying into his face to know if there is any hope for the sick infant that cannot speak and that lies yonder with its little frame battling with fever? Ah, how she looks into his eyes! What thanks if there is light there,—what grief and pain if he cast them down and does not say 'hope.' Or it is the house father who is stricken. The terrified wife looks on while the physician feels his patient's wrist, smothering her agonies, as the children have been called upon to stay their plays and their talk. Over the patient in the fever, the wife expectant, the children unconscious, the Doctor stands as if he were Fate, the dispenser of life and death. He *must* let the patient off this time. The woman prays so for his respite. One can fancy how awful the responsibility must be to a conscientious man; how cruel the thought that he has given the wrong remedy, or that it might have been possible to do better! How harassing the sympathy with the survivors if the case is unfortunate—how immense the delight of victory!"

New Instrument.

A WATER-TIGHT URETERAL CATHETER TIP.

By FRANK H. LAHEY, M.D., BOSTON.

AFTER using the ureteral catheter tip as shown in the illustration below, I have given up the old perforated rubber nipples, as supplied by most of the dealers in cystoscopes, because it has been my experience that after a little use they allow of leakage, and even when new that with a strong contraction of the bladder there is often a leakage around them.

The tip as shown in this illustration is made by Eynard of Paris, and was intended not as a ureteral catheter connection for the cystoscope, but as a connection to be used between a syringe and ureteral catheter, so that injections might be made with a syringe not having a tip fine enough to enter the small opening in a ureteral catheter.

As is shown in the figure, it consists of a hollow rubber tube about 16 F. in size, the canal in one end, A, widening out for about one-third of its extent and more abruptly at its end B. The caliber of this tube, as supplied to me by Mr. Charles Bard, Eynard's American represen-

tative, is of sufficient size to fit snugly around a 4, 5 or 6 ureteral catheter. So snugly do they fit that it is impossible to introduce the catheter through it unless it is greased with a little sterile vaseline or some other oily lubricant. If this is done, even a No. 6 catheter may be introduced without difficulty.

The end A, with the longer taper to its canal, is slipped over the tunnel on the cystoscope, and in most cases it is best first to thread the tip onto the catheter for about one inch before slipping it over the catheter canal.

These connections are made of the very best rubber and remain water-tight for a long time.

Reports of Societies.

SECTION ON GENERAL MEDICINE OF THE COLLEGE OF PHYSICIANS OF PHILADELPHIA.

MEETING OF MONDAY, NOVEMBER 23, 1914, AT 8.15 P.M.

Dr. James E. Talley, in the Chair.

A CASE OF UNDETERMINED CONTINUED FEVER; ITS COURSE AND DESTINATION.

DR. B. F. STAHL AND DR. NORMAN B. GWYN: The case was that of a white woman aged 58 years, admitted to the wards complaining of pain in the lower left axilla. For many years she had been a steady drinker. She had been feeling poorly for about five weeks and occasionally feverish. There was a complete absence of physical signs except a few crepitations in the left axilla. No malarial parasites could be found. Wassermann reactions were negative; tuberculin, weakly positive; sputa repeatedly negative for T. B. The patient ate and slept well. A gradual wasting without pronounced anemia took place. At the end of five weeks there was distinct yellowing of the conjunctiva and enlarged veins coursing up over the thorax and down to the groins. Cirrhosis of the liver was definitely discussed in view of the history of alcoholism. The patient failed rapidly and three days later swelling of the abdomen began and pain in the right side of abdomen became marked. Four days later signs of fluid in the abdomen were distinct. The development of a tubercular peritonitis was considered probable, or of a mechanical peritonitis from a quickly disseminating new growth. At no time in the last ten days of life did it seem likely that operative measures would avail. The autopsy showed atrophic cirrhosis of liver deeply indented, suggesting a syphilitic process. Small area of T. B. in left upper lobe anteriorly placed. Interior of abdominal walls is studded with irregular, small nodules; mesentery studded with small irregular nodules with hemorrhagic tops. Serous coat of intestines has lost its gloss and a fine fibrinous layer is over all; in a good light minute tubercle-like formations are evident in abundance. Lower 8

c. m. of cecum is an immense ulcerating thickened mass. Other ulcerations in intestines evidently tubercular. Sections show condition is tubercular. Tubercle bacilli are found in macerated tubercles from peritoneum.

DISCUSSION.

DR. JOHN K. MITCHELL: I had under my care about four years ago a somewhat similar case in which the fever lasted for six months. Every night during that time, with one or two exceptions, the man had a temperature of from 102 to 103½. The only other symptom was a peculiar sweat. Tests of urine, feces and blood were negative. A number of consultants saw the man,—Dr. Lewis, Dr. Weir Mitchell, Dr. Thayer and Dr. Osler. None threw any light upon the case, except that Dr. Thayer ingeniously suggested psittacosis, tuberculosis in parrots. There were numbers of crystals of uric acid in the sweat, the odor of which was so bad that the man was obliged to get up in the night and take a bath. I sent him to the country and had him sleep out of doors. After two or three weeks the temperature came down and the man recovered in six or seven months without our having made a diagnosis. He is now perfectly well and weighs 190 pounds. The diagnosis is still in abeyance.

DR. ROBERT N. WILLSON: Last year at the Philadelphia Hospital there was a little Porto Rican girl who ran what seemed to us to be a low grade broncho-pneumonia. Then for two or three days she ran a normal temperature. Following that she would have rise of temperature again and then a return to normal. Headache was the only other symptom. This lasted for four months. There was always positive tuberculin reaction to tests, but we could not put our finger upon no focus. Finally the abdomen became greatly distended and we rashly called in the surgeon who operated and there was found in the centre of the abdomen a large caseous tubercular mass. This was removed with a tremendous loss of blood and the child died that night. Up to the day previous to the operation there was no suggestion of an abdominal condition, except a little tenderness over the appendiceal area.

DR. JOSEPH SAILER: I was interested in Dr. Gwyn's case because of the association of tuberculosis and cirrhosis of the liver. In my own experience I cannot say that in cirrhosis of the liver one case out of twelve had tuberculosis. In a case of prolonged fever under my observation some years ago there was also failure to reach a definite diagnosis. All tests were negative. The patient neither wasted nor gained and ran a temperature between 99 and 100, occasionally reaching 101. It was before the days of the Wassermann test. Upon the basis of the possibility of syphilis antisyphilitic remedies were used but without result. Another patient under my care had a temperature every day of 100. In six months' observations nothing very definite appeared. The woman gained about seven pounds upon prolonged rest cure, but did not lose her fever. Prolapse of the uterus was the only definite gynecological symptom. Dr. Clark operated in the hope of gaining more light on the case, when a fairly large solid ovarian tumor was removed. The patient lost her temperature and completely recovered her health.

DR. WILLIAM M. L. COPLIN: One point not accentuated is that in post-mortems we see an un-

usual type of tuberculosis in which caseation or other form of necrosis is slight or absent. The masses on the peritoneum in this case were elevated with hemorrhagic summits, often appearing almost papillomatous; the sand grain surface of miliary tuberculosis is absent. There were one or two ulcers in the intestine typically tuberculous. In many of these irregular forms of tuberculosis it is possible that we may find a tubercle bacillus of an unusual type. There is a fibrosclerotic change in the nodules which is very conspicuous. The appearance is almost that of complete healing with absence of caseation bringing forward the suggestion urged by French writers that there is a fibrogenic toxin produced by the tubercle bacillus differing from the caseogenous toxin commonly so characteristic of tuberculosis.

A CASE OF TYPHOID FEVER COMPLICATED BY ORCHITIS.

DR. S. H. ROSENTHAL: The case was admitted to the Philadelphia General Hospital, October 2, 1914. The patient who was 18 years of age passed through a mild attack of typhoid fever, the temperature became normal on the 13th day. Twelve days later the patient was seized with intense pain in the left lower portion of the abdomen. The temperature went up to 101; pulse rate was 120; leucocyte count 28,000. Distinct rigidity and tenderness were present in this area and the patient vomited twice. The following morning the pain shifted to the left testicle, the abdominal pain subsiding. The testicle and epididymis were found very much swollen and tender and the scrotum inflamed, with tenderness along vas and enlargement of left inguinal glands. The leucocyte count gradually came down to 9,000. Twenty days after the onset of this complication an incision was made in the left testicle and pus found. Typhoid bacilli were obtained in pure culture and were agglutinated by the patient's serum and the serum of another known typhoid case. Patient is still in the ward, the wound draining. There is no history of venereal infection. Orchitis and epididymitis are comparatively rare complications of typhoid fever, the percentage being about 0.2. Only a few more than 100 cases have been reported. Some arise from thrombosis of the spermatic veins; in a few the typhoid bacilli gain access to the epididymis and testicle by way of the vas from the urine, but in the majority of cases the source of infection is in the blood. The complication occurs most frequently between the ages of 15 and 25, appearing late in the disease or in convalescence, lasting from 12 to 18 days and terminating in resolution although induration and atrophy of the testicle or suppuration may occur. In the presence of suppuration there is apt to be extensive sloughing which practically destroys the entire testicle.

SOME OF THE UNUSUAL FEATURES OF TUBERCULOUS MENINGITIS.

DR. THOMAS McCRAE: The report deals with a case of tuberculous meningitis in which symptoms had existed for eight weeks before death. There was a marked variation in the symptoms, the patient's mental condition changing from day to day. The eye symptoms were also variable, paralysis being present one day and gone the next. Retraction of the head and Kernig's sign were not

particularly marked. Lumbar puncture gave a clear fluid with a cell count of 100. Tubercle bacilli were not found. At autopsy only a few tubercles were found on the cerebral meninges and there was little change in the meninges themselves. It seemed rather difficult at first to give an explanation of the symptoms when the autopsy findings were studied. The brain was hardened as a whole and when sectioned three caseous areas were found in the occipital lobes. These contained large numbers of tubercle bacilli. In this case many of the symptoms were apparently due to general toxemia and not to the local tuberculous process in the meninges. The variation in the eye signs seemed most probably to be from edema. The lungs showed a large number of very young miliary tubercles, evidently much younger than those in the meninges. The source of infection was apparently a tuberculous epididymitis.

DISCUSSION.

DR. WILLIAM M. L. COPLIN: The lesions in the gray and white matter of the brain of this case were old with distinct caseation. It is possible that the extension of infection may have occurred from them to the meninges rather than by hematogenous dissemination to the meninges, lungs and other organs. I am reminded of one case in which there was perfectly clear evidence of at least two eruptions of miliary tuberculosis. These were seen in the liver in the presence of definitely healed tubercles, and perfectly fresh granulations with absolutely no evidence of any reparative effort.

DR. JOSEPH SAILER: I recall the report of a case of tubercular meningitis in which after one or two years the patient died of some other condition and in which healed tubercular lesions were found in the meninges.

DR. B. F. STAHL: In a case reported by a colleague some time ago the patient had tubercle bacilli in the spinal fluid, had all the symptoms of meningitis and in addition had tuberculosis of the lungs; and, if I remember the case clearly, he had a cavity. The patient made a surprising recovery from his tubercular meningitis. He was at White Haven for four or six months. I saw the patient four years after he returned to Philadelphia. The development of the disease was entirely arrested and the man is now a timekeeper for one of our contractors.

DR. DAVID RIESMAN: There came under my observation some time ago a woman, stout and healthy looking, whose condition presented continuous fever with intense headache. There was history of two separate attacks of typhoid fever. There was no positive Kernig's sign, but some rigidity of the neck. Lumbar puncture showed the spinal fluid to be almost typical of tuberculosis. Complete recovery took place. The presence of small tuberculous lesions, it seems to me, is very important in the diagnosis of an obscure case which might be tubercular meningitis. I recall the cases of two middle aged women who seemed to have typhoid fever. In the examination of one a little lump was discovered in the back, probably the result of an old Pott's disease. Subsequently all the symptoms of miliary tuberculosis developed and the patient died of that disease. In the second patient the picture was definitely that of typhoid fever. She had also a little enlargement in the back. This together with the headache suggested tubercular

meningitis which the condition was subsequently proved to be. I feel, therefore, that these small lesions, in the intestines, epididymis and in the joints are not infrequently the cause of a miliary tuberculosis or tuberculous meningitis. I would particularly point out that these little remnants of an old and forgotten Pott's disease are very interesting in diagnosis.

DR. ROBERT L. PITFIELD: In a case of meningitis seen in my service to-day lumbar puncture showed tubercle bacilli, diplococci and pneumococci. The edema of the face, choked disc and the fact that the complete coma was not relieved by lumbar puncture led me to think that possibly the cause of the comatose condition was a blocking up of the foramen of Monro and the overflow of fluid into the left ventricle. It occurs to me that this case of Dr. McCrae might be due to an accumulation of fluid as well as to the toxic condition mentioned.

DR. A. P. FRANCINE: I have seen three cases which developed many of the typical features of meningitis which remained for a definite period, and in which the diagnosis was made of tuberculous meningitis in the course of advanced pulmonary tuberculosis. All three cases cleared up without evidence of tuberculous involvement of the meninges or brain. I, therefore, look upon these cases as possibly of nephritic origin or due to toxemia. I am rather skeptical of a tuberculous meningitis that recovers. I have seen such so-called cases recover, but there has been a complete absence of tubercular meningitis.

DR. ALFRED STENGEL: One of two cases occurring to me is that of a woman who has just left University Hospital having been brought in with marked cerebral symptoms and developing soon after a paralysis of her external rectus muscle in one eye with marked diplopia. There was retinitis with swelling of the nerve head four diopters. There were somnolence and various other nervous disturbances not terminating in coma. The condition had begun with apparently acute infection which we eventually discovered to be tuberculous. She remained in the hospital for three or four weeks. While tuberculous meningitis was not demonstrated, its suggestion was very strong and it might possibly have been a case of healed tuberculous meningitis. Dr. deSchweinitz who saw the case with me, recalled to my mind a case we had seen together some years ago in which there were all the symptoms of tuberculous meningitis in a young boy in whom he had found tubercles in the retina. There was complete recovery from the meningeal and retinal conditions. These two cases suggest to me the possibilities of healed tuberculous lesions on the meninges.

THE ABDERHALDEN TEST WITH ITS RELATION TO DISEASE OF THE LIVER.

DR. JOSEPH SAILER AND DR. T. G. SCHNABEL: Breitmenn, having reported the successful application of the Abderhalden test in diagnosing destructive disease of the liver, an effort was made to confirm or disprove his statement. In all 43 cases that were examined the dialyzing method was used. In each case the serum and the substratum were tested separately and if free from dialyzable substances and negative with the ninhydrin test, they were tested together. If, after this a positive ninhydrin test was obtained, the result was considered as posi-

tive. Tests were also made whenever a sufficient amount of serum could be obtained with kidney, thyroid and placenta substratum, and when possible, several tests were made with the liver substratum. It was not possible in all cases to verify the diagnosis by autopsy or operation, but as far as possible, only very definite clinical cases of liver disease were included under that head. The following results were obtained:

Five cases of secondary malignant disease of the liver, all strongly positive.

Two cases of cholelithiasis; one strongly positive, and one faintly positive.

One case of cholecystitis with adhesions and jaundice, moderately positive.

Five cases of atrophic cirrhosis; all probably alcoholic; two were moderately positive; two, very strongly positive and one negative.

Four cases of passive congestion of the liver secondary to cardiorenal disease, all strongly positive.

Two cases put down as enlarged liver, positive.

One case put down as suspected liver disease without definite symptoms, faintly positive.

Three cases of syphilitic cirrhosis with positive Wassermann's, all positive. One of these was positive after the injection of salvarsan.

Two cases of hypertrophic cirrhosis, both positive.

The control with serum of a supposedly normal person gave a very faintly positive reaction with both liver and kidney substratum.

One case of renal insufficiency one week after induced abortion gave a strong reaction with liver, strong reaction with thyroid and intensely strong reaction with placenta.

Another case of supposed puerperal infection gave a strong reaction with placenta, but none with either liver or thyroid.

In a case of suspected pregnancy, afterwards proven not to be, there was no reaction with either tissue.

In two cases of lobar pneumonia the serum of both showed dialyzable substances and gave a positive reaction with ninhydrin.

In one case of myxedema a very faint reaction was obtained with liver substratum but with no others.

In one case of known pregnancy there was no reaction with liver tissue, faint reaction with thyroid, and strong reaction with placenta.

In a case of malaria there was a strong reaction with liver tissue, with kidney tissue, and with thyroid tissue.

Case of multiple serositis there was a faint reaction with liver, thyroid and placenta.

In a case of recurrent alopecia, which had been diagnosed by two other physicians as disturbance of the thyroid gland, there was no reaction with any substratum.

On the whole the results indicated that the reaction was positive in the majority of known cases of liver disease and occasionally positive in cases not known or supposed to have liver disease, and in which the complete demonstration of a normal liver naturally could not be made.

DISCUSSION.

DR. PHILIP L. WILLIAMS: We have used the Abderhalden test at the University Maternity for the last few years. From our experience and from the various reports upon the test it would seem that the underlying principle had not been fully worked

out. For that reason, when one takes up such diverse pathological conditions as are seen in disease of the liver, great caution should be used in reading the results obtained.

DR. DAVID RIESMAN: Results obtained by Drs. Sailer, Schnabel and Williams show that as a biological fact the Abderhalden theory is indisputable. In its clinical application, however, confusion has apparently been wrought by a number of writers who have obtained contradictory results and discredited the theory.

DR. SAILER, closing: Our work was partly undertaken as the result of Breitmänn's investigations. Whether subsequent results will be equally satisfactory it is impossible to tell. It is clear, I think to all clinicians, that diagnosis of liver conditions is in the most unsatisfactory state aside from certain well marked clinical conditions easily recognized. I think it can be said of the very considerable amount of work involved that we have set the subject rather fully before the medical profession, and that the results suggest that under certain conditions the Abderhalden test may in the future have an established value in certain morbid conditions of the liver.

THE DIAGNOSIS BETWEEN PRIMARY AND SECONDARY ACUTE CARDIAC PICTURES.

DR. ROBERT N. WILLSON: It is with a full appreciation of the intimacy of the confidence imposed upon the consultant and of the restrictions limiting the ownership of clinical data acquired in such relation that I venture to sketch briefly four cases seen in conference with medical friends, the study of which and of similar cases has led me to attempt to formulate a working scheme for the discrimination between primary and secondary acute cardiac clinical syndromes. The paper discusses briefly such acute cardiac pictures as appear in neurotic states, in gastrointestinal toxemias, in the pneumonias, in tuberculosis, in hyperthyroidism, in drug intoxications and other systemic embarrassments tending to obscure the real causal factor and to over emphasize the heart. The question asked me in clinic "How does it happen so often that the first signs of a pulmonary tuberculosis are heart or stomach symptoms" graphically defines the aim and the limitations of this study. There are two general conditions in which discrimination is difficult, and two cardinal principles upon which it appears to me rational to base our procedures. The first of the general conditions is exemplified in a patient experiencing cardiac symptoms in the presence of, though not necessarily due to, organic muscular or valvular disease of the heart. The second may be noted in one suffering from a cardiac syndrome in the entire absence of a recognized antecedent lesion, and perhaps in the presence of a heart normal heretofore, and still normal under ordinary circumstances. The first and best method I could suggest would be a deliberate and complete ignoring of the heart in the preliminary, physical examination, and a studied effort to explain doubtful symptoms on other grounds than those of cardiac disease. Failing in this, and forced at length to consider the heart as the *origo et fons mali*, I would propose as the second essential in the diagnosis a still further reluctance to attribute more of importance to the cardiac disease than is its due, and a continual remembrance of the intimacy of the interrelation between the heart and every other of the thoracic and abdominal viscera, also the brain, and the influence

of this interrelation upon the symptoms arising from these organs. The lungs expand from the apex downward and carry the heart downward and the consequent interference with the veno-auricular flow is a far more vital menace than any mere mechanical obstruction in the pulmonary tissue. The bacteremias and toxemias, however, and not the consolidations and congestions are the vital factors threatening the heart. Because of this fact both the myocardium and the gastric mucosa offer their early complaint in tuberculosis and pneumonia, and for the same reason, not infrequently, the cardiac or the gastrointestinal picture dominates the course of the pulmonary disease. Our first step, therefore, is directed toward the exclusion of primary pulmonary disease. Next in the order of important causes of secondary cardiac disabilities is the effect of gastrointestinal toxins. A mechanical factor in the form of tympanitis may further embarrass the involved heart. Not infrequently acute renal or pulmonary conditions are contributory factors. The thyroid and pituitary disorders, the adrenal affections, the grave anemias, acute infectious diseases are to be considered. The point to be emphasized is, that a heart free from antecedent disease, may protest so vigorously concerning its vicarious distress that attention is diverted from the true etiology and treatment invited unavailing and detrimental. The second method of discrimination between the two pictures is the weighing of the influence of a known organic cardiac disease against the symptoms due to incompetency of other organs. All insufficiencies of the lungs, liver, kidneys, or gastrointestinal tract directly dependent upon cardiac disease, are properly a part of the primary cardiac picture.

There must be, however, sharp differentiation between symptoms attributable to an old valvular lesion with its accompanying myocardial degeneration, and lesions of intercurrent infectious pneumonia; between the syndromes of rheumatic endocarditis and myocarditis and the cardiac symptoms of an intercurrent gonorrhea, and distribution of the responsibility of symptoms in the coincidence of persistent influenzal pneumonitis or apical tuberculosis, and "rheumatic" or syphilitic organic cardiac disease. Careful history taking is an absolute essential. Study of the blood pressure, especially with respect to excessive pulse pressure or a cardiac overload, will often avoid the misinterpretation of an organic myocardial disease. We must by every rational endeavor avoid laying upon the heart an etiologic overload in the form of secondary symptoms.

Book Reviews.

Dissection Methods and Guides. By DAVID GREGG METHENY, M.D., L.R.C.P., L.R.C.S. (Edin.), L.F.P.S. (Glas.). Philadelphia and London: W. B. Saunders Company. 1914.

This monograph by a Scottish anatomist is a manual of method and technic in dissection, intended to bridge the gap between the descriptive textbook and the laboratory. It aims to teach the student how to dissect, not what he is to discover by dissection. The work is illustrated with 12 plates representing lines of incision. It is a useful contribution to the pedagogic literature of anatomy.

THE LABOR CLEAN MILK BILL.

THE Legislative Committee of the State Branch of the American Federation of Labor has introduced at the present session of the Massachusetts Legislature a clean milk bill (Senate No. 78), which is very simple and direct. Expressed in a few words, it seems to cover the most important defect in our milk health laws. The provision that no person shall be prosecuted until he has first had a warning notice, makes it absolutely fair to the handlers of milk and ought to make it satisfactory to them. The bill covers milk produced or handled out of the state to be sold in this state, which after all should be the main object of our protective legislation, both from the point of view of the public health and from that of fair competition for Massachusetts producers.

The Federation has also recommended an appropriation to make the law effective, which we understand will call for \$35,000 "for the inspection of out-of-state dairies whose milk is sold in Massachusetts." This will enable the State De-

partment of Health to maintain ten inspectors on the out-of-state dairies. The plan is to give up the out-of-state inspection by the six dairy inspectors of the City of Boston and have the Commonwealth do this work for all the cities and towns of the state. At present this work is incompletely done, and with few exceptions the only out-of-state inspection is that of the City of Boston. It is not fair financially for Boston to pay for inspection which accrues to the benefit of many other places. Under the new bill the out-of-state inspection will be more complete and will remove the injustice to Boston. In any event, Boston will pay one-third of the cost, as it does in all state expenditures.

The state-wide jurisdiction of the State Department of Health will give it a very great advantage over local boards so far as out-of-state work is concerned.

We recommend that all the various organizations which have been active in support of milk legislation during the last few years should this year give up their own particular bills and support the Labor Clean Milk Bill, in the interest of an early solution of the milk problem. The text of the bill is as follows:—

Section 1. Whoever, himself, or by his agent, shall sell or have in his possession with intent to sell or deliver to any person for purposes of sale within the state, milk, skimmed milk or cream produced or handled inside or outside of the state in insanitary, unclean or unhealthful surroundings, or by insanitary, unclean or unhealthful methods, shall be punished by a fine of not more than three hundred dollars or by imprisonment for not more than thirty days, or by both such fine and imprisonment in the discretion of the court. No person shall be liable to prosecution under this act unless he has first received a warning notice from the state department of health prohibiting him from selling such milk, skimmed milk or cream. The District, Municipal and Police Courts shall have jurisdiction in equity upon the application of the State Department of Health or of a local board of health to enjoin the sale of such milk, skimmed milk or cream."

This bill is a substitute for the more elaborate and comprehensive Ellis Milk Bill which has for several years past been defeated before the legislature and which has been given up by its proponents after consultation with the labor interests. The bill as it stands is endorsed by many local country boards of health. Essentially the same measure without the modifying clauses about notification and jurisdiction in equity is already a law in thirty-five states of the Union,

including the largest. Communications from several of these states show that there has been no difficulty in enforcing the law. A letter from the chief of the division of creameries and dairies in one such state says in part:—

“In the several instances in which it has been necessary to prosecute dairymen for ‘insanitary, unclean or unhealthy methods,’ we have never failed to win a case, except where a jury composed of the friends of defendant rendered a verdict through sympathy. This happened in one or two instances several years ago and the cases were not appealed. Consequently, we have no ruling of the higher courts on these cases. During the past eight years, the few cases which we have brought have been decided in favor of the state on the testimony given by experts in this department. It usually happens that the courts here are in entire sympathy with our procedures, and they have frequently instructed juries to find verdicts in our favor.

“The use of the score card in our dairy inspections aids us very much, as each item of the dairy management is recorded and the inspector is enabled to explain to the court his reasons for allowing a small score on any item contained on the card.”

Though perhaps not ideal, the Labor Clean Milk Bill seems an adequate and desirable measure, and physicians who approve it are urged to write to their senators and representatives in its behalf.

LOCAL CARE OF ADVANCED TUBERCULOSIS.

By the legislative act of 1911 it was required that each town in this Commonwealth of 10,000 inhabitants, or over, must make local provision, either by the building of a dispensary or by arrangement with adjacent towns, for the care of tuberculates among its population. Certain towns and many of the larger cities had already made such provision and others within a short time complied with the requirements of the act. There still remained, however, a number of communities coming within the provisions of this law which have made no such provision or arrangement.

In 1914 an amendment to this law was passed, giving the state health authorities power to establish a standard for such tuberculosis dispensaries, and at that time the following requirements were outlined for these institutions:—

“The tuberculosis dispensaries shall be open in

the daytime during four days in the week, and during one evening in the week, this latter provision to take care of men who have to be at their work during the whole day. There shall be a physician competent to diagnose and to treat both incipient and more advanced cases of tuberculosis. There shall be a nurse, whose duty will be to serve the local cases; and eventually, if not in all cases at first, a social worker, whose business it will be to keep in touch with patients discharged from state sanatoria either cured or with the disease arrested.”

Four years have now passed since the enactment of the original legislation but there still remain eighteen of the thirty-five cities in Massachusetts without tuberculosis hospitals of their own. Most of these cities send some of their patients to other neighboring cities. Of the eighteen cities without tuberculosis hospitals, five have taken no action whatever towards complying with the action, two have merely appointed a committee which has taken no action. In the remainder, apparent intention to comply with the requirement has progressed to varying stages of incomplete accomplishment. These eighteen cities without tuberculosis hospitals are Attleboro, Beverly, Brockton, Chelsea, Everett, Gloucester, Lowell, Malden, Marlboro, Medford, Melrose, Newburyport, Newton, North Adams, Quincy, Revere, Taunton and Woburn. Seventeen large towns are similarly unprovided for. Seventeen of the thirty-five cities in the state either have their own hospital or have made arrangement with a private local hospital. These seventeen cities having suitable tuberculosis facilities are Boston, Cambridge, Chicopee, Fall River, Fitchburg, Haverhill, Holyoke, Lawrence, Lynn, New Bedford, Pittsfield, Salem, Somerville, Springfield, Waltham, Westfield and Worcester. There is one county hospital in Hampshire and a bill (Senate No. 10) is at present pending before the General Court to provide permission for the establishment of a similar hospital in Barnstable County.

It is obvious that there is still a considerable part of the population of this Commonwealth unprovided with proper local accommodation for patients with tuberculosis, and it is urgently desirable that this deficiency should be made good as speedily as may be. Three methods are available by which any community may comply with the provisions of the act. Any city may build and maintain a hospital of its own; or it may arrange by contract with a private hospital for beds and care sufficient to accommodate its indigent advanced cases; or it may combine with

neighboring communities in maintaining a joint hospital sufficient for the care of tuberculates within those communities. It was the original intention of this act to provide thus for the local care of advanced cases, the incipient and curable cases to be taken for more expert sanatorium treatment at the state hospitals. The problem of caring adequately for tuberculosis, of affording the opportunity of cure for those in the early stages, and of protecting the public against advanced cases, which are the principal disseminators of the infection, is one of the most important and one of the largest problems of public health which confronts civilization at the present day. Its solution cannot be expected until every community does its local part in such a well-laid and carefully detailed plan for action.

ANTI-VIVISECTION LEGISLATION.

THE usual annual legislative anti-vivisection agitation is at present being made in behalf of a bill now pending before the Massachusetts General Court forbidding the performance of any animal experiment on dogs. The text of this bill is as follows:—

“Section 1. It shall be unlawful to perform any physical or psychological experiment of a nature causing or likely to cause suffering, pain or disease to any living dog, for any purpose whatsoever, whether with or without anesthetics. This act, however, is not to be construed as interfering in any way with ordinary medical or surgical measures designed to restore to health or relieve from pain the animal under treatment.

“Section 2. Any person performing or assisting or taking part in performing any such experiment on any dog, in violation of this act, shall be punished for the first offence by a fine of not less than \$50 nor more than \$200, and for the second offence shall be punished by imprisonment for not more than one year, or by a fine of not less than \$200, or by both fine and imprisonment.”

A large petition has already been circulated in behalf of this bill, which was presented at a hearing before the committee on legal affairs on February 18.

At this hearing a number of advocates of the measure advanced the usual anti-vivisection arguments, with others based on the present European War, which they attributed to the brutalization of some of the contestants by the

practice of vivisection. Dr. W. B. Cannon, Dr. Theobald Smith, Dr. Langdon Frothingham, Dr. Reid Hunt, Dr. Elliott P. Joslin, Dr. David L. Edsall and Dr. Harvey Cushing appeared as opponents of the measure. Dr. Frothingham pointed out that the bill as it stands would prevent veterinarians from experimenting upon dogs, and Dr. Cushing emphasized the misinterpretation habitually placed by anti-vivisectionists upon the technical reports of animal experiments. Further consideration of the question was deferred to a later meeting of the committee.

It is hardly necessary to call attention to the undesirability of such legislation, which, like all measures of its kind, is inspired by the most humane though mistaken motives and in reality will prevent no avoidable suffering and would seriously hamper legitimate animal experimentation.

IMMIGRATION OF THE INSANE AND MENTALLY DEFECTIVE.

IN another column of this issue of the JOURNAL we publish in full a copy of the statement presented before a hearing given on January 22 on the immigration bill (House 6060), then pending before the National Congress. This statement relative to proposed amendments in this bill, relating to the exclusion and deportation of insane and mentally defective immigrants, was made on behalf of a delegation representing numerous state boards of insanity, the National Committee for Mental Hygiene, and other national and local organizations for psychiatry and mental hygiene. This delegation made clear that its appearance was not in behalf of the illiteracy test, but to point out the importance of provisions relating to the exclusion of insane and mentally defective. The members of the delegation represented that the amendments which they suggested should be included in the bill as measures dealing with administrative matters of public health. Whatever individual opinion may be upon the subject of immigration, it seems clear that the importance of controlling the increase in the number of our alien insane and defective by some such measures as those advocated in this statement should be made the subject of further earnest legislative efforts by the medical profession.

LOCATION OF METALLIC SUBSTANCES IN THE TISSUES.

FOREIGN medical journals have recently contained numerous publications of new radiographic and other methods for locating metallic foreign bodies in the tissues. In another column of this issue of the JOURNAL we publish a leading original article by Dr. Monks presenting a preliminary report of his new and ingenious method of employing magnetism for this purpose. Personal demonstration of this method carries conviction of its feasibility and practical value and we take pleasure in calling the attention of the profession to this new and valuable device of surgical technic.

MEDICAL NOTES

NEW YORK DEATH RATES.—The most noteworthy feature of the mortality during the past week was the great increase in the number of deaths of infants under one year of age, there being 262 deaths recorded at this age group, the increase being confined to the boroughs of Manhattan and The Bronx, and being probably due to an increased mortality among infants from pneumonia and diarrheal diseases. At all ages above five years the mortality was considerably below that of the corresponding week in 1914. There were seven less deaths reported during the past week than in the corresponding week of 1914, and a lower death rate by .62 of a point, which, taking into consideration the increase in population, is equivalent to a decrease of 69 deaths during the week.

Seven weeks have now elapsed since the first of January, 1915, and the death rate for that period is 13.92 per 1000 of the population, which is .67 of a point less than the rate in the corresponding period of the year 1914.

RECEPTION TO GENERAL GORGAS.—Surgeon General Gorgas, of the United States Army, was tendered a reception and banquet at the Hotel McAlpin, New York, on the evening of February 6th, by the New York Division of the Federal Reserve Corps. In addition to the members of the Association, a large number of regular medical officers were present, including Colonels Maus, Richard, Brechemin, and Bradley. Dr. Reynold Webb Wilcox, president of the Association, was toastmaster, and the speakers, other than the guest of the evening, were Colonels Maus and Richard, Drs. John A. Vyeth, George H. Fox, and W. M. Brickner. General Gorgas, in the course of his remarks, stated that the Army has supplies at present to take care of 400,000 men in the field.

CHICAGO TUBERCULOSIS SANATORIUM.—On February 16, the new Chicago Municipal Tuberculosis Sanatorium was formally dedicated with appropriate exercises. It already provides accommodation for 650 patients and will eventually accommodate 950. The buildings have been erected at a cost of \$2,400,000.

BUBONIC PLAGUE IN HAVANA.—Reports from Havana on Feb. 13 and 17 state that three cases of bubonic plague have recently been discovered in that city, all of which have already died. All wharves and houses near the water front have been disinfected and rigorous search for infected rats has been instituted.

EPIZOÖTIC OF FOOT AND MOUTH DISEASE.—Report from Peoria, Ill., on February 10 states that thirty-five new cases of foot and mouth disease have recently been discovered in Peoria County. The infected cattle have been killed and the quarantine of this county has been restored.

On February 2, the Kansas Legislature voted an emergency appropriation of \$20,000 to carry on a campaign against foot and mouth disease in the four counties of that state which are still under federal quarantine.

On February 15, the East Buffalo stockyards were again placed under complete quarantine. On the same date the United States Department of Agriculture extended the quarantine area so as to include all the territory east of the Mississippi and north of Tennessee in a restricted area out of which no shipments of livestock to the south or west will be permitted, except for slaughter within 48 hours. The Department issued the following statement explanatory of this action:—

“The recent discovery of a few cases where cattle, shipped from areas where the disease had existed, carried it to previously uninfected sections, such as four counties in Kansas, convinced the Department that no precautions will make such shipments absolutely safe. The new measure, it is said, should confine the disease to regions in which it has already made its appearance and in which the work of eradicating it will be pushed as before.

“In this restricted territory, livestock may be moved freely to other points within the same territory, but cannot pass beyond the limits of the quarantined area, except for immediate slaughter. The regulations governing the area known respectively as closed, exposed and modified, remain practically the same as before.”

RIBERI PRIZE.—It is announced by the Royal Academy of Medicine at Turin, Italy, that the thirteenth Riberi prize of the value of \$4,000 is offered for the best work of medical research presented before December 31, 1916. Further information may be obtained from Dr. V. Oliva, secretary of the Academy.

INFANT MORTALITY IN AN ENGLISH CITY.—A recently published annual report of the public health officer of Huddersfield, England, records the data of infant mortality in that town for 1913. Huddersfield is a typical manufacturing city with a population of about 111,000, increasing at a rate of about 1% per annum. The density of population is about ten to the acre. The mortality rate from all causes in 1913 was 14.77, which was .71 below the average for the preceding decade. The marriage rate was only 8.35 per thousand and the birth rate only 19.5, a decrease of one-half since 1872 and one-quarter since 1902. In the same year the death rate of Boston was 16.1 and the birth rate 26.17. The infant mortality of Huddersfield in 1913 was 103 per thousand, the average for the 96 largest cities of England and Wales being 117. The most frequent causes of infant death in Huddersfield are prematurity and bronchitis, whereas in Boston diarrheal disease and prematurity rank foremost.

PREVALENCE OF MENINGITIS AND POLIOMYELITIS.—During the month of December, 1914, 39 cases of cerebrospinal meningitis and 7 of poliomyelitis were reported in New York State. During the same month 10 cases of poliomyelitis occurred in Mississippi.

EUROPEAN WAR NOTES.—Report from Venice by way of London on February 13, states that during the first week of February there were 423 cases of typhus fever in Austria and that small-pox is spreading in epidemic form in Vienna.

Report from Washington on February 9 states that the Russian Government has refused to permit an American expedition from Peking, China, to engage in relief work among the German and Austrian prisoners in Siberia. It has, therefore, been decided that a portion of the American supplies furnished by the American Red Cross shall be turned over to Russian military authorities for use in prison camps. Two American physicians have volunteered to go to Siberia with these supplies if the Russian Government grants permission.

Report from Washington on February 12 states that the French foreign office has requested that one of the American Red Cross Units at Pau be transferred to Dunkirk or some other point in the northeast. In view of the number of serious cases now under care at Pau, however, it has been decided by the American Red Cross to authorize the offer of another hospital unit for service in France at Dunkirk or elsewhere, the unit at Pau being retained at its present post.

The weekly bulletin of the United States Public Health Service for February 5 records great activity in plague prevention at Liverpool, England, where much apprehension is felt of the introduction of the plague during the war. Dur-

ing the fortnight ended January 2, 234 rats were killed and examined at Liverpool but none was found to be infected. When certain precautions have been consistently carried out by vessels from the moment of arrival until that of departure, a certificate as to the precautions taken to guard against the introduction of rats on the vessel during its stay at Liverpool is issued.

"The first step taken is to secure a notification of the arrival of a vessel which is, so to speak, a candidate for such a certificate, prior to its reaching the dock. If such a warning is not given which will allow an inspection immediately on the arrival of the vessel no certificate can be obtained, as notifications after the arrival of a ship are not acted upon. All of the regular steamship lines understand this, and no difficulty is experienced in receiving notification in due time to admit of the inspector ascertaining by his own visit to the dock what precautions are instituted. The requirements are: That a vessel be kept at least six feet away from the quay at all times; that rat guards be placed on all lines connected with the ship, and that the said guards shall be of an adequate character; that all lighters alongside the vessel shall be a sufficient distance from the upper part of the ship's first deck to render it impossible for a rat to transverse the intervening space, and that all ropes connecting said lighters shall be properly guarded, or shall be light lines so small as to make their use by a rat impossible.

The inspector visits each ship in port which is held under observation on an average once each day, and at irregular hours, and a record of each visit, with a note as to his findings, is made in a permanent record book.

Just prior to the proposed sailing of a vessel the owners or responsible agents submit a statement in writing as to the steps that have been taken to guard against the entry of rats to the ship. If this statement agrees with the daily record of the inspector it is indorsed by the consular officer issuing the bill of health showing that it is correct, and the same is attached to the bill of health. Indorsement is also made on the bill of health."

On February 19 the total of the New York Belgian Relief Fund amounted to \$932,684.28; the New York Red Cross Fund to \$460,060.47; the American Jewish Relief Fund to \$482,952.13; the American Ambulance Hospital Fund to \$326,870.86; the Committee of Mercy Fund to \$118,804.92; and the Prince of Wales Fund to \$109,893.49.

On February 20 the total of the New England Belgian Relief Fund amounted to \$217,923.93; Massachusetts Red Cross Fund to \$110,098.12; the American Polish Relief Fund to \$22,874.97; the Jewish Relief Fund to \$36,508.21; the British Relief Fund to \$19,916.84; the Lithuanian Relief Fund to \$10,333.49; and the Boston Branch of the American Ambulance Fund to \$54,006.45.

BOSTON AND NEW ENGLAND.

ANGELL MEMORIAL ANIMAL HOSPITAL.—It is announced that the formal dedication of the new Angell Memorial Animal Hospital, of which full description was published in the issue of the JOURNAL for January 21, will take place on Thursday afternoon, February 25, between two and five o'clock.

MASSACHUSETTS SCHOOLMASTERS' CLUB.—At a meeting of the Massachusetts Schoolmasters' Club in Boston on February 12, Dr. Richard C. Abot of this city spoke on the subject of "Health from the School Standpoint," and urged the establishment of school clinics for the education of pupils in practical hygiene. Dr. Thomas F. Harrington, director of the department of hygiene of the Boston public schools, presented a series of results from statistical examinations of Boston school-children and urged that the matter of health in the schools should be regarded as an educational problem. Dr. David Snedden of the Massachusetts state board of education and Dr. Thomas A. Storey, director of the department of hygiene of the College of the City of New York, also spoke in favor of public school health education.

MASSACHUSETTS VITAL STATISTICS IN 1914.—A recent report of the Massachusetts Secretary of State records in preliminary form the vital statistics of this Commonwealth for the year 1914. "The report shows that there were 31,403 marriages and 91,644 births in the state last year, an increase of 505 marriages and 1,762 births over 1913. "Last year 59,564 persons died in Massachusetts, a decrease of 1,122 as compared with 1913. The births in 1913 thus exceeded the deaths by more than 32,000."

FOOT AND MOUTH DISEASE IN NEW ENGLAND.—Simultaneously with the recurrence of foot and mouth disease in several of the Western States, previously noted in this issue of the JOURNAL, there has been a recrudescence of the epizootic of this infection in Massachusetts and other New England States. The outbreak of last fall involved 32 cities and towns and nearly 1,200 cattle of this commonwealth. The present outbreak, which has been in progress since February 1, already involves eight cities and towns and 249 cattle, of which 181 have already been slaughtered. Of the cases thus far reported there have been 10 in Chicopee, 25 in New Braintree, 1 in Oakham, 19 in Southboro, two in Springfield, 82 in Waltham, 22 in Watertown and 65 in Worcester. In Rhode Island new cases have been discovered at Smithfield and Pawtucket. It has not been determined how the infection has been reintroduced into the New England States, but its discovery has been prompt, the machinery for dealing with it ready and the rigorous methods of quarantine and slaughter instituted,

should bring this epizootic to a much speedier end than its predecessor with a minimum destruction of property.

Miscellany.

AMENDMENTS IN THE IMMIGRATION BILL (H. R. 6060) WHICH RELATE TO EXCLUSION AND DEPORTATION OF INSANE AND MENTALLY DEFECTIVE IMMIGRANTS*

THE gentlemen for whom I have the honor to be the spokesman desire to bring to your attention certain provisions in the immigration bill which relate to insane or mentally defective aliens and to state very briefly the reasons for these amendments to the present immigration law. There are no other provisions in this bill which, in our opinion, are of greater importance than these or likely to prove more beneficial to the people of this country if enacted into law.

Those whose views I wish to present are the chief executive officers of boards which have to do with the care of the insane and the mentally defective in the following states: Massachusetts, Rhode Island, New York, New Jersey, Pennsylvania and Maryland. In the public institutions of these six states are to be found nearly three-fourths of all the insane or mentally defective immigrants who are receiving public care in this country. In addition, I desire to speak for the following national or state societies devoted to the study of insanity and mental deficiency, the promotion of the care of those suffering from these conditions, or the prevention of mental diseases; the National Committee for Mental Hygiene, the American Medico-Psychological Association, the American Genetic Association, the Committee of One Hundred on Public Health, the New York Psychiatric Society, the Mental Hygiene Committee of the New York State Charities' Aid Association and the Eugenics Record Office. Properly accredited representatives of each of these State Boards and of each of these societies are in this room. Although what I have to say has the unqualified endorsement of all these gentlemen, each is ready to speak for his own State or for his own organization and to give any specific information which you may desire.

The states whose representatives are here today are literally staggering under the burden of caring for their insane. There are in all public institutions approximately 200,000 insane persons—a number exceeding the number of students enrolled in all the colleges and universities in this country. If all the states had provisions comparable with those existing in the most ad-

* Presented by Dr. Stewart Paton on behalf of a delegation representing State Boards of Insanity and national and local organizations for psychiatry and mental hygiene.

vanced ones, there would be more than 300,000 insane patients in the hospitals today. If there were added those in whom serious mental disease exists but is unrecognized, the number under treatment would reach half a million.

To this great number 60,000 new patients,—an army nearly as large as our regular army—are added every year. The cost of conducting the institutions in which this vast number of persons is cared for is so great that in several states it is exceeded only by the amount expended for education. In New York, the expenditures for the insane are one-fourth of the total annual appropriations of the state. Even with these great sums devoted to the care of the insane of the United States much remains to be done. In many states large numbers of these sick persons are not yet delivered from the misery and degradation of jails and almshouses and in very few states is our duty to the most unfortunate of the community's wards fully discharged. In the case of the mentally defective existing provisions are still more inadequate. It has been estimated by careful students of the subject that only 10% of all the feeble-minded are in suitable institutions. The others are unjustly confined in prisons and reformatories, inadequately cared for in almshouses or at large in the community, often a menace to the morals and to the safety of others and more often themselves the victims of greed or lust. Enlightened states are keenly aware of the importance of solving the great problem of providing for the mentally defective, but the magnitude of the task is such that our legislatures are reluctant to undertake it.

What can be said of the intelligence of a country which, just awakening to this vast problem and just stirring itself to deal with it, fails to take every necessary precaution to prevent the task being rendered still more difficult by a large and steady influx of the insane and the mentally defective of other lands? In requesting that Congress provide us with an immigration law under which the insane and mentally defective can be excluded, we cannot be accused of inhumanity. The gentlemen whom I represent are devoting their lives to the welfare of these persons. They are engaged constantly in the endeavor to render relief to those suffering from mental diseases more effective and more humane than it is at present, but when they see their institutions so over-crowded that patients have to sleep on the floors of wards and corridors, when year after year they see their charges suffer through the reluctance of legislatures to grant the great appropriations needed for proper care and treatment, and when they realize that the beds occupied by aliens could be filled at once by citizens waiting for treatment, can they be blamed for asking for better provisions in the immigration law? Aliens and citizens share alike in this great humanitarian work, but need this half-loaf be divided?

The states which I have named receive their population chiefly through immigration. The number of immigrants who come to New York State to settle permanently every year is greater than the number of babies born. The application, through eugenics, of the facts learned by the scientific study of human heredity will doubtless make it possible in years to come to cut off defective strains so that fewer babies who have inherited the mental defect of their parents will be born, but how weak are efforts in this direction compared with the enormous need! It is in the elimination of the insane and the mentally defective from the great tide which flows through Ellis Island that the most practical and humane field for the control of insanity and feeble-mindedness in this country is to be found.

It may be said that the present immigration law excludes the insane and mentally defective. In reply I have only to say that, under the present immigration law, our public institutions have been filled with the alien insane. There are serious defects in the immigration law and these defects have long been recognized not only by those who care for the alien insane and mentally defective in the public institutions of this country but by the medical authorities actually engaged in the examination of immigrants at our ports of entry. The amendments which I will read are endorsed not only by the state boards and medical organizations which are represented here today but by every national medical organization which is interested in psychiatry and by more than twenty state and local medical organizations.

They were framed with the constant guidance of experienced medical officers of the government service, who had discovered the inadequacies of the present immigration law in their daily work at Ellis Island. Together we have urged them upon the attention of Congress and the only opposition which they have received from any source has been from those steamship companies which are willing to bring to this country an unfortunate immigrant who can be persuaded to come and who can get through one of the convenient loop-holes in the present law.

Listed in the order of their importance, these are the amendments which we desire to advocate

1. Providing that medical officers of the United States Public Health Service who have had special training in the diagnosis of insanity and mental deficiency shall be detailed for duty at ports of entry designated by the Secretary of Labor and that the services of interpreters and suitable facilities for making mental examinations and observing cases shall be provided for these medical officers.

2. Providing that the surgeon of each vessel shall make a mental examination of each immigrant before accepting him for passage. (A physical examination only is required at present)

3. Providing a fine of \$200 for bringing to this country any insane or mentally defective

person whose condition could have been detected by a competent medical examination at the time of embarkation.

4. Adding constitutional psychopathic inferiority and chronic alcoholism to the excludable causes.

5. Making it mandatory for the Secretary of Labor to provide suitable attendants for immigrants being deported, when they require personal care on account of mental or physical disability.

6. Increasing from three to five years the period in which deportation of aliens who have become a public charge in this country can be effected—unless it can be affirmatively shown that their dependence is due to causes arising subsequent to landing.

7. Providing that deportation can be effected subsequently if proceedings are *instituted* within five years.

We advocate these amendments as medical men trained in the department of medicine which has to do with mental diseases. In our opinion, these provisions in the bill before you overshadow all others in importance and we especially desire to state that we are here solely for the purpose of presenting the reasons for their inclusion in the immigration law. Although other provisions in the law may be desirable and some may be inadvisable, we wish to confine ourselves strictly to those matters regarding which we have special knowledge. The amendments which we advocate deal with complex problems in a highly specialized branch of science and we have felt that the views of men who are devoting themselves to this work might be of value to you in forming an opinion as to the need of the amendments which I have read and as to the results likely to be gained by their adoption.

EARLY HISTORY AND SUPPRESSION OF THE OPIUM TRAFFIC.

REPORT from The Hague by way of London states that on February 12 the protocol of the anti-opium convention of 1912, at which 44 nations were represented, was signed by the delegates of the United States, China and the Netherlands. This convention aims at the suppression of the opium traffic and the illicit international traffic in cocaine and other habit-forming drugs; and its signature by these three representatives brings it automatically in force in the three respective countries having an approximate population of about 475,000,000 persons. Mr. Henry VanDyke who, as American Minister to the Netherlands, represented the United States as a signatory, made the following statement with reference to the convention:—

"The opium convention aims at putting a stop to the vicious trade in opium as an intoxi-

cant and at imposing the strictest regulation on the legitimate commerce in opium for purely medicinal purposes. I hope that the three nations which have taken the first definite step in this direction soon will be followed by many others. It is a great satisfaction that China, which has suffered most from the opium vice, has taken this step side by side with the United States, which is the foremost nation in adopting legislation against this vicious trade, and that Holland, with her immense possessions in the East Indies, should take the same stand."

The *Journal of the American Medical Association* for February 6 contains an important leading article by Dr. Macht on the early history of opium and some of its preparations and alkaloids, from which the following extracts are of particular interest in connection with the signature of this convention:—

"The medicinal properties of poppy juice date from a remote period. Recalling the highly developed culture of the ancient Egyptians one is inclined to imagine that the narcotic properties of opium were known to them; but the investigations of Unger (1857) have failed to trace any acquaintance with opium in Ancient Egypt, and Dr. Ember, of the Semitic Department of Johns Hopkins University, knows of no reference to it in Egyptian literature. According to some Hebrew scholars, there is a reference to poppy juice in the Bible. In several passages in the Old Testament the word *rôsh* is mentioned. Professor Haupt is convinced that *rôsh* means poppy, and so also is Professor Post. In the Talmud we have one reference to opium, under the name *ophion*, but that word was clearly borrowed from Greek. In the classical Hindoo literature there is found no reference to it. From the time of the Mogul Conquest on there appears a word *Khash-khash* which means poppy-seed, and *Khash-khasharasa*, juice of the poppy. In this it is easy to recognize our modern word *hashish*; and so it seems that at that early date the narcotics opium and cannabis indica were confused with each other. The original home of the poppy was in Asia Minor. From there it was carried to Greece at a later period.

"It is not at all certain whether Hippocrates was acquainted with the juice of the poppy. According to Wootton, he refers to a substance called *mecon* to which he attributes a purgative as well as a narcotic action. Some think that it was opium; others believe that he was referring to another plant. In any case, he made but very little use of the drug. The first authentic reference to the milky juice of the poppy we find by Theophrastus at the beginning of the third century B. C., when he speaks of it as meconion. Scribonius Largus, in his 'Compositiones Medicamentorum,' about the year 40 of the present era, describes the method of procuring opium from the capsules of the poppy, and about the year 77 of the same century Dioscorides makes a distinction between the juice of the capsules and the extract of the whole plant. He describes

the method of incising the capsules, and refers to adulterations of the drug with the milky juices of other plants so that it is evident that the collection of opium was quite an industry in Asia Minor at that time. Pliny devotes some space to a description of opium and its medicinal use, and the drug is mentioned repeatedly by Celsus in the first century and by numerous other Latin writers. Galen spoke enthusiastically of the virtues of opium confections, and the drug was soon so popular in Rome that it fell into the hands of shopkeepers and itinerant quacks.

"The introduction of the drug to the natives of the East was through the Arabs, and in the first instance to Persia. Its introduction to India seems to have been connected with the spread of Mohammedanism.

"The Arabic physicians used opium very extensively, and even wrote special treatises on some of its preparations. The earliest mention of opium as a product of India is by the traveler Barbosa, in 1511. A Portuguese historian, Pyres, in a letter to Manuel, King of Portugal, in 1516, speaks of the opium of Egypt and Bengal.

"Opium is supposed to have been brought to China first by the Arabs, who are known to have traded with the southern parts of the empire as early as the ninth century. Later the Chinese began to import the drug in their junks from India. It was not before the second half of the eighteenth century that the importation of opium began to increase rapidly through the hands of the Portuguese, and a little later through the famous East India Company. In 1770 the English established an opium depot in Lark's Bay, south of Macao, and the traffic rapidly increased, so that very soon the Chinese authorities began to complain, and in 1820 an edict was issued forbidding any vessel having opium on board to enter the Canton River. A system of contraband followed, then political friction between England and China, and the so-called Opium War, which culminated in the Treaty of Nanking (1842) by which five ports of China were opened to foreign trade, and in 1858 opium was admitted as a legal article of commerce. By that time the vice of opium-smoking had spread like a plague over the gigantic empire, and became so deeply rooted that, in spite of innumerable edicts and decrees, all efforts to check its growth have been powerless."

NAVAL SURGERY A CENTURY AGO.

IN a recent issue of the *British Medical Journal* are quoted abstracts from articles published in the July and October parts of the *Edinburgh Medical and Surgical Journal** for 1814, representing some experiences of naval surgery dur-

* *Edinburgh Medical and Surgical Journal*, Vol. x, pp. 265, 295, 311, 317, 325, 403, 419, 451, 453.

ing the close of the Napoleonic era a century ago:—

"There are three cases of gunshot wounds of the thorax, with annotations, by Joseph Arnold, M.D., surgeon, H. M. S. *Alcmene*. There is a fatal case of hydrothorax, with appearances on dissection, by Mr. Archibald Robertson, surgeon of H.M. S. *Cydnus*; there is the letter from Joseph D. A. Gilpin, M.D., inspector of army hospitals at Gibraltar, to Colin Chisholm, M.D., F.R.S., etc., on the fever which occurred at Gibraltar in 1813; and there are letters from Dr. Chisholm on yellow fever, and answers by D. Bancroft, written with some degree of heat; there is a report on the use of charcoal powders as a substitute for cinchona by R. Calvert, physician to the forces; there is a case of hemiplegia in a soldier in His Majesty's West India Regiment, treated with tinctura lyttæ (cantharides) and cold shower-bath, by Robert Hartte, surgeon to the forces; there are observations on pemphigus (in Russian sailors) by Dr. Dickson, physician and inspector of the fleet, etc., on the North American Station; and there are observations on the use of ipecacuanha and opium in dysentery, by Mr. William English, surgeon. In all these articles military matters are prominent; in fact, the atmosphere is that of war—war with its traumatisms and its subsequent plagues, pestilences, and famine diseases; war *matribus destituta*, but ameliorated, and with some of its worst sufferings mitigated by medical knowledge and surgical skill.

"Of Dr. Arnold's cases the second† was interesting, both from its medical and its general aspects. The wounded man was Christofolo Rodomere, a Venetian, rich in goods, and the owner of a vessel bound in May, 1812, from Venice to Bocca di Cattaro, passing therefore from Napoleon's 'Kingdom of Italy' to the Province of Illyria. Unfortunately for the vessel and for Rodomere, who was on board, one of His Britannic Majesty's frigates, cruising up and down in the Adriatic with her sailors on the look-out, sighted the Venetian. To be seen meant to be captured, 'not before her crew,' adds Dr. Arnold, with evident regret, 'which consisted of about a dozen persons, had killed or wounded twenty-seven of the frigate's men.' The frigate, one may judge, pretty nearly caught a Tartar on this occasion. Poor Rodomere, in a desperately wounded condition, was handed over to the surgeon, and he found that whilst his left thumb was badly shattered and his left side from hip to ribs was much bruised, a leaden ball had also entered near the tenth rib, three finger-breadths from the spine, and had come out about an inch below the nipple of the left breast. When he received the wounds he fell and spat up blood by coughing, 'but after this he became quiet, his pulse was moderate, his breathing free, and he did not complain of pain.' This happened on

† *Edinburgh Medical and Surgical Journal*, Vol. x, p. 274, 1814.

the night of May 22nd. He took three laxative pills, had cataplasms applied to his thumb and to the wound in the side, and saturnine lotion to the anterior wound. For the next few days he went on nicely; but on May 30th the anterior wound began to be tender, and a full inspiration gave pain, and Dr. Arnold was led to take stronger measures. These, in the Latin tongue, into which the surgeon was wont to diverge on such occasions, were as follows: 'Fluat ex templo sanguis ad 5xx; capt. etiam pilulas laxantes tres; pergat in usu cataplasmatum et aliorum.' On the next day he was worse, so Dr. Arnold again took steps: 'Iterum fluat sanguis ad 5xx; bibat ad voluntatem aquam succo limonum gratam redditam; sumat pilulas laxantes duas,' and so on. The patient got no better; indeed, on June 1st, when the dressings were removed, nearly 2 lb. of watery lymph tinged with blood and slightly fetid were discharged from the wound in the vicinity of the heart."

Apparently the bullet had been deflected and had passed around the chest under or along a rib. The man improved after July 22, and by the end of August was able to pull an oar in an open boat.

This Joseph Arnold, the author of these clinical records, was born at Beccles, England, in 1782. He received the degree of M.D. at the Edinburgh Medical School in 1807, and in 1808 entered the medical service of the British Navy. As a youth his chief interest had been in the natural sciences.

"Even on active service Arnold's instincts as a naturalist peeped out, as has been seen, in the interest he took in *Plantago lanceolata* in the treatment of hydrothorax; and, after the war was over and the navy reduced, he gratified his love of research, and at the same time occupied his professional talents by taking medical charge of the *Northampton*, bound to Botany Bay with convicts. During his travels he made a collection of insects from South America, New Holland, and the Straits of Sunda, and also wrote several journals of notes on zoological matters; but unfortunately all these were lost in the burning of the ship (the *Indefatigable*) by which he was proceeding to Batavia. Not daunted he made several excursions with Sir Stamford Raffles in Sumatra. He returned home in 1816, but only that he might the better prepare for further travels and zoological research in the East. Sir Stamford Raffles was by this time (1818) governor of Sumatra, and Arnold obtained employment as naturalist under him. During his second visit to this island he discovered the strange parasitic plant which grows on the wild vine, has neither stem nor leaves, but possesses a flower of great weight, measuring 3 ft. in diameter. Sir Stamford and Arnold are to this day associated together in the name which this plant bears, the *Rafflesia arnoldi*. Arnold also made a fine collection of fossils and shells, which he bequeathed to the Linnean Society, of which he had been

made a Fellow in 1815. He fell a victim to fever, however, at Padang, in Sumatra, in July, 1818, and died 'devoted to science and the acquisition of knowledge, and aiming only at usefulness.' "

Correspondence.

PARIS LETTER.

THE REHABILITATION OF THE HONORABLE PUS-BUG.

(From Our Foreign Correspondent.)

PARIS, FEB. 2, 1915.

"How are the mighty fallen! Tell it not in Gath . . . lest the daughters of the uncircumcised triumph."
"How are the mighty fallen in the midst of the battle! . . . I am distressed for thee, my brother Jonathan."—(II. Samuel, Chap. 1.)

Mr. Editor: There, you see; those sentiments are rather neat. A little knowledge of Scripture is not a bad thing, after all; and those lines express my feelings to a nicety. The true sportsman, the man who "plays the game," is supposed to be he who can take a blow without flinching, even with a smile, and who, when the fight is over, dismisses the matter entirely from his mind, shakes hands with his adversary, and harbours no malice. This beatific state of mind is observed in its most perfect form among the British; two statesmen, who during a week's debate have been moving heaven and earth each to demonstrate that the other is the blackest villain conceivable, will at the end be detected quietly dining with each other at some restaurant, to all intents and purposes on the friendliest of terms. *My* mentality is of the very contrary order; *my* Christian doctrine is never to forget an injury, but to try and repay my adversary, and with interest, even if it takes a lifetime. This is why at the present juncture my midriff is gently pulsating with sinful satisfaction, as I contemplate the depths of ignominy into which the surgical clan has suddenly fallen.

[To an audience of medical men it is superfluous to lay stress on the condition of inferiority, even of downright degradation, in which we have been living during the last few decades *vis-à-vis* to our surgical colleagues. Nor is it necessary to recall their airs of disdain, their mock humility: "Oh, I'm only a surgeon, I don't know anything about that," or the condescension with which they tolerate our presence at a distance, as we view them going through their sacred rites on the other side of a glass screen, even the circumambient ether in which they move being unfit for the vulgar to breathe: *procul, O procul est, profani!*]

When I think of the undoubted paradise in which these gentlemen of the knife have been accustomed to live, especially the younger set, who have seen only the aseptic era, and then compare it with the hideous gloom of Tartaros and Styx into which this war has suddenly plunged them, I try, but altogether in vain, to picture to myself what their frame of mind can be. At one moment to be firmly convinced that the millennium was at hand, that perfection had practically been attained, so that there was really nothing in the way of a surgical intervention that could not be undertaken with entire safety, so far as any danger from infection was concerned; at the next to realize that the clock had been suddenly set back fully fifty years, to see every wound in a large hospital oozing, weeping, even flowing into pus, and to feel that it was not safe so much as to sew up the flaps of a simple amputation.—"how are the mighty fallen," as I quoted in the beginning!

How those good old pus-bugs must be hugging themselves, to find themselves once more before the foot-

lights, and as star performers, if you please. For the whole crew of these phantoms of a bygone age have turned up smiling, from good healthy pus, *le pus louable*, as it used to be called, to all kinds of septic concoctions, virulent mixtures of varying degrees of malignancy, pus of pyocyanic tints (a thing I never saw in the old days, even in the dirtiest wards of the dirtiest surgeons, such as LeFort and Desprès), gangrenous organisms with or without gas, that acme of degradation hospital rot, and the scale of the erysipelas forms of septic virulence. Vatel is said to have committed suicide because the fish did not arrive in time for his mother's banquet; what conceivable form of harakiri ought these surgeons to indulge in, in presence of this lamentable catastrophe and the utter collapse of all their wonderful *Châteaux en Espagne*!

When I say that the wounds of these unfortunate soldiers suppurate, and all suppurate, I put the matter in the most sober terms, for from a large number of these wounds, particularly the jagged, deep and irregular shell-injuries, the pus simply wells up in a steady stream. One wonders where it possibly can come from! If you leave one of these cases only twenty-four hours under a dressing, the pus will have soaked through, wormed its way out under the edges, and have soiled nightshirt, pillow, sheet and even mattress! It is something fantastic. So these wretched surgeons are practically impotent, and contemplate this revival of the sway of the pus-bug with faces of horror and consternation; all they can do is to open up widely, remove fragments, foreign bodies, and tissue that must necessarily mortify, clean the region up,—and then let the wound suppurate until it has had enough. And this is their sole occupation from early morn till dewy eve, so that their inward feelings must be of a rather hectic tinge. For, if you will consider a moment, many of these young men, who have lived chiefly in regions where accidents are not apt to occur,—that is, away from factory districts, large railroad centers, etc.,—and whose practice has been in the main among the better-class civilians,—have scarcely ever seen a wound suppurate, even in the simplest manner; with modern operating-theatres, and a perfect technic, where would a surgeon's reputation be if his incision were to suppurate after an abdominal section or breast-removal! So at the present moment, if you have a surgeon friend and really wish to make him react, to see his body stiffen as the poor victims do in the Sing Sing electrocution chair, and to witness the high tension current escape from the points of his anatomy in forty cm. sparks, just ask him in an innocent way if it is true that the nurses in his ambulance have to wear indiarubber boots to keep out of the pus, or whether the authorities are really proposing to inquire into his high mortality-rate from hospital-rot!

We will now leave these filthy pigs to wallow in their blue pus and turn to our own part of the show and inquire how the medical fraternity has come out of the present ordeal.

Not so badly, on the whole. The remark was made by everybody, during the first three or four months of the war, that the morbidity was practically a negligible quantity, in comparison with the traumatisms,—that the sick-rate in the army was not any greater than, if indeed as high as, among the civilian population. In fact, you simply did not hear of any sick, only of the wounded. Of late, however, the situation has changed; but when you consider the conditions that have prevailed, the only wonder is that it is not many times worse than it is. For, remember that we have here to deal with a Latin people, none of whom stand anywhere, as compared with our Anglo-American requirements, either in personal cleanliness or habits of hygiene. Now when you think that these hundreds of thousands of men have been immobilized for well over two months in or back of lines of trenches dug in clay in a perfectly flat country only just above sea-level, with practically no drainage, while the entire region is polluted with myriads of decom-

posing and badly interred bodies of men and animals, and any such thing as proper scavenging is out of the question in the zone of firing, it is little short of a miracle that the various intestinal infections of a dysenterical or typhoidal variety should have remained as infrequent as they have. Two things, and two things alone, can be advanced to explain this unexpectedly favorable situation: The fact that a large number of men have been vaccinated for typhoid, and the fact that it has been midwinter, with incessant rain and no inducement to drink water. Had this situation arisen in midsummer, with endless dust, flies, and the thirsty men drinking just anywhere, we should in all likelihood have had a very different tale to tell. To those favorable factors must be added that the men have been well and intelligently fed, and that their spirits and confidence stand at *beau-fixe*,—both of these details being of prime importance as regards a man's receptivity for infectious disorders.

I imagine that when the figures come to be known it will be found that the results, as far as morbidity is concerned, will on this side of the line not bear comparison with those obtained by the Japanese in the Manchurian campaign, on account of the great difference in the hygienic customs of the two peoples: The Jap considers himself dishonored if he does not more or less boil himself in a cauldron every day of his life; whereas, if the Gaul ever washes it is because he has fallen in the river or been overtaken by a drenching rainstorm in the open. But at least, up to the present moment of writing, we have had nothing even remotely, to compare with what took place in South Africa during the first part of that war. However, we are only on the prelude of *this* war. So, perhaps, it will be wise not to give too great an air of finality to these remarks.

But a moderate amount of typhoid and dysentery is a mere nothing compared with the slough of despond of the surgical side; to be anywhere near on a footing with them we ought to have a big epidemic of typhoid, with the vermin-borne forms of typhus, spotted and recurrent, in addition; and this is precisely what we have *not* got, in spite of the fact that they say that the vermin in the fighting lines is something incredible. So far nothing has been heard of typhus, although it is indigenous in the regions from which so many of the African troops have been brought. In former days typhus generally occurred in besieged cities, prisons and famine-stricken districts. Here again the proper nourishment of the troops, together with their cheerfulness and enthusiasm, may have acted as a powerful deterrent under certainly most unfavorable general conditions.

So that it is quite fair to sum up and claim that on the whole, and taking a wide view of the entire situation, the medical side of this war has come out perhaps better than it deserved to,—a point that I may, perhaps, touch on in a future letter. The question is whether this situation is likely to continue to the end; whether when the heat comes, or if the allies begin to move over regions that have been contaminated by their adversaries for months and months, their health will remain at its present high standard. This is more than anyone can foretell; we can only wait and see.

"S."

TRANSFUSION IN THE TREATMENT OF RUPTURED TUBAL PREGNANCY.

Boston, February 10, 1915.

Mr. Editor: Judging by the editorial in the *JOURNAL* of Jan. 28, 1915, in which issue my paper on "Emergencies of Extrauterine Pregnancy" was published, I fear my attitude toward blood transfusion was misunderstood. The point which I wished to emphasize especially in regard to the use of some fluid to replace the blood loss, was that the fluid

should be introduced in such a manner as to be gradually absorbed. In the cases where this has been carried out, the recoveries from anemia have appeared to be more rapid. There is also a danger in the sudden introduction of a large amount of fluid into the blood vessels, as by this procedure the strain on the heart is increased and the composition of the blood changed. Where salt solution has been given intravenously, there has often been a deterioration in the appearance of the patients a day or two following operation, which did not seem to be present to such a degree in those who had gradually absorbed the fluid either from the subcutaneous tissues or from the rectum. In one or two instances the heart seemed to be affected by the increased work thrown upon it, or by the change in the blood.

In regard to blood transfusion, it was stated in my article that my experience with it in this class of cases was limited to two individuals, but that in these two cases blood transfusion showed no advantage over the use of salt solution; judging from the appearance of the patients a day or two after operation.

I am not opposed to blood transfusion as such, and the only reason it has not been used in some instances has been the lack of a donor, but in the two cases mentioned above, it seemed to me that there was a distinct indication of hemolysis. My remarks were meant to be confined to these two individuals, and not intended as a general statement, although there is a question in my mind whether the intravenous use of either blood or salt solution is always beneficent in these cases.

Very truly yours,

ERNEST B. YOUNG, M.D.

434 Marlborough Street.

F. F. SIMPSON, M.D., *Treasurer.*

An American gentleman who saw the food and clothing put into the hold of the steamship, *Lynorta*, which took supplies, for the State of Virginia, to the Belgians, crossed the Atlantic on the ship and went into Belgium to watch the distribution of the articles among the people. He has returned and declares: First, that every pound of flour and every article of clothing sent from America by the Relief Commission is received by a Belgian; and second, that all who get such gifts are in direct need of them. Hunger seems to have broken down all class distinctions in Belgium.

Physicians and their families have shared the common fate. Appeals for food, drugs, and clothing are numerous and urgent. The resources of your Committee have been so limited that we have not felt justified in sending anything but food to our starving Colleagues; 156 physicians and 11 medical societies have thus far contributed to this fund. There are approximately 142,300 physicians in the United States. If each one would contribute even a small sum, it would be possible to supply the necessary food, drugs, and clothing. Do not hesitate because your check is not as large as you would like it to be. Contributions of any amount will be welcome.

Every cent you give will be economically spent for supplies for Belgian physicians and their families. There are no charges for shipping and distribution.

Not a cent has been spent for stenography, stationery, stamps, or other accessory.

CHANGES IN THE MEDICAL CORPS, U. S. NAVY, FOR THE FIVE WEEKS ENDING FEB. 12, 1915.

January 18, P. A. Surgeon E. V. Valz, to Naval Hospital, Portsmouth, N. H.

January 21, Surgeon H. E. Odell, detached, Naval Hospital, Canacao, to Naval Hospital, Yokohama, Jap.
P. A. Surgeon F. E. Porter, detached, Naval Hospital, Yokohama, to U.S.S. *Cincinnati*.

A. Surgeon D. C. Post, detached, *Palos*, to *Quiros*.

A. Surgeon M. B. Hiden, detached, Naval Hospital, Canacao, to *Palos*.

Surgeon J. C. Thompson, to Navy Recruiting Station, San Diego, Cal.

Surgeon J. M. Brister, detached, *Utah*, to Atlantic Reserve Fleet.

Surgeon J. F. Murphy, detached, *Montana*, to home and wait orders.

Surgeon H. D. Wilson, to *Utah*.

Surgeon M. K. Johnson, to *Montana*.

Surgeon F. E. McCullough, detached, Naval Training Station, Newport, to Naval Training Station, San Francisco.

Surgeon D. N. Carpenter, detached Bureau of Medicine and Surgery, to Naval Training Station, Newport.

January 22, P. A. Surgeon F. G. Abeken, detached, Naval Station, Guam, to U.S.S. *Supply*.

A. Surgeon G. W. Calver, detached, *Supply*, to Naval Station, Guam.

January 28, P. A. Surgeon M. C. Baker, to Naval Station, New Orleans, La.

February 1, A. Surgeon Louis Lehrfeld, Resignation accepted effective January 29, 1915.

February 4, P. A. Surgeon C. M. George, detached, Pacific Torpedo Flotilla, to home and wait orders.

February 5, A. Surgeon H. V. Cornett, to Naval Hospital, Canacao.

P. A. Surgeon Wm. Chambers, to Naval Station, Olongapo.

A. Surgeon L. H. Roddis, to Naval Hospital, Canacao.

February 6, Surgeon J. C. Pryor, detached, *North Dakota*, to *Montana*, connection, Regiment Marines.

P. A. Surgeon L. M. Schmidt, detached, *Louisiana*, to *Montana*, connection, Regiment Marines.

February 9, P. A. Surgeon J. G. Ziegler, detached, *West Virginia*, to Pacific Torpedo Flotilla.

February 11, Surgeon W. S. Hoehn, detached, Pacific Reserve Fleet, to *Colorado*.

APPOINTMENTS.

It is announced that Dr. S. H. Chuan, a graduate of Harvard University, has been appointed Surgeon-General of the Chinese Empire and elected president of the Chinese Army Medical college at Tien-tsin.

Dr. George Lovell Gulland, M.A., B.Sc., F.R.C.P.E., has been appointed professor of medicine in the University of Edinburgh.

Dr. J. A. Murray has been appointed acting director of the British Imperial Cancer Research Fund, succeeding Dr. Bashford who has recently resigned on account of ill health.

The officers of the various sections of the New York Academy of Medicine for the year 1915 are as follows: Dermatology and syphilis, Dr. Charles M. Williams, chairman, Dr. Walter J. Heilmann, secretary; surgery, Dr. Clarence A. McWilliams, chairman, Dr. John Douglas, secretary; neurology and psychiatry, Dr. Israel Strauss, chairman, Dr. Foster Kennedy, secretary; pediatrics, Dr. Walter L. Carr, chairman, Dr. Royal S. Haynes, secretary; otology, Dr. C. D. Van Wagenen, chairman, Dr. John A. Robinson, secretary; ophthalmology, Dr. H. H. Tyson, chairman, Dr. George H. Bell, secretary; medicine, Dr. T. Stuart Hart, chairman, Dr. Nellis B. Foster, secretary; genito-urinary diseases, Dr. Leo Buerger, chairman, Dr. A. R. Stevens, secretary; orthopedic surgery, Dr. Arthur H. Cilley, chairman, Dr. P. W. Roberts, secretary; obstetrics and gynecology, Dr. LeRoy Brown, chairman, Dr. George W. Kosmak, secretary; laryngology and rhinology, Dr. Hubert Arrowsmith, chairman, Dr. Francis W. White, secretary.

RESIGNATION.

Dr. William H. Park, director of laboratories of the New York Department of Health has resigned his administrative position as dean of the New York University Medical College, but will continue there as professor of bacteriology and hygiene.

NOTICES.

Physicians visiting the city will be cordially welcomed at the following clinics on the days and hours specified.

BOSTON CITY HOSPITAL.—After January 1, 1915, public operations will be performed in the Surgical Amphitheatre each week, on Thursdays, Fridays and Saturdays, at 10 o'clock.

Thursday: First Surgical Service, Dr. Blake.

Friday: Third Surgical Service, Dr. Nichols, and Fourth Surgical (G-U) Service, Dr. Thorndike.

Saturday: Second Surgical Service, Dr. Lund.

CARNEY HOSPITAL.—Dr. Bottomley and Dr. Mahoney will hold an operative surgical clinic every Wednesday at 9 A.M., and at the same hour on the same day Dr. W. R. MacAusland will hold an orthopedic clinic. All physicians are welcome to attend.

MASSACHUSETTS GENERAL HOSPITAL.—1. A surgical clinic Tuesday, at 12, in the out-patient amphitheatre. 2. Operations in the Bigelow amphitheatre Saturdays from 10 to 1. 3. Operations in the Surgical Building except Sunday, from 9 to 1. 4. Daily

surgical ward visits at which visiting physicians will be welcome. 5. Clinic in medicine and pathology Tuesdays at 12, by Drs. R. C. and H. Cabot and O. Richardson. 6. Medical clinic Thursday at 12, by Dr. D. L. Edsall.

PETER BENT BRIGHAM HOSPITAL.—Physicians visiting the city will always be cordially welcomed at the Peter Bent Brigham Hospital.

The medical visit takes place regularly every morning beginning at 10 o'clock.

Operations are usually going on throughout the forenoon in the surgical amphitheatre.

The surgical clinic is held in the clinical amphitheatre on Wednesdays at 12.30 P.M.

The medical clinic is held in the clinical amphitheatre on Mondays at 12.30 P.M.

The clinico-pathological demonstration is held in the clinical amphitheatre on Fridays at 3.30 P.M.

MASSACHUSETTS GENERAL HOSPITAL.—A medical meeting, open to the medical profession, will be held at 12 noon on Monday, March 1, 1915, in the lower amphitheatre of the out-patient department. Entrance on Fruit street. 1. Exhibition of cases. 2. Dr. J. H. Wright. A study of the inhibitory action of syphilitic serum on the formation of thrombin as compared with the Wassermann test. 3. Dr. G. C. Shattuck. A study of percussion dullness and the cardiac border. 4. Dr. J. H. Means and H. L. Higgins. The effect of drugs upon respiration in health.

F. A. WASHBURN, M.D., *Resident Physician*.

SOCIETY NOTES.

NEW ENGLAND PEDIATRIC SOCIETY.—The thirty-sixth meeting of the New England Pediatric Society will be held in the Boston Medical Library, Friday, February 26, 1915, at 8.15 P.M.

1. "Typhoid Fever in Children," Dr. Karlton G. Percy, Boston.

2. "Homogenized Milk. Its Possible Uses in Infant Feeding," Dr. Maynard Ladd, Boston.

3. Luetic Bursopathy of Verneuil. Report of a Case. Congenital Type," Dr. William P. Cones, Boston.

4. "Some New Symptoms in Amaurotic Family Idiocy," Dr. Isador E. Coriat, Boston.

Light refreshments will be served after the meeting.

E. M. BUCKINGHAM, M.D., *Pres.*

RICHARD M. SMITH, M.D., *Sec'y.*

THE HARVEY SOCIETY.—The ninth lecture of the series will be given at the New York Academy of Medicine, 17 West 43rd street, on Saturday evening, February 27th, at 8.30 P.M., by Prof. R. R. Bensley, University of Chicago. Subject, "Structure and Relationship of the Islets of Langerhans and Criteria of Histological Control in Experiments on the Pancreas."

BOOKS AND PAMPHLETS RECEIVED.

Speculation on the Stock Exchanges and Public Regulation of the Exchanges. An address delivered before the American Economic Association at Princeton, N. J., December 29, 1914.

The Story of Bethlehem Hospital from Its Foundation in 1247. E. G. O'Donoghue. E. P. Dutton & Company, 1915.

Morris's Human Anatomy, edited by C. M. Jackson, M.D. Fifth edition. P. Blakiston's Son & Co. 1915.

The Diagnostics and Treatment of Tropical Diseases, by E. R. Stitt, M.D. P. Blakiston's Son & Co.

Selected Addresses on Subjects Relating to Education, Biography, Travel, etc., by James Tyson, M.D. P. Blakiston's Son & Co.

The Balneo-Gymnastic Treatment of Chronic Diseases of the Heart, by Professor Theodor Schott, M.D. P. Blakiston's Son & Co.

THE CARNIVOROUS AND HERBIVOROUS TYPES IN MAN:

THE POSSIBILITY AND UTILITY OF THEIR RECOGNITION.*

I. INTRODUCTION AND OUTLINE.

BY JOHN BRYANT, M.D., BOSTON.

In a previous paper,¹ some account was given of the general considerations which led to the present studies, together with methods and the amount of work done upon the subject suggested by the above title. At about the same time, May, 1914, a bibliography² was presented, which in a broad way covered the various aspects of the literature. The time now devoted to the problem has been extended to about three years. A total of some five hundred post-mortems have been observed in this period, chiefly in Berlin and Hamburg, upon which it is expected to make some detailed remarks when the present series of papers has been concluded. In addition to the pathological work, many patients have been seen in the hospitals here and abroad, and much valuable information has been gained through conversations with numerous able American and European clinicians.

On the basis of this preparation, there has been constructed the provisional outline which follows. It is by no means to be considered as

final, but it at least provides a method of classification open to proof, and it is felt that it can be corrected and amplified until it has become of distinct value as an aid to clinical medicine, from the point of view not only of diagnosis and treatment, but of prognosis and, still more important, of prevention.

There are of course innumerable ways of classifying the human race. Some one has divided it into those in pursuit of truth and those in pursuit of happiness. Bean has suggested a logical and scientific classification upon the basis of the three germ layers, but this involves three divisions. Can the human race for descriptive purposes be split into two contrasting halves? With his usual perspicacity, the common man has settled the question in the way most obvious to him by employing the terms thin and fat, as witness such nursery rhymes as "Jack Spratt and his wife." It will be shown that this is a sound classification, since it is an outward manifestation of structural differences grouped in the present work under the heading of type: carnivorous and herbivorous. It would be manifestly absurd to claim any originality for the use of these two words. They have been used for scores, almost hundreds, of years as the basis of a broad classification of the lower animals, and Treves and many other workers both before and after him have pointed out that from a developmental point of view man lies midway in the scale between these two extremes; but there the matter has rested.

It is now proposed to apply this old comparative anatomy classification to the genus homo, and to attempt to show not only the logic of its application, but the extent to which it may be made useful: herein lies whatever of originality there may be in the present studies: but credit for

* Being Contributions from the Psychopathic Hospital Number 66 (1915.3). The article was presented in abstract at a meeting of State Hospital physicians and others held at the Psychopathic Hospital, January 4, 1915. (Bibliographical Note.—The previous contribution, Number 65 (1915.2), was by Robert M. Yerkes, entitled "The Importance of Social Status as Indicated by the Results of the Point Scale Method of Measuring Mental Capacity," submitted to the *Journal of Educational Psychology*.)

originality is beside the point, for the only question at issue, upon which it is hoped to stimulate discussion is the following: Is the classification here presented of value to clinical medicine?

Among the facts in comparative anatomy which may be taken as proved by work recorded by others in the literature, may be mentioned the following:

1. Body form influences intestinal length, regardless of food habits.

2. Intestinal length varies with the species, regardless of food habits.

3. In a given species intestinal length may vary 100%.

4. This variation depends chiefly upon the digestibility of the food.

5. Offspring of one mother have at birth approximately the same intestinal length.

6. In a given adult individual of one species body form and intestinal length are dependent chiefly upon heredity, the form or digestibility of the food presented during the growing period, and the general habits of life. Sex plays an almost negligible part in this regard.

7. The carnivorous or herbivorous habit is not obligatory. Animals predisposed by their species to one or the other of these extremes of food habit, may within wide limits when forced by necessity reverse their normal manner of life, being thus as it were facultatively carnivorous or the reverse. For example, the polar bear may be forced to live upon kelp, and the cow may exist in comparative comfort upon fish.

8. In the group of mammals, the carnivora are distinguished by a long thin body form, and a short simple type of intestine in which the small intestine is markedly longer than the colon. The herbivora, on the other hand, present a marked contrast; the body form is short and thick, and the intestine long and complex, with the small intestine perhaps barely equal in length to the colon.

In man, the intestine is of intermediate character, nearer to the carnivora than to the herbivora, but here also one finds extremes of difference in intestinal length amounting as in the lower animals to at least 100% at a given age or height.

If now one attempts to divide the genus homo itself into the two groups of herbivorous and carnivorous, the contrast is more striking when the group "omnivorous" is omitted, and since it is merely a combination, always in varying proportions, of the other two factors, its use is confusing. An additional reason for omitting "omnivorous" from a medical classification is that man is normally omnivorous, and the normal man is usually healthy. Medicine is concerned chiefly with the abnormal, the "sports" of development. Much of our progress is doubtless due to these same sports, but to them the ordinary life and ordinary food of the normal man are ill adapted. They require special care for maximum efficiency, and since food is the chief essential to life, the regulation of the diet

in these sports becomes a matter of considerable moment. The direction of the change in these cases is usually away from the ordinary or mixed diet, and in the direction of a predominatingly meat or vegetable diet, according to the indications of one or the other type suggested by the body form. The extremes of these types in man present almost as great contrasts as do the tiger and the hippopotamus in the jungle and the zoological garden.

If one could go no further than to say that type is proven in the lower animals and that it is susceptible of proof in man, the whole proposition would remain as a museum curiosity. If, however, it can be applied to clinical medicine, it must remain a live issue. It would, for instance, be worth while if it could be shown that by mere observation, before using instruments of precision, one could state even approximately that a given patient has probably had or is likely to have had certain diseases and not others, that his present complaints are so and so, and that in the future this person will be subject to say high blood pressure hypertrophic arthritis or gall-stones, and that person to tuberculosis, atrophic arthritis, or leukaemia. That some at least of these diagnoses and prognoses are possible is suggested by the contents of the following differential tables, and it is hoped that they may prove of interest not only to the physician, but to the employer of labor, and to the life insurance actuaries who must deal so largely, so to speak, in futures.

The tables which follow are arranged, in default of a better method, in alphabetical order, and are intended to bring out the contrasts between the two types in question; therefore they are presented at first, with a minimum of reading matter, and will be followed in later issues of this JOURNAL by papers dealing at more length with their contents when repetition will be much less obvious. It is perhaps sufficient for the present to point out two general principles.

The first may be called the law of contrasts, for it seems that where one can prove a given point for one type, its opposite may be expected to prove true in the other type. So-called normal anatomy seems to have been based chiefly upon the herbivorous type. The consideration of the numerous mixed types is purposely omitted from this paper.

The second general principle is, that in a broad way the herbivore would appear from a study of the tables as a positive and the carnivore as a negative organism. The carnivore in short may be regarded either as an inferior or as a very highly specialized organism, for in him the only systems developed or remaining present in excess, are those necessary to the perpetuation of the species: the central nervous system, and the reproductive system. In this connection, it is perhaps worthy of remark that the majority of persons who had reached advanced age before appearing in the series of autopsies referred to,

seemed to be decidedly of the carnivorous type. Extremes in variation of organs, appear also to occur often within the limits of this type.

References to the literature will be given in the later consideration of the tables, but only in cases of special interest, or when sources have not already been indicated in the two papers previously mentioned. Statements for which no other authority is to be found, may be considered as based upon personal observations.

HERBIVOROUS.		TABLE I.		CARNIVOROUS.	
		BILIARY.			
Amount secreted, large.....	Plus BILE	Minus	Less abundant	
Passes through liver to bile.....	Plus	CHOLESTERIN*	Minus	Retained in circulation by liver acting as a filter. Amount in bile small.	
With liver large.....	Plus	.. CIRRHOSIS ..	Plus	With liver small.	
Muscular, small, thick.....	Minus	GALL BLADDER GLYCOCHOLIC	Plus	Atrophic, large, thin, ptotic.	
Present in relatively small amounts	Minus ACID*	Plus	(C ₂₂ H ₄₃ NO ₆).	
		(Contains no sulphur)			
Large, high, transverse.....	Plus LIVER	Minus	Small, low, perpendicular.	
May be pure cholesterol.....	Plus	.. GALL-STONES ..	Plus	Stones, if present, always of infectious origin.	
		TAUROCHOLIC			
(C ₂₆ H ₄₅ NO ₇ S).....	Plus ACID*	Minus	Present in relatively small amounts.	
		(Contains sulphur)			

* Facts true for the lower animals.

HERBIVOROUS.		TABLE II.		CARNIVOROUS.	
		CARDIO-RENAL.			
Cholesterol deposits in retina.....	Plus	ALBUMINURIC .. RETINITIS ..	Minus		
Large	Plus AORTA	Minus	Small.	
Apoplexy	Plus	ARTERIO-SCLEROSIS ..	Minus		
	Plus	... ASCITES ...	Minus	Cardio-renal disease less frequent.	
May be extremely high.....	Plus	BLOOD PRESSURE	Minus	Usually low.	
Blood content high.....	Plus	CHOLESTERIN	Minus	Blood content lower.	
High	Plus	.. DIAPHRAGM ..	Minus	Low.	
	Minus	EOSINOPHILES	Plus	Often +	
Large, transverse	Plus	... HEART	Minus	Small, perpendicular.	
	Minus	... LEUKEMIA ..	Plus	Usually in this type.	
	Minus	LYMPHOCYTES	Plus	Usually +	
Large, high	Plus	... KIDNEY	Minus	Small, low.	
High tension, fast, full.....	Plus	... PULSE	Minus	Low tension, slow, weak.	
		RED BLOOD			
Hemoglobin and count high.....	Plus	.. CORPUSCLES ..	Minus	Hemoglobin and count low.	
		STATUS-			
	Minus	LYMPHATICUS	Plus	Always of this type.	

HERBIVOROUS.		TABLE III.		CARNIVOROUS.	
		CHEMICAL.*			
Easily fatal. No formation of NH ₄ from proteids.....	Plus	... ACIDOSIS ...	Minus	Not easily fatal. NH ₄ formed in considerable amounts.	
In urine +.....	Plus	... CALCIUM ...	Minus	Usually only small amounts.	
Percent. in blood and supra-renal high	Plus	CHOLESTERIN	Minus	Percent. in blood and supra-renal low.	
Large, light, acid, fermentative....	Plus	... FAECES	Minus	Small, dark, alkaline, putrefactive.	
		GLYCOCHOLIC			
Relatively small amounts in bile...	Minus ACID	Plus	Large amounts in bile.	
		(C ₂₂ H ₄₃ NO ₆)			
		HIPPURIC			
In urine +.....	Plus ACID	Minus	Usually absent in urine.	
Usually absent in urine.....	Minus	... INDOXYL ...	Plus	In urine often in large amounts.	
Formed only from dextrose.....	Minus	... LACTOSE ...	Plus	Formed from proteid also if necessary.	
		NITROGEN			
Decreasing with length of fast.....	Minus	ELIMINATION	Plus	Constant during fast.	
Usually small amounts only.....	Minus	PHOSPHATES	Plus	In urine +	
		TAUROCHOLIC			
In bile +.....	Plus ACID	Minus	Relatively small amounts in bile.	
		(C ₂₆ H ₄₅ NO ₇ S)			
Usually small amounts only.....	Minus	... UREA	Plus	In urine +	
Always present but in traces only..	Minus	.. URIC ACID ..	Plus	Amount varies with diet: may be high or absent.	
		NITROGEN			
Normally alkaline or neutral.....	Minus	... URINE	Plus	Normally acid.	
Not limited.....	Plus	URINARY ACIDITY	Minus	Limited.	

* Known to be true in the lower animals, and probably true in human types.

TABLE IV.

HERBIVOROUS.		DUCTLESS GLANDS.		CARNIVOROUS.
Small	Minus	... GENITAL ...	Plus	Large, reproductive functions +
May be large or cystic: adiposis, gigantism, acromegaly.....	Plus	.. HYPOPHYSIS ..	Minus	Variations slight.
Usually large.....	Plus	.. PANCREAS ..	Minus	Usually small.
Calcium balance normal.....	Plus	.. PARA-THYROID ..	Minus	Tetany not infrequent.
Normal or large.....	Plus	.. THYMUS ...	Minus	Usually deficient, may be very large.
Myxoedema	Minus	.. THYROID ...	Plus	Exophthalmic goitre.
Always large, especially cortex.....	Plus	.. SUPRA-RENAL ..	Minus	Always small, vagotomy frequent.

TABLE V.

HERBIVOROUS.		DIGESTIVE.		CARNIVOROUS.
Usually of acquired type, especially in region of gall bladder.....	Plus	.. ADHESIONS ..	Plus	Largely congenital as veils, also flexure adhesions frequent.
Small at base, short, tubular.....	Minus	.. APPENDIX ...	Plus	Large at base, long, conical.
Usually fulminating, often fatal....	Plus	.. APPENDICITIS ..	Plus	Usually chronic and mild.
Long, large, high.....	Plus	... COLON	Minus	Short, small, low.
Atonic; sympathetic stimulation in excess causes decreased peristalsis	Plus	.. CONSTIPATION ..	Plus	Spastic; vagus stimulation in excess causes increased peristalsis.
		DUODENAL		
Rare	Minus	... ULCER	Plus	Frequent.
Rare	Minus	GASTRIC ULCER	Plus	Frequent.
		HEPATIC		
Normal	Minus	.. FLEXURE ...	Plus	High or absent.
		ILEO-CAECAL		
Normal position, firmly attached...	Minus	... VALVE	Plus	High or low, loosely attached.
Muscular, long, thick walled.....	Plus	.. INTESTINE ..	Minus	Short, thin walled.
Infrequent, acquired.....	Minus	... PTOSIS ...	Plus	Frequent, congenital.
		RATIO, COLON		
May be as 1 : 1.....	Plus	TO SMALL IN-	Minus	Often at 1 : 5, never as 1 : 1.
		TESTINE		
Usually short.....	Minus	SIGMOID LOOP	Plus	Usually long, may reach to diaphragm.
		SPLENIC		
Normal	Minus	... FLEXURE ...	Plus	Often high, rarely very low.
Normal, transverse.....	Minus	.. STOMACH ...	Plus	Tubular, long or dilated, often low.
Sympatheticotony its antithesis....	Minus	.. VAGOTONY ..	Plus	Always in this type.

TABLE VI.

HERBIVOROUS.		DIET.		CARNIVOROUS.
		CARBO		
Normal diet.....	Plus	.. HYDRATES ..	Minus	Easily cause gas formation.
Normally acid, fermentative, large.	Plus	... FAECES	Minus	Normally alkaline, putrefactive, small.
Normal diet.....	Plus	... FATS	Minus	Easily cause fat indigestion.
Easily taken in excess.....	Minus	.. PROTEIDS ..	Plus	Normal diet.

TABLE VII.

		EYE.		
		ALBUMINURIC		
Visible cholesterin deposits.....	Plus	.. RETINITIS ..	Minus	
Visible cholesterin deposit.....	Plus	.. ARCUS SENILIS ..	Minus	
	Minus	.. ASTHENOPIA ..	Plus	With general asthenia.
Cholesterin a factor?.....	Plus	.. CATARACT ..	Minus	
Pupil large.....	Plus	CILIARY MUSCLE	Minus	Pupil small.
	Minus	CONGESTIONS	Plus	Due to poor circulation?
Iris angle wide, lymph flow not obstructed	Minus	.. GLAUCOMA ..	Plus	Lymph outflow easily obstructed.
	Minus	.. HYPEROPIA ..	Plus	Low blood pressure.
		INTER-OCULAR		
Nose wide, flat.....	Plus	.. DISTANCE ..	Minus	Nose thin, prominent.
High blood pressure.....	Plus	... MYOPIA	Minus	
Cholesterin a factor?.....	Plus	.. OPACITIES ..	Minus	
External	Plus	... SQUINT ...	Plus	Internal.
Visible cholesterin deposits.....	Plus	.. XANTHOMA ..	Minus	

TABLE VIII.

HERBIVOROUS.		HABITS AND DISEASES.		CARNIVOROUS.
Light wine or beer with low alcohol content, if alcohol is used at all	Minus	... ALCOHOL ...	Plus	Brandy or whiskey and other distilled liquors with high alcohol content preferred.
		DRUGS	Plus	As morphia and cocaine.
Starches, greens, vegetables.....	Plus	... FOOD	Plus	Meats, greens, no starches.
Prefers sugar to alcohol.....	Plus	... SUGAR	Minus	Prefers alcohol to sugar.

HERBIVOROUS.		TABLE VIII. (Continued.)		HABITS AND DISEASES.		CARNIVOROUS.	
Infrequent, acute, severe, more often fatal		Plus	..	INFECTIONS ..	Plus	Frequent, chronic, mild, seldom fatal.	
Ulcer and gumma.....		Plus	..	SYPHILIS ..	Plus	General paresis and tabes.	
Cardio-renal and mesenchymal tissues		Plus	..	SYSTEMIC ..	Plus	Central nervous system, gastro-intestinal tract, skin, or other epithelial structures.	
		Minus	..	TUBERCULOSIS	Plus	Pulmonary, in over 90% of cases occurs in this type.	

HERBIVOROUS.		TABLE IX.		LYMPHATIC.		CARNIVOROUS.	
		Minus	..	GLANDS ..	Plus	Frequently enlarged.	
Normal		Minus	..	LEUKAEMIA ..	Plus	Usually in this type.	
Small		Minus	..	SPLEEN ..	Plus	Small or large.	
		Minus	..	TONSILS ..	Plus	Often large.	

HERBIVOROUS.		TABLE X.		MENTAL.		CARNIVOROUS.	
Systemic changes, slow onset, usually quiet		Minus	..	DISEASES ..	Plus	Acute onset, sudden psychoses, often violent.	
Deductive, slow, persistent.....		Minus	..	MENTALITY ..	Plus	Inductive, active, changeable.	

HERBIVOROUS.		TABLE XI.		ORGANS.		CARNIVOROUS.	
Heavy		Plus	BONE	Minus	Light.	
Normal		Minus	BRAIN	Plus	Large, rarely very small, in relation to body weight.	
		Plus	..	GASTRO-INTESTINAL ..	Minus	Short, simple.	
Long, complex		Minus	..	GENITAL ..	Plus	Always relatively in excess.	
Thin, light.....		Minus	HAIR	Plus	Thick, dark.	
Large		Plus	HEART	Minus	Small.	
Large or cystic.....		Plus	..	HYPOPHYSIS ..	Minus	Often small.	
Large		Plus	..	KIDNEY	Minus	Small.	
Large		Plus	..	LIVER	Minus	Small.	
Usually expanded, often emphysematous		Plus	LUNGS	Minus	Usually compressed, often atelectatic.	
Normal		Minus	..	LYMPHATIC ..	Plus	Nodes often enlarged or deficient.	
Short, thick		Plus	..	MUSCLES ..	Minus	Long, thin.	
Small		Minus	..	OVARY	Plus	Always large, often cystic.	
Large		Plus	..	PANCREAS ..	Minus	Small.	
Small		Minus	..	PENIS	Plus	Large.	
Often hypertrophied.....		Plus	..	PROSTATE ..	Minus	Usually small.	
Thick, moist, pink.....		Plus	SKIN	Minus	Thin, dry, sallow, pigment +	
Normal		Minus	SPLEEN	Plus	Large or small.	
Large, especially fatty cortex, pigment layer usually +.....		Plus	..	SUPRA-RENAL	Minus	Small, with narrow cortex, pigment usually absent.	
Small		Minus	TESTES	Plus	Large.	
Normal or large		Plus	..	THYMUS	Minus	Small or very large.	
Small, often deficient		Minus	..	THYROID	Plus	Large, often ++	
Large, often myomatous.....		Plus	..	UTERUS	Minus	Small.	

HERBIVOROUS.		TABLE XII.		PHYSICAL.		CARNIVOROUS.	
May be large throughout		Minus	..	ABDOMEN ..	Plus	Prominent only below umbilicus.	
		Minus	..	ADAM'S APPLE	Plus	Prominent.	
Never in this type.....		Minus	..	ASTHENIA ..	Plus	Also neurasthenia, myasthenia, etc.	
Large		Plus	..	ANKLE	Minus	Small.	
Broad, flat		Plus	BACK	Minus	Narrow, round.	
Heavy		Plus	BONE	Minus	Light.	
Normal or large from congestion...		Minus	..	BREAST	Plus	Absent or large and pendant.	
Rounded		Minus	..	CHEEKBONE ..	Plus	Prominent.	
Square		Plus	CHIN	Minus	Pointed, long or short.	
Usually good		Plus	..	CIRCULATION	Minus	Usually bad, extremities frequently cold and often purple in color.	
Wide		Plus	..	COSTAL ANGLE	Minus	Very narrow.	
Thick, wide, simple.....		Minus	EAR	Plus	Thin, long, convoluted.	
Thick, short		Minus	..	EXTREMITIES	Plus	Thin, long.	
Far apart.....		Plus	EYES	Minus	Close together.	
Often excessive.....		Plus	FAT	Minus	Usually deficient.	
Short, wide.....		Minus	..	FINGERS ..	Plus	Long, tapering.	
Short, wide.....		Minus	..	FOOT	Plus	Long, tapering.	
Usually square.....		Plus	..	FOREHEAD ..	Minus	Often receding.	
Wide, often square.....		Minus	HAND	Plus	Long, tapering.	

TABLE XII. (Continued.)

HERBIVOROUS.		PHYSICAL.		CARNIVOROUS.
Normal, round, square or sugar-loaf	Plus HEAD	Minus	Long, large, rarely microcephalic.
Short, thickset.....	Minus HEIGHT....	Plus	Tall, lanky.
Often very large.....	Plus HIPS	Minus	Usually small.
Often emphysematous.....	Plus LUNGS	Minus	Often atelectatic.
Heavy, short, thick, muscle belly long and tendon short.....	Plus	... MUSCLES ...	Minus	Slender, long, thin, muscle belly short and tendon long.
Short, thick, muscles heavy.....	Minus NECK	Plus	Long, thin, muscles slender.
Short, wide, flat.....	Minus NOSE	Plus	Long, thin, prominent.
Arch low.....	Minus	... PALATE...	Plus	Arch high.
Wide, flat, rigid.....	Plus PELVIS ...	Minus	Small, round, flexible.
Usually slight.....	Minus PIGMENT...	Plus	Often excessive.
Usually acquired if present.....	Minus	... PTOSIS ...	Plus	Usually present, often congenital.
Normal, flat.....	Minus	... SCAPULAE ..	Plus	Angel wing.
Heavy, wide, square.....	Plus	... SHOULDERS ..	Minus	Usually narrow, sloping.
Thick, pink, moist.....	Plus SKIN	Minus	Thin, sallow, dry.
Abundant, odorless, alkaline.....	Plus SWEAT	Minus	Scanty, offensive, acid.
Full, tubular, barrel-shaped.....	Plus	... THORAX ...	Minus	Flat, peg-top.
Seldom small.....	Plus WAIST	Minus	Often very small.
Often excessive.....	Plus	... WEIGHT ...	Minus	Usually deficient.
Thick	Plus WRIST	Minus	Thin.

TABLE XIII.

HERBIVOROUS.		REPRODUCTIVE.		CARNIVOROUS.
Normal or large from congestion...	Minus BREAST	Plus	Absent or large and pendant.
Small, seldom cystic.....	Minus OVARY	Plus	Large, cysts frequent and may be of great size.
Small	Minus PENIS	Plus	Large.
Hypertrophied frequently.....	Plus	.. PROSTATE ..	Minus	Small.
Labor often difficult; pelvis rigid, flat	Minus	REPRODUCTION	Plus	Labor usually easy; pelvis flexible, round.
Small	Minus TESTES ...	Plus	Large.
Large, frequently myomatous.....	Plus	... UTERUS ...	Minus	Small.

TABLE XIV.

HERBIVOROUS.		SKELETAL.		CARNIVOROUS.
Hypertrophic	Plus	.. ARTHRITIS ..	Plus	Atrophic.
Heavy	Plus BONE	Minus	Light.
Wide	Plus	COSTAL ANGLE	Minus	Narrow.
Wide	Plus	COSTO-VERTEBRAL ANGLE	Minus	Narrow.
When present, usually occurs in this type	Plus	LUMBO-SACRAL JOINT INVOLVEMENT	Minus	
Wide, rigid, flat.....	Plus PELVIS ...	Minus	Narrow, flexible, round.
Heavy, wide	Plus	VERTEBRAL PROCESSES	Minus	Light, narrow.
	Minus	SACRO-ILIAC JOINT INVOLVEMENT	Plus	When present, usually occurs in this type.
Heavy	Plus	. VERTEBRAE .	Minus	Light.

THE ROENTGEN DIAGNOSIS OF GALL-STONES BY IMPROVED METHODS.

By LEWIS GREGORY COLE, M.D., NEW YORK,

Professor of Roentgenology, Cornell University Medical College;

AND

ARIAL W. GEORGE, M.D., BOSTON,

Assistant Professor, Department of Roentgenology, Tufts College Medical School, Boston.

Up to about three years ago gall-stones were detected by the Roentgen method of examination in such a small percentage of the suspected cases that most Roentgenologists, including ourselves, did not recommend the examination, and made it only when urged to do so. Several of us found, however, that gall-stones containing calcium could be detected much more frequently

than we had supposed, and this discovery stimulated the search for them. As yet, only a few Roentgenologists had published reports on gall-stones.¹ In 1913, however, four observers reported almost simultaneously that gall-stones could be detected Roentgenographically in from 50 to 70% of the cases in which they were really present.² This estimate of the percentage of gall-stones was obtained in two ways. Case reported detecting 50 in 1000 cases. Cole reported detecting 20 in 499 cases. As these observations were made during about the same period, and each reported independently of the other, it was significant that the percentage was almost identical in the two reports.

It is a well recognized fact that gall-stones are found in 10% of all adult cases submitted to post-mortem examination, and as we were able to detect them in 5% of the cases in a routine

gastro-intestinal examination, we therefore concluded that we could find them in about one-half of the cases where they were present.

Pfahler estimated that he could detect gall-stones in 74% of the cases, which according to him, was 24% more than could be obtained by other Roentgenologists.

His percentage was based on 29 cases operated on for gall-stones, in 27 of which stones were found. He had reported findings in twenty of these, but had been unable to detect them in seven where they existed, and in two cases he had reported probable stones wherein no stones were found,—a record of nine erroneous diagnoses.

Therefore, what Pfahler really reported was 31% of erroneous diagnosis, rather than a percentage of accuracy.

When stones are detected by Roentgen methods, an operation for their removal is almost universally assured, and unless there are errors in interpretation, the stones are found. But if no stones are found through these methods, the operation is not so likely to be performed, and of this case one has no knowledge of whether or not stones are present. Therefore such a method of estimating the percentage is not accurate.

A series of cases might be examined, however, in the manner employed by Brewer and Cole,³ in gastro-duodenal lesion, viz: If by using all other methods combined, the surgeon determines that gall-stones are present, he will operate for them regardless of the Roentgen findings. The Roentgenologist makes his examination, making a definite negative or positive diagnosis exclusively on the Roentgen findings and the operation, and then compares the findings. This method of estimating would give one an accurate percentage of the cases that are detectable by Roentgen rays.

Among the Roentgen plates exhibited at the last meeting of the Roentgen Ray Society, George showed 15 cases of gall-stones, each presenting faint shadows of the calculi. Some of these were so indistinct that even a keen observer would have failed to detect them, and Cole was even doubtful of the significance of the shadows in some cases, although in a previous communication,⁴ he himself had described and attempted to illustrate an article on gall-stones with two or three similar Roentgen plates.

Since we have paid close attention to the gall-bladder region in the routine gastro-intestinal examinations, studying the cases observed by this method, and reviewing previous Roentgen plates of the gall-bladder, much valuable information has been obtained which has led us to believe that we can detect stones at least twice as frequently as before. After having considered that we detected them in 50% of the cases, it would now appear that we can show them in all cases where they are present.

One of the writers (Cole) now believes that far more than 10% of the cases presenting themselves for a Roentgen examination of the stomach

and the gall-bladder region, have gall-stones, and therefore that one is not justified in estimating the percentage of detectable gall-stones in the manner previously employed by him and Case. Having once made this error, Cole hesitates to base the percentage of detectable gall-stones on anything less than such a test as that employed by Brewer and Cole on gastro-duodenal lesions. But we believe this method is sufficiently accurate to justify a careful Roentgen examination of every patient over forty, who complains of gall-bladder or gastric symptoms.

A positive Roentgenologic diagnosis can be made in such a large number of the cases where gall-stones are present, that the negative diagnosis has become far more important than it was previously considered to be.

The technic is not radically different from that employed for soft tissue detail in any other part of the body; but it requires conscientious attention to the most minute points, and one must not be satisfied with the Roentgen plates, unless detail is shown to the greatest possible degree. Roentgen plates obtained by improved technic, show extraordinary detail; in two cases even the pelvis of the kidney, the blood-vessels going to and from it, and the upper part of the ureter were remarkably distinct.

Our opinions differ as to the advisability of catharsis prior to the examination. One of the writers (George) considers that the gas usually resulting from a cathartic is a more disturbing factor in the interpretation of the Roentgen plate than the fecal content of the colon. This, he thinks, may aid in determining the location of the gall-bladder. His colleague (Cole) on the other hand, thinks that a thorough catharsis and total abstinence from food for twelve hours prior to the examination is very essential; also that the gas in the colon often serves to accentuate the calculi, and in a previous communication,⁵ he has advocated the artificial injection of air into the colon in some doubtful cases as a means by which shadows of gall-stones may be accentuated or identified.

The use of the Coolidge tube enables one to obtain an accuracy of penetration which is unattainable with a standard tube. Roentgen plates showing brilliant bone detail with considerable density of the soft parts are not desirable for the diagnosis of gall-stones. Soft "monotonic" Roentgen plates obtained with the Coolidge tube, are deprecated by some critics because marked contrast in the bony structure is lacking; but they show remarkable gradations in the soft tissue—a result for which one strives when in search of gall-stones.

Minor condemned fine Roentgen plates of the lungs as compared with the fluoroscopic image, because they showed so much detail in the soft parts as to make them difficult to interpret. It is the interpretation of these very details that increases the accuracy of diagnosis, whether it

be the chest or gall-bladder that is under consideration.

One of the co-authors herein (Cole) strives to obtain this detail by using a small focal point tube of a penetration just sufficient to cast an image on the screen beneath the patient, and makes the exposure long enough to obtain the desired density of the Roentgen plates, whilst his colleague, (George), considers speed an important factor, and uses a fairly large focal point with varying penetration, making the exposure so short that it practically eliminates the effect of the involuntary motions of the body, particularly gastric and intestinal peristalsis and pulsations of the blood vessels.

The necessity of using an extremely small cone, showing only a limited area in each Roentgen plate is strongly emphasized. The length of the cone is not an essential factor. By means of such a cone secondary rays are generated in the patient to a much less degree, and the fogging effect being proportionately diminished it is then possible to show distinctly a calculus that would be quite invisible if a large or moderate sized blend were used. The cone may be pointed obliquely downward, so that the axis of the rays is parallel with the under surface of the liver. When this is done, the under surface of the liver appears as a clear cut and well defined line; and the gall-bladder, if normal, can usually be detected, or the relation of the patient to the tube may be altered by a slight rolling from side to side. Sometimes, particularly when the gall-bladder is high, a lateral position will show the gall-stones against the background of the liver.

It matters very little whether screened or unscreened plates are used. Some plates may be made with screens, and some without them. The unscreened plates should be exposed face to face, and slightly undertimed, with a view to matching up the shadows thereon after development. Double screened plates also may be made in a special holder, constructed to carry screens of different rapidity. Two plates and two screens of different speed are used in the same holder. The plates are placed back to back. The under one face down, lies against a fast screen, whilst the upper one lies face upward against a relatively slow and thin screen. A very short or even undertimed exposure is made, and after development the plates are superimposed and matched together, whereupon by transmitted light one gets the plastic effect up to a certain point. This method eliminates screen and plate defects to a great extent.

Roentgen stereoscopy adds very materially in the interpretation of the Roentgen plates. Four exposures may be made, preferably with each exposure on the two plates face to face, giving a slight lateral shift to the tube between the first and second exposures. Then move the tube down about two inches and make two more exposures, shifting the tube once more in the lateral direction between the third and fourth. In this manner, one can stereoscope the various exposures

with each other, that is to say, 1-2 and 3-4 stereoscoped with each other laterally; and 1-3 and 2-4 stereoscoped with each other vertically.

Comparison from behind avails little; but small areas may be brought close to the plate for detailed examination, by the use of a circular plate-holder about the size of the end of a small compression blend. This holder, with or without a screen, may be pushed up under the edge of the rib, thereby materially diminishing the thickness of that part of the abdomen.

The entire region from the eleventh rib to the crest of the ileum or even lower, should be included in the examination. As repeated exposures are required, and as some of the plates are not screened, the total exposure is considerable, and a filter should always be used to prevent dermatitis. If after careful study of at least fifteen or twenty Roentgen plates of the gall-bladder, no evidence of the calculi is found, the patient should be submitted to an examination of the stomach, duodenum, and colon, in a search for adhesions from cholecystitis without stones, or for the purpose of differentiating this condition from post-pyloric ulcer and appendicitis with reflex gastric symptoms.

Even when there is direct evidence of the stone, this additional information is of great value in determining whether or not there is a concomitant lesion, whether or not surgery is indicated and how difficult the operation may be.

Although the technic herein described greatly facilitates the interpretation of the Roentgen plates, gall-stones may be detected in the ordinary Roentgen plate, in a large percentage of cases if one is familiar with their Roentgenographic appearance.

Of late, a re-examination has been made of those Roentgen plates taken during the last four or five years in which direct evidence of gall-stones was insufficient or undetected, but which showed enough evidence of adhesions from the accompanying cholecystitis to justify surgical procedure. In the re-examination, our increased knowledge of the Roentgenologic appearance of soft gall-stones has enabled us to detect direct evidence of the calculus on the Roentgen plate, in a large number of cases where calculus was found at operation.

The same results have been obtained from a re-study of those cases where the gall-bladder only was examined, and a negative diagnosis was made. The gall-stones found at operation in these patients can now be identified in the original Roentgen plates. The evidence was there before, but we were then unable to recognize it.

Of all the aids to be suggested for detecting calculi, the method of matching together the shadows by superimposing one Roentgen plate over another, as described in a previous communication,⁶ is probably the most important. By far the best illumination can be obtained by holding the plate obliquely at an arm's length

against the northern sky. A concave lens or better still a pair of opera glasses used in the reverse direction, will accentuate contrasts. For examining a small area, a magnifying glass may be helpful, especially in identifying the faceted side of small calculi.

A lantern slide made of superimposed Roentgen plates, will sometimes accentuate the contrast and bring out details not observed in the original plates. Thus very faint shadows may sometimes be shown well enough for lantern slide demonstration or reproduction; whereas others cannot be demonstrated or reproduced for publication, because the shadows concentrated on the slides are diffused by enlargement.

Identification of the gall-bladder aids materially in the detection of calculi, and is a detail which one should always try to obtain. It can be detected in nearly every case where it exists, normal in size or dilated. The gall-bladder may be found anywhere from the region of the eleventh rib to the fifth lumbar vertebra. In one case, it was located as far down as the sacrum. As a rule, it will be seen below the lower border of the liver. If, after taking a number of Roentgen plates, the gall-bladder is not found in the normal position, it can sometimes be located when a subsequent bismuth examination is made, by noting the position of the transverse colon.

Roentgenographically, gall-stones are divided into two definite groups: (1) Stones which contain considerable calcium, and (2) Cholesterine stones which contain no calcium, or only a trace of it. Gall-stones containing a large proportion of calcium can be shown without much difficulty and are sometimes so dense as to be mistaken for renal calculi.

The dense calcareous gall-stones are a type of calculi infrequently found; this perhaps explains why the study of gall-stones has made little advance since they were first observed. By far the greater number of gall-stones consist of cholesterine nucleus, with a calcareous coating, or *vice versa*. When the peripheral concretions are thin, which is true in about 50% of the cases, the stones are difficult to detect. With increasing density of the coating, the ring-like appearance is proportionally more marked and relatively easier to discover; but it is probably safe to say that the absolutely pure cholesterine stone is a rare entity⁷.

Unless unusual care is used in making and interpreting Roentgen plates, cholesterine stones containing only a trace of calcium will be entirely overlooked in the future, just as they have escaped observation in the past. It is not the shadow producing quality of the stone as a whole that concerns us in this class of case, but rather the shadow cast by the long diameter of the periphery of the stone. Whether the stone be faceted, spherical or a combination of both, on some particular diameter there will be sufficient density to cast a peripheral shadow. This explains in part why a single Roentgen plate

of a series will often reveal a perfectly characteristic gall-stone, whereas all previous plates of the same region show only questionable shadows. If each individual stone in a mass of small stones does not cast a well-defined shadow, the shadow of the entire mass will often give the clue.

The interpretation of suggestive shadows in the region of the gall-bladder is fraught with difficulties, similar to those experienced when positive diagnosis of kidney stones was first attempted. The present accuracy in diagnosing renal stones is the result of experience gained through numerous errors. Some of the disturbing factors in the gall-bladder region, such as intestinal contents, calcified mesenteric glands, costo-chondral ossification, and stones in the kidney and liver, have been enumerated in previous articles.⁸ Recent experience has added to our knowledge of possible pitfalls. Food in the cap is a particularly confusing finding, because its density corresponds to the faint shadow of a stone, and its size and position add to the illusion. Upon minute examination, however, it will be found that the shadow of food in the cap lacks the ring-like circumference of the cholesterine stone with a calcareous shell; neither has it the homogeneous character of the calcium stone, but is rather mottled in appearance. Moreover, it is usually possible to completely identify the shadow by tracing the outlines of the adjoining pars pylorica. Where the shadows are obscure several Roentgen plates matched together, will increase the density. A disturbing element of the same character is food contained in a single haustrum of the colon at the hepatic flexure. Being broad at one end and tapering to a fine point at the other end, it resembles an almond-shaped calculus. Abstinence from food eliminates results from this error.

Another interesting finding, and one which is visible only to the eye trained to pick up the slightest variation in density, is the presence of little rings, often no larger than a good sized pinhead, sometimes found in groups, sometimes isolated, in varying shapes of round, oval, or even quite irregular form. It is quite possible that these infinitesimal findings are the walls of bloodvessels seen in cross section.

It is a mistake to study Roentgen plates when they are wet, not only because reflected light cannot be avoided, but also because there is risk of damaging the plate.

A careful study of the clinical history of cases in which gall-stones are definitely shown by Roentgen methods, reveals the futility of expecting the classical gall-bladder symptoms to agree with the Roentgen diagnosis.

Before the advent of the x-ray, renal colic and renal calculi were considered almost synonymous terms. But surgical procedure for renal colic in cases where no calculus was shown on the Roentgen plate, eventually proved that only about one fourth of the cases having typical attacks of renal colic had a calculus of suffi-

cient size to be found by surgical exploration. On the other hand, only about one fourth of the cases in which kidney stones were definitely demonstrated by Roentgen methods, had anything simulating renal colic.

Our present experience indicates that the same observation will hold true in the gall-bladder region: that only when a gall-stone passes or engages does it cause the typical gall-stone colic, and this is relatively rare compared with the frequency of gall-stones.

The clinical indications of cholecystitis compare with those of pyelitis, except that one does not detect the presence of pus in the stools as readily as he detects it in the urine. Some of the cases of gall-stones give practically no characteristic symptoms of gall-stones, but are associated with obscure gastric or neurotic symptoms.

Therefore, any case presenting gastro-intestinal symptoms with absence of Roentgen evidence of an organic lesion of the stomach or intestines, should be submitted to a careful Roentgen examination of the gall-bladder. This is particularly true if, as Deaver suggests, the patient is "fair, fat and forty, and belches gas."

It is much easier to detect the stone in this class of case, than in thin, wiry, poorly nourished people who have no fat to outline the gall-bladder, and whose muscle is nearly as dense as bone. In persons under twenty-five, the peripheral coating of the stone is not usually dense, and the stone is so soft that it does not show even a dim peripheral ring or edge. Post operative cases with extensive adhesions, carcinoma of the liver or gall-bladder, and ascites also render negative diagnosis exceedingly difficult if not impossible.

Diagnostic accuracy is directly in proportion to the care exercised in making the examination, and one's experience in detecting and interpreting the findings. Statistics are of little value until thousands of cases have been observed by methods as careful and detailed as those described above. By that time the value of the method will be generally acknowledged, and statistics will not count for any more than they do now in cases of renal calculi or fractures.

The Roentgen method of diagnosing gall-stones has become so accurate that if there is no direct Roentgen evidence of gall-stones, or indirect evidence of adhesions involving the stomach, cap, duodenum, or colon, as a result of cholecystitis, the surgeon should have a preponderance of clinical evidence as a warrant in operating for gall-stones.

RESUMÉ.

1. Until within three or four years, gall stones were rarely detected by Roentgen rays.
2. During the last few years several Roentgenologists, including ourselves, consider that they have detected gall-stones in about 50% of

the cases examined. This was estimated in different ways by different men.

3. Experience has shown that gall-stones may be detected about twice as frequently as formerly by: (a) A special technic for making the Roentgen plates; (b) A minutely careful study of the Roentgen plates by various methods; (c) A thorough intimacy with the Roentgenographic appearance of gall-stones.

4. By applying the new method of interpretation, gall-stones have been detected on many Roentgen plates made by the old technic, and formerly diagnosed as negative.

5. By means of the special technic for making and interpreting Roentgen plates, a positive diagnosis may be made in so many cases, that the negative diagnosis has become of considerable significance.

6. Much care and study will be necessary to properly interpret the additional detail which can be obtained by the special technic, and undoubtedly some erroneous diagnoses will be made. (Cole has made two such erroneous diagnoses in the last month, and has thereby learned to differentiate the food in the cap and the feces in the haustra of the colon from evidence of calculi.)

7. If there is no direct Roentgen evidence of gall-stones, the stomach, cap, duodenum and colon should be examined for adhesions from an accompanying cholecystitis.

8. If there is no direct or indirect Roentgen evidence of gall-stones, the clinical history should be more characteristic than usual before one resorts to surgical procedure.

A STUDY OF THE EFFICIENCY OF MIXED TOXINS (COLEY) IN INOPERABLE SARCOMA. A CRITICAL ANALYSIS OF 134 MICROSCOPICALLY PROVEN CASES.

BY TORR WAGNER HARMER, M.D., BOSTON,

Assistant in Anatomy, Harvard Medical School; Junior Assistant Surgeon, Children's Hospital; Assistant in Surgery, Massachusetts General Hospital.

IN the BOSTON MEDICAL AND SURGICAL JOURNAL of August 13, 1914 (Vol. clxxi, pp. 253-261), I published a paper based upon observations made during the past five years upon 91 cases treated with mixed toxins of erysipelas and bacillus prodigiosus.* Some of these cases were under treatment too short a period to be of value in determining the efficiency of the toxins. Some were early cases in the series in which the doses were too small. Some cannot be traced by letters, visits to former homes, state or city records. Some were cases in which no pathological report was obtained. Some were cases of microscopically proven carcinoma. Some were cases of proven sarcoma in which toxins were administered as a prophylactic against recurrence after operations which might of themselves have cured (amputations without demonstrable metastases, etc.). Obviously in a critical analysis to determine the efficiency of toxins in the treatment of sarcoma such cases were excluded. There remained 32 cases. These were analysed; first, according to the type of sarcoma, and second, according to the anatomical situation and tissue of origin. These 32 cases were all primary or recurrent inoperable sarcoma, or cases in which the disease could not be eradicated by operation. All were proven by microscopic examination. All were under treatment at least three weeks. In all cases the results were free from vitiation by concurrent treatment (x-ray, radium, arsenical preparations, etc.). All living cases had been seen or heard from within three months.

The purpose of this study was to determine, if possible, the type or types of cases in which this treatment offered expectation of benefit. Obviously the answer to this question obtained by an analysis of so small a series of cases could be only suggestive. Despite many failures the most rigorous criticism of certain hopeless inoperable cases in which growths have permanently disappeared and no metastases have occurred must admit apparent cure attributable either to the toxins or to spontaneity. Factors are concerned of which we have no knowledge, and spontaneous cures have doubtless occurred. The percentage of apparent cures occurring with the use of toxins seems, however, too large to attribute to spontaneity. On account of a comparatively small percentage of most encouraging results an effort has been made in this paper

* I wish to express my appreciation to members of the staff of the Massachusetts General Hospital through whose courtesy this study was made possible.

to assemble a larger series of cases of sarcoma treated with the toxins in order to make more trustworthy deductions regarding their efficiency. To this end there have been added to my previously reported cases a few personally treated since the former publication and certain cases reported by Dr. Coley which have conformed to the criteria adopted in my earlier paper. Dr. Coley kindly sent me a copy of his address before the Third International Conference of Cancer Research held at Brussels in August, 1913. His monograph may be divided into five parts, viz.: the use of mixed toxins in inoperable sarcoma (81 cases), their use as a prophylactic after operations (9 cases), their use in inoperable carcinoma (8 cases), their use in the hands of other men (12 cases), and a tabulation of 125 cases also treated by other men. Our present inquiry is not concerned with use of the toxins in carcinoma nor as a prophylactic after operation. All of the other cases, 218 in number, have been abstracted and tabulated, as far as possible, after the manner of my own cases. Dr. Coley's recent paper on Sarcoma of the Long Bones in the *Annals of Surgery*, (1914, vol. lx, Nov., pp. 537-566) contains four cases not included in his Brussels address. These have been added, making a total of 222 cases. The data recorded has been, name or number of patient, age, sex, occupation, clinical diagnosis, duration of disease before operation or toxin treatment, history of trauma or irritation, nature of operation, interval between operation and toxins, size of growth before operation, size of growth when toxins started, site of injections, pathological diagnosis, tissue of origin, duration of treatment, maximum dose, character of reactions, effect of toxins on size and consistency of the growth and on pain, remarks of interest, and end result.

Only those cases in which data are given, which conform with the criteria adopted for an analysis of my own cases, have been selected for this series. In other words, all cases must have been proven by microscopical examination; all must have been primary or recurrent inoperable sarcoma, or cases in which the disease could not be eradicated by operation; all must have been under treatment at least three weeks; all must have been free from concurrent treatment (x-ray, radium, arsenical preparations, etc.). Of the 222 cases which have been abstracted 100 have been chosen as suitable for this analysis. Perhaps I have been very critical and have excluded cases which by others might have been judged worthy of consideration. The question is vital. The toxins have merit but the treatment is distressing. I believe, therefore, that conclusions furnished only by most rigorous criticism should be accepted.

Following the plan pursued in my previous paper I have arranged the cases in six groups determined by the effect of the toxins.

Group A includes those cases in which there was no appreciable effect. There were 12 cases.

Group B. includes those cases in which the growths softened but did not appreciably diminish in size. This softening may be fairly attributed to the toxins rather than to increased vascularity and cellularity associated with rapid growth; for it occurred at the site of the injections. There were 5 cases.

Group C includes those cases in which growths disappeared or practically disappeared, but returned. There were 20 cases.

Group D includes those cases in which growths disappeared but metastases simultaneously occurred. There were 10 cases.

Group E includes those cases in which growths diminished in size but still persisted. In this group have been included those cases in which inoperable masses have been so reduced that operations have subsequently been performed. A very few cases of this description have shown upon pathological examination no remaining trace of sarcoma. Such cases, in which the pathological reports have been made by pathologists of repute, have been included in Group F, apparent cures.

Growths treated with mixed toxins may disappear either by undergoing marked necrosis (becoming soft and fluctuant), by what appears to be simple absorption (probably the same process as the first but absorbing as fast as broken down so that no fluctuant tumor occurs), or by acute inflammation followed by resolution with a resulting fibrous mass. The latter process has been demonstrated microscopically in a series of photomicrographs in my previous paper.* A period of inflammation is followed by one of young connective tissue and blood vessels resulting eventually in fibrous tissue. The tumor in such cases is destroyed by an inflammatory process. With this microscopical evidence it seems fair to consider such cases apparent cures. All other cases with residual masses that have not been examined microscopically have been included in Group E. There were 14 cases.

Group F includes those cases which are apparent cures in which growths have disappeared and no metastases have occurred. There were 73 such cases.

Again following the plan pursued in my previous paper these 134 cases have been analyzed; first, according to type of sarcoma, and second, according to the tissue of origin or anatomical situation.

TABLE I.

ANALYSIS OF CASES ACCORDING TO TYPE OF SARCOMA.

Group	A	B	C	D	E	F	Totals
Spindle cell.....	2	1	5	1	1	22	32
Fibro sarcoma ..	2				3	4	9
Round cell.....			4	1	4	14	23
Small	1	1	8	2	2	13	27
Large	3		1	1	1	6	12
Melanotic				5		1	6

Giant cell.....	1	1			1	11	14
Mixed cell.....	3	2	2		1	5	13
Leiomyoma					1	1	2
Angiosarcoma					1		1
Hypernephroma ..						1	1
Totals.....	12	5	20	10	14	73	134

In Table I* is shown an analysis according to the type of sarcoma.

Spindle Cell Sarcoma. It so happened in my previously recorded cases that the pathologists' reports indicated the type of spindle cell, small or large. This distinction was, therefore, made in the previous analysis. It was interesting to note that of the three cases of each type there were no apparent cures of the small cell type, whereas there was one of the large cell type. This distinction of the size of cell may not be important. It is seldom made in Coley's case reports. In this present analysis, therefore, both have been assembled under the head spindle cell. The term fibrosarcoma, however, has been retained. Of the former there appears 22 apparent cures, of the latter four; a total of 26 cases, that is, about 36% of the total number of apparent cures.

Round Cell Sarcoma. In my previously reported cases a differentiation between small and large round cell cases was made. This has been followed, as far as possible, in this series. In a considerable number this distinction is not made, so the general term round cell has been used. The apparent cures include 14 cases of round cell, 13 cases of small round cell, and one case of large round cell; a total of 28 cases or about 39% of the total number of apparent cures. I am interested to note only one apparent cure of large round cell type. In my previous paper I made the observation that of about an equal number of cases of each type there were no apparent cures of the large cell type, whereas there were two of the small cell type. This larger series apparently substantiates this observation. The treatment of inoperable round cell sarcomata with mixed toxins, therefore, offers reasonable expectation of benefit, especially the treatment of the small round cell type.

Melanotic Sarcoma. In the previous series of cases it was observed in cases with multiple melanotic growths that individual tumors might be destroyed but coincident with this local benefit untreated tumors were increasing in size and new metastases were forming. All cases fell in Group D. One case, however, in which the treatment of a single large melanotic growth was undertaken lived for two years and two months. This case was given the largest single dose I have seen recorded, 52 minims. He displayed great tolerance for the toxins. The prognosis appeared favorable, as previously reported, until a spree of nineteen days was indulged in. After

* I am indebted to Mr. E. S. Brown of the pathological laboratory at the Massachusetts General Hospital for his care and skill in the production of these pictures.

* In the tables both my successes and my failures have been recorded. The full title of Coley's Brussels address, however, shows that he wished principally to set forth cases successfully treated. Some failures, however, were included. These tables, therefore, cannot be accepted as showing the proportion of failures and successes.

this his tolerance was greatly diminished so that only a dose of 4 or 5 minims could be given and metastases in various tissues appeared in quick succession.* I was led to state that the toxins offered no expectation of benefit in cases of multiple melanotic growths but that they might be legitimately tried in cases with single melanotic growths. It is interesting to note in this larger series that five of the six cases fall also in Group D and that the other case, that of Dr. Greenwood of Leeds, England, was a single large growth. This case is an apparent cure, the only cure of a melanotic case that has come to my notice. These facts seem curiously to substantiate the conclusions previously made from observations of a smaller series of cases.

Giant Cell Sarcoma. There is much disagreement at present regarding the nature of these growths. Certain pathologists and surgeons maintain that they are true malignant tumors, i.e. capable of forming metastases (Coley, Eve, Maybury). Others admit that such growths are prone to recurrence but deny them malignancy in the sense of forming metastases. The name giant cell tumor (Bloodgood), instead of giant cell sarcoma, has, therefore, been suggested. Again Barrie, of New York, believes that the process is only inflammatory, an osteomyelitis. Without discussing these opinions it is true that many cases of this condition can be cured by one or more curettings or resection. Other cases on account of size or situation may require amputation. Still others, probably the smallest group, cannot be cured by surgery alone. I refer in particular to more or less extensive involvement of the vertebrae. In considering growths originating in the medullary cavity of bone it is to be remembered that some may arise from endosteum and others from marrow elements. It is to be remembered that osteoclasts are present and these, I believe, may be regarded as foreign body giant cells of endothelial origin. The presence of some giant cells in medullary tumors is, therefore, to be expected. It is to be remembered that some of these tumors remain limited to bone. They may be expansile but for a long period remain localized. Spontaneous fractures may occur and heal. This class may be regarded as one type of bone cyst and considered myxomata. We are all familiar with another type which more quickly ruptures the bone, invades the soft parts, grows with great rapidity, often to considerable size, and not infrequently causes death. In selecting cases for this series I have had this type of case in mind. The term giant cell sarcoma has, therefore, been retained. Finally these medullary growths do not, in the majority of cases at least, conform with the condition commonly called osteomyelitis.

In my previous series were reported four cases which it seemed fair to regard as giant cell sarcomata. Two of these were apparent cures.

* A detailed account of this case with photographs and photomicrographs is given in the BOSTON MED. AND SURG. JOUR., 1914, Vol. clxxi, No. 7, August 13, 1914.

There have been added in this series ten cases including nine apparent cures, making a total of eleven apparent cures. The character of these cases, as shown in the case epitomies at the end of the paper, will, I believe, justify the use of mixed toxins in selected cases. Certain cases are appropriately treated by one or more curettings, others by resection, and still others on account of their size or situation by amputation. The records seemed to justify a preliminary trial of toxins in carefully chosen cases in which slowly growing tumors have ruptured more or less extensively into the soft parts rather than the immediate sacrifice of the limb. If such treatment is practised, the patient should understand that amputation may ultimately be necessary, and it should not be long deferred in the advent of increased rapidity of growth, repeated hemorrhages, considerable absorption, or superimposed infection. By this method with skilful judgment a few limbs apparently have been saved.

A small group on account of anatomical situation (more or less extensive involvement of the vertebrae) defy surgical eradication. These, I believe, should be submitted primarily to surgical attack, followed immediately by toxin treatment. The records justify the use of the toxins in such cases.

Mixed Cell Sarcoma. Under this head have been assembled cases with pathological returns of osteosarcoma, spindle cell osteosarcoma, chondrosarcoma, osteochondrosarcoma, etc. It has never been my good fortune to benefit with the toxins any cases of this class. This series, however, shows five apparent cures, viz: mixed cell tumor of the parotid, round and spindle cell sarcoma of the uterus, chondrosarcoma of the ilium, round cell osteosarcoma of the humerus and scapula, and spindle cell osteosarcoma of the superior maxilla.

There remain in Table 1 three cases, a leiomyoma, an angiosarcoma, and a hypernephroma, epitomies of which appear at the end of the paper. The first case (No. 56) was a leiomyoma of the uterus for which hysterectomy was performed. Within a few months the entire pelvis was filled with an inoperable recurrence of hard consistency and irregular outline, apparently involving the bladder. Mixed toxin treatment was instituted. The mass became smaller, softer, more movable, and pain ceased. Treatment was continued with periods of rest for about three years. Three years, eleven months later the patient was in excellent health and local examination showed only slightly more scar tissue than would be expected after an hysterectomy. This was apparently a case of malignant leiomyoma. I have at present under treatment a somewhat similar case referred by Dr. W. J. Mixer. A hysterectomy had been performed for fibroids. Tumors subsequently appeared on the back and paralysis of the legs ensued. Dr. Mixer removed as far as possible a growth involving the vertebrae, complete eradication was impossible. The patient is now able to walk with assistance.

Toxin treatment was instituted immediately after operation and has been continued for two months. Pathological reports: 1. Tumor over sacrum, probably leiomyoma; 2. Tumor on right shoulder, leiomyoma; 3. Specimen removed at operation on spine, spindle cell sarcoma. It is too early to predict the outcome but the course has been so far favorable.

The second case (No. 33) was a thrice recurrent angiosarcoma of the breast. Toxin treatment was instituted when the mass extended laterally from the sternum to the anterior axillary line and from the clavicle above nearly to the costal border below. It was fixed to the chest wall and composed of markedly protuberant nodules and considerably ulcerated. Mixed toxin treatment for eight months caused softening and progressive decrease in size. The mass was then operable and was excised. No pathological report is given but the patient was seen eight years later without evidence of recurrence. This case has been recorded in Group E.

The last case (that of Mr. Cornell of Sheffield, England) was a woman of 37 upon whom a transperitoneal nephrectomy was performed for hypernephroma. In four months toxin treatment was started for a huge recurrence and continued for four and a half months with entire disappearance of the tumor. A year later she was seen in excellent health without evidence of recurrence.

TABLE II.

ANALYSIS OF CASES ACCORDING TO ANATOMICAL SITUATION AND TISSUE OF ORIGIN.

ANALYSIS ACCORDING TO ANATOMICAL SITUATION AND TISSUE OF ORIGIN.

In Table 2 is shown an analysis of cases according to anatomical situation or tissue of origin. It was rather striking in my previous analysis to note that five of six intranasal and nasal accessory sinus cases were apparent cures.

The others fell in Group C, the growth practically disappearing but recurring. Two cases have been added in this series and it is interesting that one is an apparent cure, and the other falls in Group C. These six apparent cures include fibrosarcoma of the septum and ethmoid, giant cell sarcoma of the antrum and superior maxilla, large spindle cell sarcoma of the ethmoid, small round cell sarcoma of the antrum and ethmoid, small round cell sarcoma of the antrum, ethmoid, superior maxilla, posterior septum and nasopharynx, and spindle cell sarcoma of the ethmoid, superior maxilla and frontal sinuses. The case epitomies show the extent of these growths. I must conclude, as previously, that the toxins are apparently of value in sarcomata arising in the nose and accessory sinuses, whether round cell, giant cell, or spindle cell.

Of the Cervical Gland cases it will be noted that there are seven apparent cures of primary growths and four of metastatic extensions from disease of neighboring structures. The latter are indicated in parentheses. This plan has been followed throughout the paper. Only primary growths are considered in this analysis but, believing that the effect of toxins on direct extensions or metastatic growths might be of interest, I have represented such secondary processes in parentheses. The apparent cures of primary sarcoma of the cervical glands are cases 18-24 inclusive, all reported as round or small round cell type, and composing about 10% of the total number of apparent cures. Add to this number four apparent cures of metastatic involvement. It seems fair to regard the toxins worthy of trial in inoperable cases of this type.

The Abdominal Wall cases are seven in number, 5 of spindle cell type, 2 of round cell type, and all apparent cures. Two extensions to the abdominal wall from sarcoma of the ilium were also apparent cures.

The intra-abdominal cases show four apparent cures including three spindle cell and one round cell. These were all inoperable growths involving in one case the ascending colon, small intestine, omentum, and liver border, and in another case the cecum, omentum, and mesentery. In the previous series were recorded seven cases of intra-abdominal sarcoma, all failures. These however, were extensions from thigh, true pelvis, or spermatic cord, or metastases from distant tumors. The apparent cures noted in this table were all primary growths. The two apparent cures recorded in parentheses were spindle cell sarcomata of the abdominal wall involving the bladder.

Of the Bone cases (not giant cell) thirteen apparent cures are recorded; five spindle cell, five round cell, and three mixed cell. The bones involved included two cases of the maxilla, two of the vertebrae, two of the ilium, and one each of the radius, humerus, sternum, metatarsal, tibia, femur, and lower jaw. The results of surgical treatment of periosteal sarcoma of the

femur and upper humerus (including hip joint and interseapulo-thoracic amputations) are notoriously poor. An apparent cure of each is here recorded. It need not be stated that sarcoma of the vertebrae often defy surgical cure. Partial operations are necessarily followed by recurrence and subsequently by death. The case epitomies at the end of the paper are, I believe, sufficiently convincing to justify the use of toxins in these inoperable bone cases. The number of apparent cures, furthermore, comprises over 18% of the total number of apparent cures here assembled.

Of the Giant Cell Bone cases the series shows ten apparent cures including three cases with involvement of the vertebrae, two of the superior maxilla, and one each of the sacrum, ilium, inferior maxilla, radius, and femur.

Under heading *Fascia and Muscles* have been assembled all cases originating from these tissues except those specially listed under headings *Chest Wall* and *Abdominal Wall*. There appear five apparent cures of primary growths and two of secondary growths from the spine and metatarsal. Five of the seven are of spindle cell type, including two of the buttock, and one each of the thigh, knee, and calf. The remaining two are growths of the back, both round cell. Cases of sarcomata of the upper extremities appear among the failures in this series but not among the apparent cures.

Skin and Subcutaneous Tissue cases include sarcomata arising from cutaneous and subcutaneous benign growths (pigmented naevi, etc.). The apparent cures include a melanotic sarcoma of the neck, a spindle cell degeneration of a pre-existing benign tumor of the shoulder, and a round cell sarcoma of the lip.

In reviewing both tables the type of growth most benefited is seen to be the round cell, 39% of the total number of apparent cures. Of this type the small round cell responds very much more favorably than the large round cell type. The percentage of apparent cures furnished by other varieties is spindle cell 36, giant cell about 15, and mixed cell about 7. It is seen that primary growths of bone (not giant cell) furnish the greatest number of apparent cures, over 18%, the giant cell cases furnish about 15%, cervical gland cases about 10%, and nose and accessory sinus cases about 8%. It has been stated that the spindle and round cell cases were evenly divided in bone and intranasal and sinus cases. The cervical gland cases are all round cell.

Very striking relief of pain is occasionally observed with the use of toxins. Coley makes particular mention of this in cases 85, 104, 55, and 56, namely, periosteal spindle cell sarcoma of the humerus, giant cell sarcoma of the sternum, round cell sarcoma of the pelvis, and malignant leiomyoma of the pelvis. The most remarkable cases in this respect which I have observed are a spindle cell sarcoma of the pelvis, and a tumor of the upper jaw encroaching on

the mouth, nose and orbit, both kindly referred by Dr. S. J. Mixter. The first case (No. 54) prior to the institution of toxins suffered such agony that doses of $\frac{1}{2}$ to $\frac{3}{4}$ of a grain of morphine were necessary every two or three hours. During the twenty-four hours he would also receive phenacetin, aspirin, codeia, and cannabis indica. Shortly after the treatment was started only occasional small doses of morphia were necessary, some days none at all. The other case although evidently a very vascular sarcoma of the superior maxilla cannot be included in this series because no pathological report was obtained. This man, who had been accustomed to considerable doses of morphia, entirely omitted the drug after the toxins were started.

CONCLUSIONS.

1. From this critical survey it seems fair to conclude that mixed toxins of streptococcus and bacillus prodigiosus (Coley) are of value in certain cases of inoperable sarcoma.

2. The treatment of primary or recurrent inoperable sarcoma with mixed toxins must be intensive. The increment of the dose and the interval between injections requires some experience. This method of treatment is distressing and is never certain. This analysis has been undertaken, therefore, in the hope of ascertaining the types of case which offer reasonable expectation of benefit.

3. The institution of this treatment is unjustifiable in cases in which operative measures of reasonable safety offer possible hope for removal. A frank statement of the nature and the severity of reactions, and the probability of benefit should be made to the patient or some responsible person before the treatment is undertaken.

4. Seventy-three cases after most rigorous criticism have been regarded as apparent cures.

5. The small round cell type apparently offers the greatest expectation of benefit followed closely by the spindle cell type (excluding fibrosarcoma). Only a relatively small number of mixed cell type have been benefited. The use of toxins in cases with multiple melanotic growths does not seem justifiable but their use in single melanotic growths is legitimate.

6. Regarding the tissue of origin the greatest number of apparent cures have occurred in bone sarcomata (exclusive of giant cell cases) over 18% of the total number of apparent cures, with an equal division of round cell and small cell types.

7. Giant cell cases (as defined in the text) furnish about 15% of the total number of apparent cures. The records seem to justify preliminary trials of toxins in carefully chosen cases in which slowly growing tumors have ruptured more or less extensively into the soft parts rather than immediate amputation. With skilful judgment a few limbs have apparently been saved. If such treatment is practiced, the

patient should understand that amputation may ultimately be necessary, and it should not be long deferred in the advent of increased rapidity of growth, repeated hemorrhages, considerable absorption, or superimposed infection.

A small group on account of anatomical situation, viz., extensive involvement of the vertebrae, defy surgical eradication. These, I believe, should be submitted primarily to surgical attack followed immediately by toxin treatment. The records justify this practice.

8. Primary inoperable round cell sarcomata of the cervical glands compose about 10% of apparent cures.

9. Sarcomata arising from fascia and muscle, which have been apparently cured, have been situated in the lower extremity, abdominal wall, and back. They compose about 16% of the total number of apparent cures. Nine of twelve are of spindle cell type.

10. In a small number of cases the toxins produce striking relief of pain.

CASE REPORTS.

These reports are arranged in groups according to anatomical situation or tissue of origin of the growths. Under these various headings the arrangement is: first, apparent cures, followed in order by cases which have been classed in Group E, Group D, Group C, Group B, and Group A. Personal cases are recorded in detail. Other cases appear in abstract. Reference to de-

tailed reports of such cases appears in parenthesis after the case number in this series. Unless otherwise stated the number in parenthesis indicates the case number in Coley's Brussels Address. When the number is preceded by the word Table, it indicates the case number in the table at the end of Coley's Brussels Address.

INTRANASAL AND ACCESSORY SINUSES.

CASE 1. Personal Case. Referred by Dr. Scudder. Twice recurrent round cell sarcoma of antrum, ethmoid, superior maxilla, posterior septum and naso-pharynx. L. P. Italian woman of 32. House records E. S. vol. 676, p. 221; vol. 702, p. 37; vol. 716, p. 159; vol. 722, p. 57.

March 2, 1910. Operation, Dr. Scudder. Ether Resection of right superior maxilla for sarcoma of the antrum. Ethmoid cells curetted out. Frontal sinus not involved. Sphenoidal sinus opened, contained pus, curetted.

Pathological Report by Dr. James Homer Wright. Malignant Lymphoma. "Specimen consists of the greater portion of the right superior maxilla. Tumor mass fills up antrum, involves bony parts of the right side of the nasal cavity, and also appears on the outside of the bone at two points. Tumor consists of whitish translucent, moderately firm, rather homogeneous tissue. Microscopic examination (paraffin section). Tumor chiefly of cells, generally closely packed together, and a relatively small amount of stroma. Masses of cells are like large lymphocyte forms of cells found in lymphadenoid tissue. Some small lymphocytes are present. There are areas of necrosis."

Oct. 20, 1910. Operation. Dr. Scudder. Ether Partial removal of the septum for recurrent sarcoma.

Pathological Report. (1010-69.) Dr. Whitney. Malignant lymphoma. "A few bits of tissue showing on microscopical examination growth of lymphoid cells, in places slightly elongated and spindle-shaped."

May 11, 1911. Moved to operating room. Seen by Dr. Scudder. "Radical operation with enucleation of eye intended, but impossible to pass Crile ether tube on account of obstruction. Piece of growth removed with tube, evidently sarcoma. Process had extended to left side of nose and face. Only hope lay in attack of both sides of face. Deemed inadvisable."

Pathological Report. (Pieces of tissue removed with Crile tube) (115-42) Dr. Whitney. "Round cell sarcoma. Small pieces of tissue from the nostril, showing upon microscopic examination a small round cell tissue with new-formed blood vessels and remains of small glands scattered throughout it."

May 11, 1911. Toxin treatment instituted and continued three weeks. Maximum dose 3 minims. Reactions severe. Patient followed five months outside hospital, then referred to Boston Dispensary for consolidation in right lung. Later treated at Burroughs Place Clinic, at Long Island, and at Middleboro for tuberculosis of lung.

Feb. 28, 1914. Seen at her home. Still thin but of good color, has done her own housework for the past year, and expects to be confined in a few days. Examination through nose and mouth and opening beneath right eye, which exposes whole nasopharyngeal cavity, shows no evidence of recurrence.

March 26, 1914. Normal child born March 5. Mother still well.

Nov. 2, 1914. Operation, Dr. Scudder. A skin flap swung from forehead to cover defect in cheek following operation March 2, 1910. No evidence of recurrence found at plastic operation.

Criticism. A small round cell sarcoma of the nasopharynx, nose, and left side of face after radical attack of right side. Considered inoperable. No evidence of malignant disease 3 years 5 months after toxin treatment. Recorded in Group F.

CASE 2. Personal Case. Referred by Dr. H. A. Barnes. Small round cell sarcoma of antrum and ethmoid. Throat records, vol. xiii, p. 297. L. A. W., male, 55.

Oct. 14, 1910. Admitted to Ward G. For three months difficulty in breathing through nose. For two months epistaxis twice a week lasting one to six hours. For two months frontal headache, especially on the right, and nasal discharge.

Oct. 14, 1910. Operation, Dr. Barnes. Cocaine. Two large pieces of tissue snared from nose followed by profuse hemorrhage. Ether necessary to check bleeding by packing.

Pathological Report. Small round cell sarcoma. "A small piece of tissue showing upon microscopical examination a solid growth of round and slightly elongated cells infiltrating the tissue in all directions."

Nov. 28, 1910. Operation, Dr. Barnes. Ether. One and one-fourth inch incision on right side of the nose. Nasal process chiseled away and sarcomatous tissue exposed. Posterior nasal plug inserted. Mass scooped out with finger. Antrum then opened through canine fossa and found filled with growth, which was scooped and curetted out. The whole naso-antral wall was found to be destroyed. Antrum and right naris packed with gauze.

Dec. 5, 1910. Toxin treatment started and continued five and one-half months (May 23, 1911). Forty-nine injections. Maximum dose 10 minims. Reactions often severe. During this time the appearance of septum became suspicious and a small piece was removed which showed small round cell sarcoma. Toxins continued two and one-half months longer, at which time a note in the throat department states, "Nose clean; everything in fine condition." Patient had gained 25 pounds.

Dec. 12, 1911. (Seven months since toxins discontinued.) My record reads, "looks well, good weight and color. Working as janitor. No symptoms of recurrence. No evidence of same. Seen by Dr. Mosher who finds no evidence of recurrence."

Last seen Dec. 24, 1913 (two years, seven months since toxins discontinued). In excellent health, good weight and color, working steadily as janitor.

Criticism. A small round cell sarcoma of the antrum and ethmoid. Seems quite improbable that curetting eradicated such an infiltrating process, as recurrence showed. Seems fair to attribute apparent cure in part, at least, to toxins. Recorded in Group F.

CASE 3. Personal Case. Referred by Dr. Crosby Greene. Large spindle cell sarcoma of ethmoid and frontal bone. L. E. F., a woman of 46. House No. 180998.

Feb. 12, 1912. Admitted to Ward G with following history: Eight years ago first noticed movable

mass inside the nose, which was partially removed. Recurred one year later. At second operation (Dr. Greene) under ether a considerable quantity of tumor tissue and ethmoidal bone removed with cutting forceps. Pathological report, spindle cell sarcoma. No evidence of recurrence until last year when began to experience frontal headache and frequent epistaxis, and lately dizziness, nausea, and throbbing in head.

Feb. 12, 1912. Operation, Dr. Greene. Ether. Through an incision at side of nose and beneath eye the antrum opened. Its inner wall and middle turbinate removed. Ethmoidal region found filled with vascular growth which was evacuated with curette. A large portion of the right nasal bone was removed and cribiform plate exposed. Brain pulsation visible.

Pathological Report. No. 122-45. Spindle cell sarcoma. "A piece of growth from ethmoid showing upon microscopical examination bundles of large spindle cells interlacing irregularly. Blood vessels in many places with distinct walls."

Treatment with mixed toxins instituted in one week and continued six weeks. Reactions moderate. Maximum dose 4 minims.

Dec. 2, 1913. A letter from Dr. Greene states that one year after operation (Feb., 1913) no subjective or objective evidence of recurrence.

March 6, 1914 (two years since toxins discontinued). A letter from patient states that her health is very good and there is no indication of old trouble.

A letter received from patient May 29, 1914, states she is still in excellent health, two years, two months since treatment discontinued.

Criticism. An extensive infiltrating spindle cell sarcoma. An extensive operation by Dr. Greene. It may be argued that all of the growth was eradicated at operation. This is possible but at the time it did not seem probable. Perhaps this case should be excluded. It has been recorded in Group F.

CASE 4. Personal Case. Referred by Dr. Mosher. M. L., age two. Throat records, vol. xiv, p. 245.

Dec. 3, 1910, admitted to House with history of appearance of sore in the nose accompanied by much discharge and passage of pieces of tissue. The nose appears flattened and one-fourth inch of the anterior end of the septum has disappeared. The exposed septum is much thickened. Tuberculin skin test and Wassermann test negative. December 8, specimen removed for examination.

Pathological Report by Dr. Whitney: fibroma or fibrosarcoma.

Jan. 20, 1911. Operation, Dr. Mosher. Ether. Septum and thickened ethmoidal region removed as far as possible and packed with gauze.

Jan. 24, 1911. Treatment with mixed toxins instituted and continued five months. Reactions slight, rarely severe. Maximum dose three and one-half minims.

Patient has since been seen by me with rhinologist every few months. Now two years, eleven months since toxins discontinued, there is no subjective or objective evidence of recurrence.

Jan. 29, 1915. Patient still free from recurrence. (3 years 9 months since toxins discontinued.)

Dr. Whitney kindly re-examined the sections in March, 1914, and reported, as previously, fibroma or fibrosarcoma.

Criticism. Owing to the pathological report it may be argued that this case should be excluded. It has been included because the process involved not only the septum but extended up into the ethmoid cells. Recorded in Group F.

CASE 5. (Table, Case No. 88.) Case of Dr. J. C. Whitley of St. Louis, Missouri. Sarcoma of superior maxilla, frontal sinuses and ethmoid.

Pathological Report. Spindle cell sarcoma with giant cells. Toxin treatment instituted immediately after an incomplete operation. Maximum dose, 20 minims. Remains of growth sloughed out. Patient in excellent health without signs or symptoms of recurrence two years later. Recorded in Group F.

(To be continued.)

THE STUDY OF DISTURBANCES OF THE STOMACH.

By H. F. HEWES, M.D., BOSTON.

[From the Clinic of the Massachusetts General Hospital.]

(Continued from page 292.)

All physicians are familiar with the fact that stomach symptoms are perhaps the most common, at all events one of the most common, attributes of the human race. In the study of these manifold stomach conditions he must discriminate as far as possible, by his history record and physical examination, and tube examination in the cases not obviously cases of disease outside of the stomach, whether they are real stomach diseases, or part of a general condition, of debility, or nerve instability, or intestinal atony and constipation, and use the x-ray for their study where his judgment decides for it.

A third special method of investigation of much use in connection with the study of stomach cases is the examination of the feces for blood by the chemical blood test.

A constant or frequent blood finding in the feces in cases with symptoms pointing to stomach trouble is good evidence of the existence of ulcer of the stomach, or duodenum, or cancer. In some cases of duodenal ulcer it is our only means of making a definite diagnosis. Of course blood in the feces may come from hemorrhoids, or intestinal lesion, as intestinal cancer, or ulcer, or colitis. And some of these conditions may give apparent stomach symptoms. But often, as stated, this blood finding taken with other factors of the cases is of much value for the diagnosis of a stomach lesion.

This concludes the review of the methods of clinical study which are utilized in the investigation of cases with symptoms suggesting stomach trouble.

The exact method of procedure of clinical examination for diagnosis differs, of course, with individual cases.

It may happen that the first method of study, the record of symptoms as given by the patient, is sufficient for absolute diagnosis, and further investigation by special methods may be deemed unnecessary. This, for example, is the fact in some cases of bleeding ulcer having a clear record of recent vomiting of blood. Or it may be that this record with the record of physical examination gives a definite diagnosis of some disease outside the stomach, as appendicitis or tuberculosis, which may be deemed a sufficient cause of symptoms.

In all other cases, making the majority of cases with stomach symptoms, it is necessary, however, to go further and make at least a tube examination, and often an x-ray examination also. If the tube examination plus the record previously obtained makes a diagnosis, we may stop here. This is the fact in cases showing twelve-hour food stasis, for example. Such a finding means always obstruction of the pylorus, with rare exceptions due to ulcer or cancer, and often the tube examination tells which of the two, ulcer or cancer.

If with the record and tube examination, diagnosis is not clear, we may resort to x-ray examination. This may show definite evidence of disease, when tube examination is merely suggestive, or when it is entirely negative, or it may exactly locate a lesion already diagnosed by the examination.

The following records of cases taken from my own clinical records, will illustrate the method of procedure followed in the study of stomach cases, and the variation in this procedure according to the character of the particular case in hand. Special cases have been selected also to illustrate some of the most important points already reviewed in regard to the value of the various data obtained by the several methods of examination, for drawing conclusions for diagnosis.

CASE 1. R. L., age 30, Aug. 1, 1911. One week ago the patient, who had had no previous dyspepsia, began to have distress in the epigastrium, coming, perhaps one hour after meals and lasting one to two hours—there was raising of gas and sometimes sour regurgitation, but no vomiting. This has continued to the present time.

Yesterday the patient vomited a quart of red blood. The specimen was seen by her physician.

Examination: Patient rather pale. Hemoglobin, 65%. Physical examination otherwise negative. A diagnosis of bleeding ulcer of the stomach was made without further investigation. It was not considered desirable to use the tube and x-ray examination seemed unnecessary. In fact all that the tube could show would be blood, of which we had evidence in the history, and the x-ray examination would very likely show nothing, as is often the case with fresh bleeding ulcers. The feces examined on the first and second days of observation showed a strong positive blood test. This case could have been one of bleeding from esophageal varix but a diagnosis of ulcer seemed reasonable,

without further investigation. The history, including as it did, one positive objective pathological finding, the blood vomited, was sufficient for the time being. The patient was given medical treatment, was apparently cured, and has had no stomach symptoms since, up to December, 1914.

CASE 2. Age 60, May, 1910. Eight months ago the patient began to have a feeling of distress, and fullness, after eating, with gas and belching. This has continued since. Two months ago the patient began to vomit, at first once or twice a week but for the last two weeks almost daily, often twice a day. Some marked pain before vomiting. Vomiting occurs as a rule soon after eating. Of late the amounts vomited have been large, no blood seen. Much loss of weight and strength.

Examination: Patient thin and pale. Hemoglobin, 80%. Physical examination otherwise negative.

Tube examination: Fasting contents, 500 c.c. of thick fluid containing much food. Blood test positive. No free HCl. Test meal contents, no free HCl. Feces showed a positive blood test.

In this case the history was suggestive of a serious stomach trouble, especially the recent history, but it was not, taken alone, absolutely diagnostic of organic disease of the stomach, since we can get such a history in nerve conditions, or in disease elsewhere affecting the stomach. The recent history was strongly suggestive of stasis which means as a rule cancer or ulcer at the pylorus, but a tube examination, at least, was needed to prove the existence of this condition. Also allowing stasis, special examination was needed to discriminate between cancer and ulcer.

The tube examination here did all these things definitely. It proved stasis by the twelve-hour food residue in the fasting contents, and the absence of free HCl in the fasting and test meal contents indicated that the stasis was due to cancer rather than ulcer. The blood finding by tube and feces examination also proved the presence of organic disease.

In this case no x-ray examination was necessary for diagnosis. It might have had some value as showing the extent of the cancer, but was not needed for diagnosis. X-Ray would undoubtedly have given evidence of pyloric obstruction by cancer or ulcer, probably also would have suggested cancer rather than ulcer, if it had been done in place of the tube examination. But tube examination is more feasible ordinarily than x-ray examination and is therefore done first, often, as in this case, avoiding the expense of x-ray examination. Operation upon this case which was necessarily to relieve the stasis, if not for cure, showed cancer at the pylorus.

CASE 3. R. M., age 25. For three years the patient has suffered off and on from dyspepsia. The symptoms consist of distress in the stomach, coming sometimes soon after eating, sometimes long after eating. Sometimes there is real pain. Sometimes the patient induces vomiting for relief of distress. There is no spontaneous vomiting. No history of

blood at any time. If the patient is very careful she may be comfortable without much dyspepsia for months, but she has some symptoms a good part of the year.

Examination: Patient thin and very pale. Hemoglobin, 70%. Physical examination otherwise negative save for soreness and tenderness over the epigastrium.

Tube examination: Fasting contents 40 c.c. of fluid, no food, no blood. Free HCl present. Sediment shows large number of epithelial cells. Test meal contents, free HCl, 0.18%.

X-ray examination shows an irregular projection in lesser curvature, with check of peristalsis at this point, and incisura in opposite wall, peristalsis vigorous above and below area. No 6-hour residue. Sphincter and cap normal. Feces examination negative.

Here the history was suggestive of chronic stomach trouble, but, alone, justified no positive diagnosis of ulcer or cancer. The tube finding was slightly abnormal in quantity and sediment finding of fasting contents, and in high acid content of test meal contents, but did not justify a positive diagnosis of organic stomach trouble. It showed simply a hyperacidity which may mean ulcer or may not.

It was necessary here to resort to x-ray examination. This method gave a positive finding suggestive of penetrating ulcer of the lesser curvature. This finding together with the history of long continued stomach symptoms, justified a diagnosis of ulcer. Operation showed an old perforating ulcer of the lesser curvature.

In this case the x-ray finding was the really important factor for diagnosis.

CASE 4. E. S., age 65. About four months ago the patient began to have fullness after eating and eructations of gas. Was more comfortable when he ate little. No record of previous stomach symptoms. This has continued and symptoms are now more marked but never very bad. No vomiting. Loss of 20 lbs. in six months. Patient feels weak and appetite very poor.

Examination: Hemoglobin, 60%. Physical examination otherwise negative.

Tube examination: Fasting contents, 20 c.c. of dark colored fluid, no food. Marked positive blood test, no free HCl. Sediment contained many broken down cells. Test meal contents. No free HCl.

X-Ray examination: Some irregularity of outline of stomach in lesser curvature. Peristalsis slightly sluggish. No 6-hour residue, sphincter and cap normal.

Feces examination showed positive blood test.

In this case the history was no way suggestive of serious stomach trouble as far as the record of symptoms of stomach trouble went. There were the symptoms which are frequently seen in cases of debility, nerve conditions, ptosis, that is, in conditions other than organic stomach disease. The only suggestive point was the persistence, and the record of loss of weight and strength. The tube finding was very suggestive of cancer of the stomach, the presence of blood and the ab-

sence of free HCl, together with the blood finding in the feces, if such findings are made on two or more separate occasions, giving us fairly positive evidence for diagnosis of cancer. An x-ray examination was desirable for possible confirmation of diagnosis made by tube finding. X-ray finding was suggestive of organic lesion of the stomach, either cancer or ulcer at the lesser curvature. The x-ray finding here was not as conclusive for diagnosis as the tube finding. If we had had the x-ray record alone we could hardly have made a positive diagnosis as the abnormality found was so slight that accident or some extraneous influence acting on the stomach could have given it, but taken with the tube finding, the x-ray finding was important.

With this evidence, a second tube examination and a second feces examination were made. Tube finding No. 2: fasting contents, 25 c. c. of reddish blood-tinged fluid. Some fresh blood was present. Feces examination No. 2 gave a positive blood test. With this record of a positive blood finding in stomach contents on two occasions, and a positive feces blood finding in two instances, together with the absence of free HCl in the test meal contents, a positive diagnosis of cancer of the stomach was made. With the x-ray evidence the cancer was located in the lesser curvature. Operation showed cancer on the lesser curvature.

In this case we needed the evidence of all methods of investigation, the most conclusive evidence being obtained by tube. I call attention to the short history of symptoms, with steady persistence after the start, in a case of fairly advanced cancer. This is not unusual.

CASE 5. O. T., age 24. Four weeks ago the patient began to notice occasional spells of pain located to the right of the navel. The pain came at any time, after a meal, or when empty. It sometimes lasted an hour or two, sometimes 15 minutes. With it has been associated some belching of gas and stomach unrest. No vomiting. This has continued off and on to the present time. In this period the patient has had several spells of weakness and vertigo when he felt as if he was going to faint. He has grown weaker and has grown pale. Bowels regular.

Examination: Hemoglobin, 70%. Physical examination otherwise negative. No tender spots in abdomen.

Tube examination: Fasting contents, 30 c.c. of fluid. No blood test. Free HCl present. Test meal contents. Free HCl, 0.18%.

X-ray examination. Outline of stomach and duodenum normal, good sphincter and cap. Peristalsis normal.

Feces examination repeated twice always shows a blood test on a meat free diet.

Diagnosis: Bleeding in the intestinal tract, probably due to duodenal ulcer. The patient was treated medically and improved. Two months later he had another spell of weakness and blood reappeared in the feces. Operation showed a bleeding duodenal ulcer.

In this case the history was one which could

go with any simple indigestion, with an appendix, a gall bladder, etc. The only really suggestive sign was the spells of faintness. Stomach examination and x-ray examination were negative. The feces examination made the diagnosis. If we had depended upon the x-ray alone in this case the disease would not have been discovered.

CASE 6. M. L. Age 40. For two years off and on the patient has been troubled with indigestion. The symptoms are nausea and distress located in the pit of stomach, sometimes pain across the abdomen in the region of the navel. The distress is apt to come two or more hours after a meal, but may come at other times. Upon two occasions there has been vomiting with the pain. He has had about five spells in two years. Between spells he may be free from trouble or have mild dyspepsia. Bowels are constipated. He uses laxatives frequently. This spell began a week ago. He has a dull pain much of the time above the navel, and nausea. He vomited once four days ago. No blood seen.

Examination: Hemoglobin, 100%. Temperature, 99.8. Pulse, 86. White count, 15,600. Marked tenderness in the right iliac fossa. No actual spasm. A diagnosis of appendicitis was made. Here the symptoms were located by the patient in the stomach. The history could go with organic stomach trouble. As general examination however located a definite disease outside of the stomach as a cause of symptoms, and no special examination by tube or x-ray was necessary. Appendicitis was found at operation.

Note that the history in this case, of intermittent attacks of stomach trouble over a long period of time, is not unlike that found frequently in cases of duodenal ulcer.

CASE 7. R. P. Age 28. For two years the patient has been subject to spells of stomach trouble, with symptoms of distress, often acute pain, coming two hours or more after eating and relieved by food. There is much gas, and heartburn, sometimes pyrosis, actual regurgitation of acid fluid. Occasionally with bad pain there has been vomiting. No blood ever seen. The vomitus has consisted of clear watery fluid without food. There have been perhaps three spells a year lasting for three weeks to two months, with periods between of complete freedom from symptoms.

Examination: Hemoglobin, 100%. Physical examination negative.

Tube examination: Fasting contents, 80 c.c. of clear fluids containing free HCl. No blood, no food. Sediment normal. Test meal contents: Free HCl, 0.26%, i.e. hyperacidity. Feces examination, negative.

X-ray examination: Outline of stomach and duodenum normal. Peristalsis normal. No residue.

The history of this case suggests hypersecretion or hyperacidity. It could be that of a duodenal ulcer of which hypersecretion is often an associate, or a gastric ulcer, or a simple hyperacidity, or it could have been a gall bladder or neurosis without actual hyperacidity. I have seen such histories with a normal acid content or even a low one. The tube examination proved

the existence of hypersecretion and hyperacidity but it proved nothing as to whether it was a simple hyperacidity or a hypersecretion secondary to ulcer.

X-Ray examination was necessary for further light. The x-ray examination showed a normal stomach and duodenal outline and normal, though active, peristalsis. As a result of the full examination a diagnosis of hypersecretion was made. Ulcer cannot of course be absolutely ruled out by a negative x-ray in such a case, but with a clear tube finding of hypersecretion accounting for symptoms by the discovery of a well-recognized stomach disease, a negative x-ray certainly leaves this diagnosis established for the time. As a matter of fact, this case was operated upon through the advice of a surgeon in spite of the examination, and the stomach opened. No evidence of ulcer was found. I have seen many cases with an exactly similar history to this case and similar findings by tube, give an x-ray finding suggestive of duodenal ulcer, where operation has shown chronic duodenal ulcer. This case gave the symptom complex regarded by Monagan as diagnostic of duodenal ulcer.

CASE 8. R. I. Age 50. For 15 years the patient has suffered off and on from attacks of stomach trouble consisted of distress, sometimes soon after food, sometimes two hours or more after eating, gas, and bloating. Vomiting was rare in the early days, but of late has been frequent. The trouble came by spells with long intervals of freedom from symptoms. About six months ago a spell began which has continued ever since. Recently vomiting has occurred daily often after each meal. Amount of vomitus sometimes large. Vomitus occasionally of dark color. There has been much loss of weight recently.

Examination: Hemoglobin, 75%. Patient very thin. Physical examination otherwise negative.

Tube examination: Fasting contents amount, 1000 c.c., much food present. Blood test faintly positive. Free HCl present. Test meal contents. Free HCl, 0.11%, i.e. normal acidity. Feces examination, blood test positive.

X-ray examination: In antrum and at pylorus an area of absent peristalsis, with irregular outline to shadow, sphincter absent, duodenal cap not well seen. Peristalsis above lesion normal. Large 9-hour bismuth residue.

In this case the history with its duration and record of intermittent attacks suggested chronic ulcer, finally contracting and closing the pylorus as indicated by the advent of persistent vomiting. The tube examination gave absolute evidence of stasis, that is, either cancer or ulcer at the pylorus, but as free HCl was present did not discriminate between cancer and ulcer, as in Case 2, where the absent free HCl favored cancer.

The x-ray examination was made to get evidence, if possible, for discrimination. The x-ray picture here though compatible with ulcer was more suggestive of cancer, with the irregular

character of the shadow and the absence of vigorous peristalsis above the pylorus. Ulcer usually has deep and vigorous peristalsis. Cancer was found at operation.

The long history and tube examination together really favored ulcer, though one factor of the tube examination, the presence of blood, together with the blood finding in the feces was more suggestive of cancer, as constant bleeding is much more common with cancer than with chronic ulcer. The x-ray here turned the tide of diagnosis to cancer. Possibly this was a case of cancer developing on an old ulcer which would explain the combined picture, the long history of trouble, with the actual presence of cancer. One may say that an x-ray examination was not absolutely necessary in this case as the tube finding showed definitely that either cancer or ulcer at the pylorus was present and therefore that operation was necessary. Actual identification of the nature of the lesion could be made by operation better than by x-ray, but it is useful to know as much as possible about the case before operating even when operation is assured. Sometimes an x-ray indicates that cancer involvement of the stomach is so extended that operation is useless, and saves this step.

CASE 9 M. L., age 30. For two years the patient has had spells of stomach trouble consisting of distress and fullness, and raising of gas soon after eating. Occasionally there has been vomiting for periods of a day or two. The patient drinks a good deal of liquor and occasionally goes on sprees. The stomach trouble is especially bad after a spree. The weight is about 20 lbs. below his best weight. Examination: Hemoglobin, 95%. Physical examination otherwise negative.

Tube examination: Fasting contents, 60 c.c. of thick mucous fluid pouring like mucilage. No food, no blood, no free HCl. Sediment contains many epithelial cells. Test meal contents: No free HCl. Total acidity, 0.07%. Feces examination negative.

(To be continued.)

Reports of Societies.

CLINICAL CONFERENCE OF THE NEUROLOGICAL INSTITUTE, NEW YORK.

REGULAR MEETING, JAN. 21, 1915. DR. J. RAMSAY-HUNT IN THE CHAIR.

PLURIGLANDULAR INSUFFICIENCY OF SCLERODERMIC TYPE.

DR. WALTER TIMME presented a woman fifty-five years of age, unmarried, who entered the Neurological Institute in the service of the third division on January 5, 1915, complaining of general nervousness, weakness, inability to stand or walk, and numbness and tingling of the extremities. This condition had been progressing for one and a half years, and with some slight exceptions, had been

getting worse during this entire time. At the onset she first felt a numbness in her hands, and began to be clumsy in their use. She then noticed a gradually increasing weakness in her hands and arms so that she was unable to use a spade in the garden. Later, she was unable to get up from a chair or get out of a hammock. She had cramps in the calf muscles at night and some muscular pains in the thighs and legs in trying to get about. In the fall of 1913 she noticed a stiffness of the neck with pain which lasted until the spring of 1914, accompanied with difficulty in swallowing and with some inability to open her mouth as far as previously. The joints were never painful or swollen. Gradually the motion of the different members became more and more limited and she became bedridden and extremely helpless. During this time she had several falls in trying to get about and undertook osteopathic treatment for the relief of her condition with no effect. There has been some improvement in her arms, but her legs have become progressively worse. Her menstruation ceased two years ago. Her previous history gives the usual diseases of childhood. Eight years ago she had severe pain in the left elbow which was treated by osteopathy and five years ago she had a right sciatica. Syphilis is denied, there are no drug addictions, her habits are good and heredity negative. Her neurologic status upon entrance is as follows:

The patient is fairly well nourished, but presents a picture of trophic disturbances. There is some cyanosis of the extremities, her skin is dry and scaly where it is not glossy, the hair dry and lusterless, and there is a symmetrically disposed pustular eruption on the face. Upon the upper chest and neck there is an area of brownish pigmentation. In various parts of the body there are areas of induration in the skin without discoloration, and also below the skin. These are chiefly in the thighs and lower legs. The skin of the face is dry and drawn, so that it presents a mask-like appearance and offers some opposition to the full opening of the mouth. She says that there is some difficulty in opening the eyes wide. Her pulse rate is 110 and her blood pressure 160. The muscular system is practically everywhere involved atrophically. There is atrophy of the arms, forearm, and largely of the hand muscles, both flexors and extensors, together with contractures; so that she cannot extend the forearm from the arm or the hand from the forearm. In the legs and thighs similar atrophies are present, most marked in the lower legs where the calf muscles and the peronei are involved. She can lift the knees in bed only for a short distance, perhaps a foot or so, and can only slightly abduct them. She cannot sit up unassisted nor can she stand. There is some slight facial weakness on the right side, and some slight difference in the palpebral fissures. There is no myokymia, no tremor; her coördination is good.

The knee jerks upon entrance were absent, but can now occasionally be elicited. There is no Babinski, no clonus. The other reflexes are present and equal. The right pupil is slightly greater than the left but both react equally well to light and accommodation. There are no sensory changes excepting perhaps some slight diminution over the indurated areas. There is no loss of sphincteric control. She has a chronic constipation. The thyroid is slightly enlarged but soft. Emotional control was diminished, so that she would cry at being assisted

to a sitting position for fear of falling; she is irritable, finding fault with her room-mate and with the nurses without sufficient cause. X-ray examination of the left elbow joint is negative, though there is a suspicion of rarefaction in the bony structures. Electric examination of the muscles showed no R. D.; urine, blood and Wassermann are all negative.

So that we have before us a patient in the prime of life, giving evidence of a profound change in many of the tissues of a character that causes a perversion of their functional activity. The onset is concomitant with the beginning of the involutional period of life and with the cessation of menstruation. If we take the symptoms in groups we can readily see a correspondence in them with those due to defective function of various internal glandular organs—the scaly, dry skin to hypothyroidism, the pigmentation to adrenal insufficiency, the acroparesthesiae and cyanosis of the extremities to a combination of ovarian and chromaffin insufficiency. Furthermore, many of the clinical evidences seem to point to entities of which in the past we have seen examples. Thus, to mention two of the more striking ones, dystrophia muscularum progressiva and scleroderma. The patient might, with some justice, be placed in this latter class. She has the sclerodermic condition “en plaques,” the mask-like face, the indurated skin and underlying masses, the atrophies and succeeding contractures and disturbances of motility, the falling out of the hair, the pigmentation, and the erythromelalgia. She has also some of the features of the ordinary muscular atrophy with the wasting of the large thigh muscles and the gradual involvement of other groups. The deep reflexes are returning, any dysphagia she might have had, had disappeared; and there is no fibrillary twitching. The age of onset is rather against this view, also the wasting of the intrinsic hand muscles. A disturbance of the internal secretions may have for its results many of the symptoms common to these disorders. Indeed Cassirer, Ballet and Delhelm and Notthaft have observed cases of progressive muscular dystrophy, scleroderma and Basedow's Disease seemingly combined in one patient, and have come to the conclusion that this incidence of all three had as a basis, a disturbance of the internal secretions. Cassirer goes even further. The disturbance of these secretions is due, according to him, and I agree thoroughly in his views, to a perversion of the function of the vegetative or autonomic nervous system. Indeed he goes to the extreme point of declaring that no one single ductless gland can be alone in its perversion, but must of necessity drag every other one into the arena; so that the various types of the tropho-neuroses assume the characteristics of the condition due to the abnormal activity of the most affected gland. If we examine these clinical types closely we will not fail to find evidences of other glandular disturbances also. And for this reason have we the nuances through which imperceptibly one disease merges into the other, as one or the other internal secretions controls the situation. In the present case, the difficulty probably began in the ovarian involution. The usual compensation for this condition is in an increase of suprarenal capsule secretion which is inhibitory to the suprarenal secretion itself. If this compensation fails, then an increased adrenal content results, with corresponding effect upon the thyroid and so a very complex picture pre-

sents itself. The reason for the assumption of an autonomic basis for this interactivity is, that after section of various of the sympathetic nerves such as the splanchnic, no complementary action results; and further, that autonomic stimulation will produce changes in the internal secretions. This patient has been for less than three weeks on ovarian extract and thyroid, and she is beginning to improve. Her pustular eruption is better, the pigmentation is less intense and she moves her arms and legs more freely than before. How far she will improve time alone can tell.

A CASE OF SUSPECTED FRONTAL NEOPLASM.

DR J. W. STEPHENSON presented from the second division, a man 52 years of age who denies alcoholism, venereal disease, or other previous history of significance. No lead line on the gums. He was first seen on the ninth of January, 1915, his chief complaint being that of frontal headaches of at least six months' duration. He was mildly confused and in consequence of this confusion a detailed account of his immediate history was impossible. However, he volunteered the information that "he could not see quite so well." There was apparently general lassitude and yawning was conspicuous. Examination revealed a man of small but firm stature, confused, answering questions only in monosyllables with a husky voice. His station was unsteady, falling first to one side, then the other, gait was slow and deliberate. There was no apparent ataxia, nor could any tremors be elicited. The knee jerks were elicited only upon reinforcement, the ankle jerks were present and equal, the plantar responses were flexor, there was no clonus. The right epigastric reflex responded more promptly than the left, the abdominals were present but inactive. The eye mobility was good, there was no nystagmus. No diplopia. The pupils were irregular in outline but reacted to light, coming down slowly. Thoracic and abdominal cavities negative. No tenderness could be elicited over the skull nor was there any difference in the percussion note.

Patient has now been under observation for 13 days during which there has been a slow but steady progression of the mental confusion, until it is now practically impossible to get any coöperation from the patient. However he does volunteer the information that his headaches are less severe in a recumbent posture. Analgesics have been used without relief. Patient is now incontinent and uncleanly.

On January 20, physical findings were as follows: The knee jerks which were previously obtained only on reinforcement are now active, and there is a definite Babinski response on the left side, questionable on the right. The epigastric reflexes are not elicited. Pupils very slow. His confusion is decidedly more pronounced. Temperature has ranged between 98° and 99.5°, pulse between 68 and 104, the average being 88; respiration between 16 and 24, average 20; blood pressure between 135 and 150. Blood, urine and feces negative. The serum Wassermann is negative. Spinal-fluid; Wassermann is negative, three cells, considerable excess of globulin, Fehlings reduced. The eye report by Dr. Holden is as follows: "Disc outline slightly blurred, veins over-filled suggestive of beginning papilloedema." In this connection Dr. Stephenson mentions that the observations made by him disclosed a change in the condition of the fundi after lumbar

puncture; the margins of the discs being decidedly more distinct the day after the puncture. Four days after the puncture the disc showed practically the same findings as before the puncture.

I should have mentioned that the patient has had lots of trouble and worry, his wife being alcoholic, and for a long while the headaches were assumed to have been of a functional nature. There has been no vomiting but occasional nausea has been experienced.

Three possible diagnoses have been considered in this case, namely frontal neoplasm, advanced paresis and manic stupor, the latter of which could be eliminated by the presence of the Babinski phenomenon, the nature of the pupillary reflex and the condition of the discs. Advanced paresis is not an impossibility, particularly inasmuch as the ophthalmologist is not convinced that there is an actual beginning choked disc, but Dr. Stephenson considers that the changes observed in the discs before and after lumbar puncture are of great significance; also the globulin reaction was decidedly pronounced and not unlike that which is frequently observed in compressions due to spinal or cerebral neoplasm. The negative Wassermann reaction also militates against the diagnosis of paresis. There is no distinct speech defect though there was a peculiar huskiness of his voice. Test phrases were well performed when coöperation could be obtained. It is a well known fact that frontal neoplasm may exist for a long period of time without developing choked disc.

SYPHILITIC HEMIPLEGIA IN A CHILD AGED FIVE.

DR. T. J. KEYSER presented from the first division a little girl with left sided hemiplegia.

The patient was brought to the Hospital by her father January 16, 1915, complaining of headache, pain in the eyes, vomiting and paralysis of the left arm and leg. The father is being treated at present for pulmonary tuberculosis. He denies ever having had a chancre and shows no evidence of syphilis. The mother and two brothers are living and well. The patient has always been a bright, healthy child.

Four weeks ago (December 18th) the patient complained of pain in the left side of the neck. There was moderate enlargement of the glands of the neck on the left side. In a few days the pain and swelling disappeared entirely.

Three weeks ago (December 25th) she complained of general headache and pain in the eyes. These symptoms have been present almost constantly since, although less severe during the past week. Since the 25th she vomited several times each day. The vomiting occurred suddenly without nausea and was projectile in character.

One week ago (January 9th) it was noticed that the patient could not use the left hand as well as usual. This weakness gradually progressed and extended so that in three days there was complete paralysis of the left leg and arm. There is no history of convulsive attacks or mental symptoms. The temperature has been taken two or three times a day by the father and was normal throughout except on one occasion when it was 99.2°.

The patient is a bright, intelligent child, showing no evidence whatever of mental symptoms. She is well nourished and normally developed. There are no signs at all of congenital syphilis, or tuberculosis of the lungs, bones, etc. The left arm and leg are completely paralyzed. There is a moderate but distinct weakness of the left facial muscles of the

supranuclear type. Otherwise the cranial nerves show no involvement whatever. The deep reflexes are all present, equal and normally active. The abdominal and epigastric reflexes are absent on the left side. Babinski sign is present and Hoffman's is at times obtained on the left side. The electrical reactions are normal and there is no stereognosis. The pupils are equal regular and react promptly. The fundi are normal and there is no restriction of the visual fields.

The temperature varies from 98° to 100°, usually being higher in the afternoon or evening. The pulse rate varies from 96-128. The blood examination shows 16,000 W. B. C. of which 79% are polymorphs. The urine is normal. Von Pirquet's cutaneous reaction negative. The cerebral spinal fluid shows 140 cells to the c. m., of which 132 are small lymphocytes. Unfortunately the Wassermann test was not done on the c. s. fluid. The serum Wassermann was positive at the Neurological Institute. A subsequent Wassermann test by the Board of Health was also strongly positive. The history of the headache and vomiting followed by the development of a hemiplegia of the cerebral type are indicative of a brain lesion. The tubercle bacillus is a possible etiological factor, indicated by the pulmonary tuberculosis of the father, the masses of lymphocytes in the spinal fluid, and the moderate evening elevation of the temperature. However, the positive Wassermann reaction together with a pleocytosis of the spinal fluid are in favor of syphilis as the probable etiological factor, in spite of the absence of all other clinical evidence of this disease. This diagnosis was later corroborated by a prompt response to antisyphilitic treatment.

Book Reviews.

Fever—Its Thermotaxis and Metabolism. By ISAAC OTT, A.M., M.D. New York: Paul B. Hoeber, 1914.

The contents of this book represent three lectures, delivered before medical students. In these three lectures the author discusses fully the various aspects of fever, especially from the experimental and physiologic point of view. Ott himself has made notable researches in this subject. The work is a very complete resumé and is not at all elementary, as might be assumed from the fact that the lectures were delivered before medical students.

Practical Therapeutics. With Especial Reference to the Application of Remedial Measures to Disease and Their Employment upon a Rational Basis. By HOBART AMORY HARE, M.D., B.Sc., Professor of Therapeutics, Materia Medica and Diagnosis in the Jefferson Medical College of Philadelphia. New (15th) edition, thoroughly revised and rewritten. Octavo, 998 pages, with 144 engravings and

7 plates. Philadelphia and New York: Lea and Febiger. 1914.

The fifteenth edition of this book appears in form similar to its predecessors, although, as has been the custom of its author, the text has been liberally revised to meet the changing therapeutic outlook. In this edition Dr. Hare has had the benefit of the expert knowledge of Dr. George E. deSchweinitz, Dr. Edward Martin and Dr. Barton C. Hirst in revising the sections dealing with diseases of the eye; with antiseptics; with venereal disease; and with diseases of the puerperal state respectively. In general, the volume is again decidedly to be recommended as an extremely convenient and practical treatise on therapeutics in the broad sense.

On Dreams. By PROF. DR. SIGMUND FREUD. Only authorized English translation by M. D. Eder, from the second German edition. New York: Rebman Company. 1914.

This little book is not a translation of Prof. Freud's larger work, "Traumdeutung," but a brief popular account of the more essential points of his theory of dreams. A footnote on page 104, in which the translator says "the words from 'and' to 'channels' in the next sentence is a short summary of the passage in the original. As this book will be read by other than professional people the passage has not been translated, in deference to English opinion," shows that the work has been modified for popular reading, and indicates that state of mind of the public which forced Havelock Ellis to publish many of his strictly scientific studies of sexual problems in a foreign tongue.

Lead Poisoning. By SIR THOMAS OLIVER, M.A., M.D., M.R.C.P. New York: Paul B. Hoeber. 1914.

Sir Thomas Oliver has compressed into a small book of a little over 200 pages much information concerning lead poisoning. As is well known, he has for many years been interested in industrial diseases and the dangerous trades, in fact, long before there was any popular concern with the subject, and it is not too much to say that he is largely responsible for the increasing public interest in them. Lead poisoning is one of the most important and one of the most widespread of all the industrial diseases. The author discusses the sources of lead poisoning in the various trades, the clinical features and treatment, both preventive and curative. In an appendix are given the factory and workshop orders of the English Government. It is an important but authoritative monograph, based largely upon the writer's experience and researches.

THE BOSTON Medical and Surgical Journal

An independently owned Journal of Medicine and Surgery, published weekly, under the direction of the Editors and an Advisory Committee, by the BOSTON MEDICAL AND SURGICAL JOURNAL SOCIETY, INC.

THE CLASSIFICATION AND DIAGNOSIS OF DIARRHEA IN BOTTLE-FED INFANTS.

By reason of their commonness the diarrheas of infancy constitute a subject of perennial interest, and it is highly desirable that the general practitioner should, as far as possible, be able to recognize the different varieties. All the forms are naturally more frequent in summer than in the other seasons, but all may be met with at any time of the year. The two great classes are intestinal indigestion and infectious diarrhea; and Dr. Roger H. Dennett, adjunct professor of diseases of children in the New York Post-Graduate Medical School, in a recent paper on this subject, places in a third class the miscellaneous varieties, among which are included cholera infantum (in which no bacterial micro-organism has as yet been isolated as its direct cause), Finkelstein's sugar intoxication, strychnine, diarrhea from the continued daily use of cathartics, and mechanical diarrhea due

to the ingestion of some specific unfit article of food.

Dr. John Lovett Morse gave in the *American Journal of the Medical Sciences* for January an admirable exposition of the various forms of infectious diarrhea, and he divides the micro-organisms which are its primary cause into three main classes: the dysentery bacillus in all its forms, the gas bacillus and similar organisms, and thirdly, other organisms, of which the most important are streptococci, the colon bacillus, and the pyocyaneus. It is impossible to determine from the symptoms what form of organism is the cause of the disease, and there is nothing about the stools which will aid in the differentiation except, in rare instances, the peculiar green color caused by the *Bacillus pyocyaneus*, and also in cases where the streptococcus is the cause. In the former instance the green color will disappear on the addition of nitric acid, and in the latter the streptococcus, which is usually present in large numbers, can be easily recognized by the microscope.

Morse describes a simple method by which the presence or absence of the gas bacillus may be determined in from eighteen to twenty-four hours, but very properly adds the caution that in interpreting the results of the test it should be borne in mind that the presence of a few gas bacilli does not necessarily prove that they are the cause of the disease. While it is not usually difficult to differentiate between the two, the only condition with which a typical case of infectious diarrhea is likely to be confused is intussusception, although when the temperature is high and the symptoms of cerebral irritation are marked and develop before the appearance of the characteristic stools of mucus and blood, the affection may be mistaken for some form of meningitis. Here, if from the symptoms and physical signs the diagnosis is not plain, a lumbar puncture will settle it at once. In mild cases of infectious diarrhea, however, it is not infrequently difficult, if not impossible, to distinguish between this and indigestion with fermentation, and in the diagnosis the most important single symptom is no doubt the temperature curve; for while in indigestion with fermentation the elevation of temperature is either very slight or high but of short duration, in infectious diarrhea, although usually not very high, it is constant and continuous. In many instances a positive diagnosis can be made only by means of a bacteriological

examination of the stools, and as regards the presence or absence of dysentery bacilli, there is unfortunately no method for determining this which does not require special media and a fairly well-equipped laboratory. Infectious diarrhea in infancy is always a serious disease, and the prognosis should, therefore, always be a guarded one.

It can readily be understood how the two forms, infectious diarrhea and intestinal indigestion, may overlap each other, as a baby with any form of indigestion is naturally more susceptible to an infection. Intestinal indigestion however, constitutes by far the largest class of infantile diarrheas, and it is met with more constantly at all seasons than the other, which is more often seen in hot weather. The subdivisions under intestinal indigestion adopted by Dennett are made upon the practical basis of the foods previously administered, though if properly interpreted, he maintains, these have a scientific basis too. Simple intestinal indigestion is caused by feeding mixtures containing more fat, sugar, proteid or starch than the infant is capable of digesting, or by feeding these elements in a form which cannot be digested, and most infants with a diarrhea due to such trouble have a combination of fat, sugar and proteid indigestion which perhaps was originally occasioned by one of these constituents only. Indigestion caused by fat is usually due to the use of top-milks or cream, although such feedings by no means necessarily cause indigestion in all infants. Sugar indigestion is caused, of course, by giving too much sugar, and gruels when given in milk and sugar mixtures, are undoubtedly a contributing factor in the causation of diarrhea in very young infants. Underfeeding includes all those cases in which sufficient food has not been given to make the infant gain, and many of these babies have a more or less severe grade of intestinal indigestion, while their "tolerance" (ability to digest and assimilate food) has been gradually reduced during the time this has lasted. Overfeeding is apt to be easier to treat if it occurs in a well-nourished child. The diagnosis of simple intestinal indigestion is not difficult. The onset is gradual and there is no fever. While the stools may vary greatly in color and consistency their odor is generally normal. There is no blood, unless this should be due to some local condition in rectum or anus, and mucus is practically always present.

The fermentative type of diarrhea is caused

and aggravated by the intestinal bacteria which feed upon carbohydrates, and putrefactive diarrhea by those which feed upon protein, and the former is far more common because of the universal custom of giving a large amount of sugar to bottle-fed infants. It is easy to distinguish either of these from simple indigestion by the fact that a low grade of fever (usually from 99° to 102° F.) is present in the fermentative and putrefactive types. Much more difficulty is found in differentiating between the fermentative and the putrefactive type, a bacteriological examination of the stools not being practicable for the general practitioner. Apart from the stools, there are two main points of distinction. First, the fermentative form almost always occurs in the infant who has been fed a high sugar or starch diet, while the putrefactive is met with in infants who have been given strong milk mixtures with little or no starch in them, or in older children who are fed on a mixed diet. The second means of distinguishing between the two is the therapeutic test. A fermentative diarrhea will respond readily to a mixture made up of one-third milk and two-thirds water, the two being boiled together without sugar. In putrefactive diarrhea this treatment will be of no service, but the condition will yield to a starch diet, consisting of a thick gruel. When employing the therapeutic test Dennett states that it is usually better to give a boiled milk mixture to infants under five or six months and the gruels to those over that age, since younger infants are more liable to fermentative diarrhea and older ones to the putrefactive form. The sour odor of the stools in fermentative diarrhea is very characteristic, and the foul odor of putrefactive diarrhea (resembling that of decayed meat) is also very helpful in the differential diagnosis. Again, the reaction of the stools in fermentative diarrhea is always acid, and the acidity usually occasions inflamed buttocks and chafing, while in putrefactive diarrhea it is always alkaline, and the skin is not apt to be irritated.

CARNIVOROUS AND HERBIVOROUS TYPES IN HUMAN EVOLUTION.

As a leading article in this issue of the JOURNAL we publish the initial paper in an important piece of research by Dr. John Bryant on the carnivorous and herbivorous types in man, and the

possibility and clinical utility of their recognition. It is suggested that humankind may conveniently be classified into these two animal types and that upon the basis of this classification valuable clinical differentiations may be made and practical details of hygiene, diet and medical treatment determined.

Roughly speaking, the herbivorous type is short and rotund, the carnivorous tall and lean. These superficial characteristics are paralleled, according to Dr. Bryant's elaborate tabulation, by corresponding contrasts in nearly every detail of anatomy and physiology. On these contrasts and their combinations are based the various so-called diatheses.

As a matter of fact, apart from the important possible clinical bearing of this classification, such a differentiation of human types seems equally of interest from the evolutionary point of view, since probably both types represent diverse lines of development from lower animal forms. Racially the carnivorous type is the more active, energetic and dominant; the herbivorous type more stable, artistic and contemplative. Each has the advantages and dangers of its characteristics: the herbivorous type tends to survive by virtue of its stability, the carnivorous by its superior energy and versatility. On the whole, it would appear as though in the history of the world, progress has been achieved chiefly by successive carnivorous races, which finally perish, falling victims to their inherent defects, and are replaced by the evolution of new carnivorous types from the herbivorous substratum. Probably the carnivorous type is really the superior, though it encounters peculiar perils in maintaining that superiority, and as a matter of fact it appears, certainly in the majority of American communities, that the carnivorous type predominates. This is evidenced by the rapid evolution, in the second and third generations, of carnivorous types out of immigrants of herbivorous type from European countries. Whether this is solely a result of diet or climate is not wholly clear.

Another aspect of possibly considerable significance in this consideration is that in their origin these somatic types are, to a certain extent, sex types; the fundamental feminine type is herbivorous, the fundamental masculine type is carnivorous. Whether this differentiation originally proceeded from occupation is not certain, but seems definitely likely. The man adapted to the hunt acquired height, strength

and the leanness essential for speed, and thus became carnivorous; the woman, adapted to more sedentary domestic occupations, remained herbivorous. Now perhaps the most striking fact of all is, that in the course of evolution, as these types have tended to intermix between the sexes, the physical type of each sex has tended to approximate a common mean; with the progress of that form of evolution which we call civilization, the masculine type has tended to become more feminine and the feminine type more masculine. This is particularly obvious in the present day and generation to anyone thoughtfully engaged in the practice of medicine. Especially is it notable that the short, rotund, typically feminine type is disappearing before the predominance of women of the tall, slender, more masculine physique. Between the masculinized woman and the feminized man there remain, of course, fundamental skeletal and other differences, but the sex types are not so widely diverse as they probably were in remoter times.

It is, of course, impossible to foresee what may be the ultimate course of reciprocal evolution between the carnivorous and herbivorous types. Ideally it should lead to the evolution of a standard human type, in which, as the sex types approach each other, they should be mutually benefited anatomically, physiologically and intellectually. Probably such an ultimate ideal type would be largely a persistence of the carnivorous form by constant absorption from the herbivorous substratum of its mental and physical merits, without its defects. In the lower animal kingdom the ultimate dominance of the carnivore over the herbivore seems established. Such is the story of the past, as written in the chapters of biology. Such, or somewhat similar, may be expected to be the future story of man as written in the later chapters of human evolution.

OPERATION OF THE HARRISON BILL.

IN an insert in the JOURNAL for February 18 we commented editorially at length on the provisions of the new Harrison drug bill, on its relation to the medical profession, and on the duty of physicians in complying with its provisions. One important statement unintentionally omitted in this comment should be called

to the attention of the profession. It is as follows:—

“While the Federal law requires the prescriber to bear the date and full signature of the prescriber, Article 12 of the Regulation makes it necessary that the prescription should carry the patient's name and address as well.”

The Harrison law went into effect on Monday of this week. On or before Friday of this week, March 5, it is the further duty of every physician, if he has not already done so, to take an inventory of all opium, salts of opium, coca leaves, cocaine, alpha and beta eucaine, and preparations containing the same in his possession. This inventory must be sworn to before a justice of the peace and kept on file subject to inspection, together with the record which the law requires of all administration, dispensation or distribution of these drugs after March 1. The office of the internal revenue service of the United States Treasury Department has furthermore called attention to the following statements with reference to the operation of the Harrison law:—

“That the period for which registration must be made before March 1 is from March 1 to June 30, 1915, both dates inclusive, or one-third of the Government fiscal year.

“That the registration fee for said period is 34 cents.

“That the order blanks required under the provisions of the Act will be obtainable from the Collector at \$1.00 per hundred.

“That the word ‘person’ as used in this Act shall be construed to mean and include a partnership, association, company or corporation as well as a natural person.

“That any person who violates or fails to comply with the requirements of the Act shall on conviction be fined not more than \$2000 or be imprisoned not more than five years, or both, in the discretion of the Court.”

PROMPT USE OF DIPHTHERIA ANTI-TOXIN

THE Boston Board of Health has recently issued to physicians in the city a copy of its resolutions, urging the early use of diphtheria anti-toxin in all cases of proved and suspected diphtheria, without awaiting the result of bacteriologic determination. The text of the resolution is as follows:—

“At a meeting of the Board of Health held this day, the following procedure in the use of anti-toxin in the treatment of diphtheria was approved and is hereby recommended to the physicians of the city:

“That anti-toxin be used at the earliest possible moment in all cases of real and suspected diphtheria, without waiting for the bacteriological examination of cultures.

“It is further recommended to consider all cases of croupy breathing in children, which continue six hours or more, as severe cases of diphtheria, *i.e.* laryngeal diphtheria, regardless of other clinical signs or bacteriological examinations. These cases should be treated with single maximum doses of antitoxin and should be intubated within 24 hours from time of use of anti-toxin, unless marked improvement in breathing is noticed; since single maximum doses as above described are far more efficacious than repeated doses of less potency, and therefore should be given in this way, while the practice of giving repeated injections of smaller doses should be abandoned.”

During the preceding week there were 47 cases and seven deaths of diphtheria in Boston. This is not an unduly large number of cases but the relatively high death-rate affords reason for again emphasizing to physicians the cardinal importance of promptness in the administration of anti-toxin to suspected cases. The Board of Health further wisely urges the administration of an immunizing dose of antitoxin to persons who have been exposed but as yet show no signs of infection.

THE FAILURE OF AN IMPORTANT BILL

IN the issue of the JOURNAL for February 11, we commented editorially on the bill then pending before the General Court providing a maximum fine of \$300 for violation of regulations made by the state department of health. This bill was intended to remedy the important defect in the structure of the act establishing this new department in the failure to provide penalties for such violation. In spite of the fact that this obviously desirable bill was advocated by Dr. McLaughlin, the state health commissioner, Dr. Walter P. Bowers and other distinguished representatives of the medical profession, it was summarily defeated in the Senate on February 23 without division or debate. As a result the state department of health, though given full power to make regulations, has no authority to enforce them by the imposition of suitable penalties.

This action of the legislature is a lamentable example of the political methods whereby good forms are frustrated of much of their benefit by refusing complete authority to those whose ability is entrusted with serious responsibilities and duties.

MEDICAL SCHOOL NUMBER OF THE HARVARD ALUMNI BULLETIN

THE issue of the *Harvard Alumni Bulletin* for February 10, 1915, was published as a Medical School number and contains a large amount of material descriptive of the Harvard Medical School and its various departments of activity. There are special articles on medical education by Dr. Edward H. Bradford; on the laboratories, hospitals, libraries and museums by Dr. John Blake; on the history of the Medical School by Dr. Harold C. Ernst; and on its present activities and future plans by Dr. Bradford. The School for Health Officers and the Cutter Lectures are also described. This issue is of particular interest to physicians in general not only for its description of our largest New England school of medicine but also for its evidence of the progress in medical education and research, which is the peculiar property of no school, but which redounds to the benefit and advancement of the profession and of the public at large.

MEDICAL NOTES

GOOD WEATHER LAST WEEK CAUSES LOW NEW YORK DEATH RATE.—During the past week 197 deaths were reported than in the corresponding week of 1914, the rate falling from 16.52 to 11.11 per 1000 of the population. This is a decrease of 2.4 points, which is equivalent to a relative decrease of 257 deaths. This decrease was undoubtedly due to the favorable weather conditions prevalent during the last week. In measles, scarlet fever, whooping cough and typhoid fever the percentage of decreased mortality ranged from 50 to 75%. The effect of good weather conditions was felt everywhere—diarrheal diseases, organic heart diseases, influenza, bronchitis, pneumonia, tuberculosis, Bright's disease and nephritis, all showed some decrease in the mortality rate. The deaths of extremely young infants, that is, those under one year of age, were 68 fewer in

number than in the corresponding week of 1914. Every age group showed a decreased mortality, but none as much as that of the infants. The deaths of old people, 65 years and over, were 60 fewer in number.

The mortality in the City of New York since January 1, 1915 to date has been 13.95 per 1000 of the population as against a rate of 14.85 during the corresponding period of 1914, a reduction of .9 of a point.

AWARD OF THE VIRCHOW MEDAL.—It is announced that the Rudolph Virchow Medal has been awarded by the Berlin Anthropological Society to Dr. Karl Poldt, emeritus professor of anatomy at the University of Vienna.

GOTCH MEMORIAL FUND.—An item in a recent issue of *Nature* states that the University of Oxford has recently received a fund of £550 as a memorial to Dr. Gotch late Waynesfleet professor of physiology. The income of this fund is to be applied to the annual award of a Gotch memorial prize and to the creation and maintenance of a Gotch Memorial Library in the laboratory of physiology.

THE MELLON INSTITUTE.—The new building of the Mellon Institute of Industrial Research was dedicated at Pittsburgh, Pa., on February 26. The principal address was by Dr. Rossiter W. Raymond. In the evening Professor John J. Abel of Johns Hopkins University delivered the first Mellon lecture under the auspices of the Society for Biological Research on "Experimental and Chemical Studies of the Blood and Their Bearing on Medicine."

CINCINNATI MUNICIPAL HOSPITAL.—The new municipal hospital of the city of Cincinnati, Ohio, recently completed, at an estimated cost of \$4,000,000, was dedicated on February 20, with appropriate exercises. The principal address was by Dr. H. S. Pritchett, chairman of the board of trustees of the Carnegie Foundation.

BUBONIC PLAGUE IN HAVANA.—Report from Washington on February 17 states that the usual methods have been adopted for dealing with the recent outbreak of cases of bubonic plague at Havana. Six additional inspectors have been ordered to be employed by the Public Health Service and an expert freight inspector has been sent from New Orleans to examine all freight cars intended for the United States, which shall be labeled and sealed after his inspection before being loaded on a ferry. All vessels from American ports are to be disinfected prior to departure.

DEDICATION OF THE PENNSYLVANIA DENTAL INSTITUTE.—On February 22, the new building of the Evans Museum and Dental Institute of the University of Pennsylvania was dedicated with appropriate ceremony. The building represents a cost of \$1,000,000 and is the gift of the late Dr. Thomas W. Evans, an American Dentist who died in France in 1897.

EUGENIC LEGISLATION IN VERMONT.—A so-called eugenic marriage bill was passed to its third reading in the House of Representatives in the Vermont Legislature on February 23, requiring physical and mental examination of all applicants for marriage license.

"Applicants for licenses would be required, under the provisions of the bill, to furnish a physician's certificate that they were free from transmissible disease. Town clerks would be forbidden to issue licenses to persons of unsound mind, or to any person who was under the influence of liquor or narcotics.

"Persons seeking to evade the law by getting married in another state and then returning to Vermont to live would have their marriage declared void under one section of the bill."

ASSOCIATION OF AMERICAN MEDICAL COLLEGES.

—The annual convention of the Association of American Medical Colleges was held in Chicago on February 15, 16, and 17. At the closing session Dr. C. L. Barden of Madison, Wisconsin, was elected president for the ensuing year. Resolutions were adopted recommending that general hospitals be forbidden to exclude patients suffering with tuberculosis.

MEDICAL SOCIETY OF THE STATE OF NEW YORK.

—It is announced that the 109th annual meeting of the Medical Society of the State of New York will be held in Buffalo on April 27, 28 and 29.

"Through the coöperation of the military authorities, the meeting will be held in the 65th Regiment Armory—not the old arsenal, now the City Convention Hall. This armory is one of the largest in the country and will afford accommodations for all activities of the meeting, except the annual banquet. A restaurant will be conducted in the building, there will be ample space for commercial and scientific exhibits, and an abundance of halls for general and section meetings. Even an automobile park will be provided on the armory grounds. No one need leave the building except to sleep, unless possibly to attend lectures to the laity, which will be given by prominent visiting physicians and which will probably be held in the Masten Park High School across the street.

"The choice of the armory is fortunate in another sense, as indicating the organization of the State Society as an arm of the state government. On the last night of the meeting, a regimental parade and review by Gen. Gorgas will be held."

AWARD OF THE SPINGARN MEDAL.—The first Spingarn medal has recently been awarded to Dr. Ernest Everett Just at the annual meeting of the National Association for the Advancement of Colored People.

"The Spingarn medal, which is to be awarded annually to the man or woman of African descent and American citizenship who shall have made the highest achievement during the preceding year in any field of elevated or honorable human endeavor, was given to Dr. Just for his work in physiology and in improving the standard of negro medical schools. Dr. Just, who is only 31, was graduated with the highest honors from Dartmouth in 1907, and is now head of the Department of Physiology in the Howard University Medical School. He was born in Charleston, S. C.

NATIONAL COMMITTEE FOR MENTAL HYGIENE.

—The annual meeting of the National Committee for Mental Hygiene was held in New York on February 17. It was announced that several important gifts have been received for carrying on the work of the organization, \$50,000 from Mrs. Elizabeth Milbank Anderson and \$44,500 from Mrs. William K. Vanderbilt. The Rockefeller Foundation has also contributed for a period of years the services of Dr. Thomas W. Salmon, the medical director of the committee. Dr. Salmon's report of the past year's work dealt particularly with the surveys of conditions carried on among the insane in various parts of the country.

"These surveys, it was stated, mark the beginning of a nation-wide study by the national committee. As a part of the survey work, state societies for mental hygiene are to be organized throughout the country.

Already such agencies are at work in seven states and groups in 20 other states are preparing to organize them. It is these state societies which will carry out the plans for betterment, at the same time conducting work for feeble-minded and for the prevention of nervous and mental disorders."

TRANSFER OF NEW YORK QUARANTINE SERVICE.

—Report from New York on February 17 states that the committee on public health of the New York Academy of Medicine has recently forwarded to Governor Whitman a letter urging the transfer of the New York Quarantine Service from local to federal control and enclosing the report of a committee which has made a special study of the advantages that would accrue from the adoption of such a policy.

"The committee points out that the term of the present health officer of the port expires this month and that it would be an appropriate time for the Government to make the move for transferring the work to the Federal Government. The report shows that in 1913 and 1914 it cost \$96,080 and \$91,900 respectively more to maintain the station than the revenue derived from it."

New York and Boston remain the only two large American cities whose quarantine is still under local administration, and in each the transfer to federal control is approved by the majority of the medical profession in the interests of the public health.

PENDING TUBERCULOSIS LEGISLATION.—It is announced by the National Association for the Study and Prevention of Tuberculosis that legislation dealing with the subject is now under consideration in 32 states of the Union.

In 6 states—Alabama, Arizona, California, Iowa, Tennessee and Washington—bills are being considered which call for the reporting and registration of all living cases of tuberculosis. In Alabama, Connecticut, Iowa, Massachusetts, Pennsylvania and the District of Columbia are working for laws which will require that consumptives who refuse to observe sanitary regulations and are a menace to others may be removed and detained in hospitals. In Alabama, Arizona, California, Illinois, Maine and Missouri, legislation permitting the establishment of county or local hospitals for tuberculosis are being discussed, and in California, Illinois, Iowa, Maine, Missouri and New Hampshire state subsidies of \$3 to \$5 per week per patient are being asked for such institutions. A more or less complete reorganization of the state health work is sought in several states, especially Kansas, Michigan, Minnesota, Nebraska, Texas and Arizona. In Indiana and Alabama bills providing for full-time county and city health officers are being considered.

As an aid in furthering these and similar bills, the National Association has issued a pamphlet entitled "Tuberculosis Legislation," which contains a digest of existing laws in this field with comments and comparisons of some of the most important ones."

In Massachusetts a bill authorizing the trustees of the Boston Hospital for Consumptives to increase beds not exceeding 100 in number for tuberculosis patients in Boston until July 1, 1921, has been reported favorably by the legislative committee on public health.

EUROPEAN WAR NOTES.—On Feb. 17 it was reported to the American Committee of the American Ambulance Hospital in Paris that 92% of the wounded patients thus far received in the institution have been returned to duty. The total mortality of 8% is higher than that of other field hospitals since only the graver major cases are sent to the American hospital. During December and January the hospital was occupied to 75% of its capacity. On Feb. 15 it contained a total of 290 cases. The total amount of money received by the hospital from August 1 to Jan. 1 has been approximately \$440,000, of which about \$20,000 was contributed by Americans resident in Europe. During the months of November, December and January the average daily cost of

each patient was only \$1.51, considerably lower than the rate in any New York hospital.

On Feb. 20 ten additional American Red Cross nurses sailed from New York aboard the steamship *Rochambeau*. Nine are detailed to work at Yvetot, France, and one at Paris.

On Feb. 27, the total of the New York Belgian relief fund amounted to \$941,462.74; the American Jewish relief fund to \$494,779.43; and the American Ambulance Hospital fund to \$346,451.00.

On Feb. 28, the total of the New England Belgian relief fund amounted to \$223,569.04; the Massachusetts Red Cross fund to \$110,636.28; the New England Jewish relief fund to \$38,286.57; the Polish relief fund to \$22,824.97; the New England British imperial relief fund to \$21,479.86; and the Boston Russian relief fund to \$10,787.00.

THE MODERN HOSPITAL PURCHASES THE "INTERNATIONAL HOSPITAL RECORD."—*The International Hospital Record*, which has been published for eighteen years, has been purchased by The Modern Hospital Publishing Company of St. Louis and Chicago and will be merged with *The Modern Hospital*, beginning with the March issue. *The Modern Hospital* is a monthly magazine devoted to the building, equipment and management of hospitals, sanatoria, and kindred institutions. Recently it has opened several new departments relating to public health problems, such as "Philanthropy and the Public Health," "Prevention of Tuberculosis," "Dispensary and Out-Patient Work" and "Life Extension." The editorial offices of *The Modern Hospital* are located in Chicago and the publication offices in St. Louis.

BOSTON AND NEW ENGLAND.

WORK OF MAVERICK DISPENSARY.—The recently published annual report of the Maverick Dispensary of East Boston records the work of that institution for the past year. During this period 5,211 patients were treated, an increase of 41% over the previous year. The expenditures for the same period, however, were increased only 4%. The trustees make an urgent appeal for further contributions to aid the organization in its work.

HOSPITAL BEQUESTS.—The will of the late Laura F. Hall of Lexington, Mass., who died on February 14, was filed on February 20 at the East Cambridge Probate Court. It contains bequests of \$2000 each to the New England Hospital for Women and Children and the Boston Floating Hospital.

IN-STRUCTIVE DISTRICT NURSING ASSOCIATION.—The annual meeting of the Boston Instructive District Nursing Association was held on Wednesday evening of last week, Feb. 24. The report of the director, Miss Mary Beard, stated

that through its eight sub-stations the association during the past year has treated 13,112 patients and its nurses have made 123,065 visits. The total expenditure of the association amounted to \$66,000.

TRANSFER OF PARENTAL SCHOOL BUILDINGS.—The buildings and property of the West Roxbury Parental School have been formally transferred to the trustees of the Boston City Hospital. These buildings will first be used for receiving convalescents from the South Department. They are later to be remodeled at an expected cost of \$225,000, to serve as a children's hospital.

BOSTON MILK AND BABY HYGIENE ASSOCIATION.—It is stated by the Boston Milk and Baby Hygiene Association that of the 4097 babies cared for at its milk stations during 1914, over 40% were brought voluntarily by their mothers. Nurses of the Board of Health brought 18½%, physicians 13½%, milk station agencies 13%, district nurses 10%, settlements 2½% and relief agencies 1%.

ST. MONICA'S HOME.—The recently published annual report of St. Monica's Home for sick colored women and children in Roxbury, Mass., records the work and progress of this institution for the year 1914. During this period 48 new patients were admitted and a total of 65 were cared for. The principal item of interest in the report is the announcement of the acquisition by the institution of a four-story brick house adjoining its property. This building will be remodeled and connected with the present home, enabling improved accommodation for attendants and a re-arrangement of the present wards to admit a larger number of patients. For this purpose and the payment of the mortgage on the new property a sum of \$6000 will be required and generous public subscriptions for this amount are earnestly solicited.

FREE PUBLIC HEALTH LECTURES.—On Wednesday of last week, Feb. 24, was given the first of a series of free public health lectures at 6 Marlborough Street, Boston, under the auspices of the committee on public health education of the American Medical Association and the department of public health of the Women's Municipal League of Boston.

The addresses at this first meeting were by Dr. Walter E. Fernald, Dr. George L. Wallace and Messrs. C. C. Carstens and James E. Fee. Dr. Fernald stated that there are 7,000 known feeble-minded persons in this state and that feeble-mindedness is rapidly on the increase throughout the community. Dr. Wallace advocated the appointment of special expert health officers to detect defectives and secure their commitment to state institutions.

The other four lectures will follow on the Wednesdays in March.

MASSACHUSETTS GENERAL HOSPITAL.—The recently published 101st annual report of the Massachusetts General Hospital records the work and progress of that institution for the year 1914. During this period a total of 6712 patients were treated in the wards and 24,957 out-patients made a total of 158,000 visits, 11,000 more than in 1913. The total number of patients in the convalescent home was 681. Particular emphasis is laid on the need of the hospital for a new administration building, a private ward and a nurses' home at Waverley for the McLean Hospital. In speaking of the need of an administration building, the report says:

"The main entrance to the hospital is now at the end of the Bulfinch Building on Blossom street. It is at the extreme end of the great hospital plant, instead of in the middle, where it should be. Patients and their friends and visitors to the hospital must go through the narrow, dark and crowded corridors of the building erected 100 years ago.

"There is no suitable waiting room, no proper reception room. The business offices are much overcrowded. It is impossible to do the work of the hospital administration in the way that we would like to do it with the tools at our command."

Particular attention is also called to the need of hospital accommodation for persons of moderate means who are often less well cared for medically than the really poor. Of these the administrator's report further says:—

"This group in the community must often be ill in their homes, dependent upon physicians who cannot provide the necessary laboratory tests and scientific examinations which are readily available in a general hospital. I appeal to generous benefactors to help this group. I am convinced that the way to do it is to erect a hospital building for them in connection with first-class general hospital."

EPIZOOTIC OF FOOT AND MOUTH DISEASE.—Several new cases of foot and mouth disease have been discovered in various parts of Massachusetts during the past week. Six cases are now known to have occurred at Waltham, Mass. and several in Weston and Watertown. Two hundred infected and exposed cattle have been condemned in these three towns. On Feb. 1 cases were discovered in Lexington and Southboro, and in Lexington over 300 animals have been condemned for slaughter. Both Maine and Vermont have forbidden the shipment of livestock into their territory from Massachusetts until this recurrent epizootic is at an end. On Feb. 20 Dr. Lester H. Howard, commissioner of animal industry, issued a statement announcing that this secondary outbreak is now well under control. This secondary epizootic has assumed considerable proportion, 522 cattle having been infected or exposed in 15 different communities. In the first outbreak 1156 cattle were infected and 32 cities and towns were involved.

"The cities and towns in which the disease has been discovered and which have been quarantined as a result, are Worcester, Springfield, Chicopee, Waltham, Arlington, Watertown, Weston, Lexington, Northboro, Southboro, Holden, New Braintree, Oakham, and South Attleboro. Although the Department of Animal Industries has not placed a state-wide quarantine on cattle, in all of the communities which have been mentioned the commissioner has refused to allow the transportation of any cattle without a permit, which is issued only after an investigation has been made by an agent."

On Feb. 22 several cases of the disease were discovered at Middletown, R. I., where 71 animals were slaughtered. On the same day fresh centres of infection were discovered in Jefferson, Oldham, and Bullitt Counties in Kentucky, where quarantine has been extended and 1000 cattle slaughtered. A circular letter has been issued to the county judges, urging them to call mass meetings and organize vigilance committees to combat the disease. On Feb. 23 the United States Department of Agriculture extended its quarantine over the states of Illinois, Indiana, Iowa, Michigan, New Jersey, New York, Ohio, Pennsylvania and Wisconsin.

One county in Illinois, one in New Jersey, two in New York, two in Pennsylvania, and a portion of one in Iowa were added to the closed area. All of Michigan, with the exception of three counties, recently was placed in a restricted area.

On February 24, in view of the recrudescence and progress of the epizootic of foot and mouth disease in Massachusetts, Governor Walsh issued a formal proclamation to cattle owners in this State warning them of the imminence of a renewed declaration of universal quarantine. The text of this proclamation is as follows:—

"Whereas, the foot and mouth disease still exists among the cattle, sheep and swine of 18 states of the Union, and new cases are constantly developing in different parts of the Commonwealth; and,

"Whereas, it is proven that the contagion may be carried not only by persons and animals, but by all forms of merchandise, and therefore the livestock interests of Massachusetts will continue to be endangered until the disease is entirely eradicated from the country; and,

"Whereas, the further spread of the disease will involve large expenditures of money on the part of the state and may render necessary the destruction of large numbers of cattle, sheep and swine, together perhaps with the inauguration of a state-wide quarantine, to the serious inconvenience and loss of stock owners; and,

"Whereas, if the disease is not eradicated from the state before the season for pasturing cattle arrives, cattle owners will be subjected to additional loss from the necessity of keeping all cattle confined in buildings in the infected areas and of feeding them without resort to summer pastures;

"Now, therefore, I, David I. Walsh, Governor of the Commonwealth, do earnestly urge all stock owners to realize their responsibility in this matter and, accordingly, in their own interest as well as for the public good, to exercise more than ordinary care in looking after the welfare of their animals; for one of the most effective means of preventing the spread of this disease is the maintenance by individuals of a strict quarantine of their own premises.

"I call upon all good citizens to comply strictly with all orders and regulations of the Commonwealth's Department of Animal Industry. The department will gladly furnish stock owners with information regarding the best methods of guarding against the infection and the most effective ways of quarantining their premises."

On February 25 a case of foot and mouth disease was reported at Everett, Mass. The city was quarantined and the exposed herd of twelve cattle was slaughtered.

Miscellany.

SANITARY CONDITIONS AT THE BOSTON IMMIGRATION STATION.

THE recently published report of the United States commissioner general of immigration for the fiscal year ended June 30, 1914, contains some not altogether favorable comment on sanitary conditions at the immigration station on Long Wharf, Boston.

"The medical officer in charge of the station refers in his annual report to the fact that the detention quarters and their appurtenances are kept in a mechanical state of cleanliness that never fails to elicit favorable comment from visitors. But in spite of such efforts, he adds, the partitions and ceilings, which are constructed of matched boards, 'have now finally become hopelessly infested with vermin.' Referring to the dormitories the medical officer speaks of the insanitary conditions and the efforts made to prevent morbidity among the inmates. 'For considerable periods during the past year the number of detained passengers held at the station has averaged over two hundred, and from time to time the limit of sleeping capacity has been practically reached. Catarrhal affections, bronchitis and tonsillitis, or septic sore throats, have been constantly prevalent in spite of the fact that persons showing symptoms of throat trouble are always immediately removed from the station. Slight wounds or scratches received by inmates or immigration employees working about the station almost invariably become infected. During the winter at least one probable case of typhus fever was removed from the station under circumstances pointing to possible infection in the station itself. Twice during the

winter it was deemed advisable to remove all the inmates of the station to the local (municipal) quarantine station and clean them and subject their clothing to steam disinfection. In the meantime the detention quarters themselves were disinfected so far as it is possible to do so.'

'A few months ago a family of detained aliens was reported by one of the surgeons as showing 'in general' no tendency to cleanliness, with the result that their clothing had been found alive with vermin. This has caused numerous complaints on the part of other inmates trying to keep clean with our limited facilities.' Occasionally, indeed, the environment here proves to be literally intolerable.

'Such conditions can scarcely lay claim to the term civilized. What must be the impressions of our prospective citizens toward the Government that meets them with this welcome to the promised land? The Government can hardly excuse itself on the plea that the immigrants come of their own volition and not at the Government's invitation. The aliens come in good faith with the knowledge that they must pass the governmental inspection. It is through no choice of their own that they become our involuntary guests. The primary dictates of humanity point the need of radical reform in existing conditions and standards. There is no sufficient reason why Congress should not be willing to expend for the proper enforcement of the immigration laws at least the amount collected from head tax on immigrants. As a matter of fact less than half that amount is ordinarily consumed.

'The erection of a modern immigration station at the port of Boston was authorized by an act of Congress approved Feb. 23, 1909. The sum of \$100,000 was appropriated, a part of which was spent for a site in East Boston. By reason of a proposed change in the harbor line the original site was exchanged for another, which involved an additional payment. In succeeding years the sum of \$275,000 was added to the original appropriation, making a total of \$375,000. Plans were eventually prepared. In June, 1914, somewhat over five years from the date of the authorizing act, the Government is advertising for proposals to erect the station.

'The weakness of the present medical inspection at Boston, is due to the lack of adequate provisions for making what may be called the secondary examination in the case of those individuals, who, at the primary examination, are recognized and detained as abnormal. The lack is general in its nature. There is in the first place an insufficiency of medical inspectors. Finally there are no hospital accommodations at the immigration station. It thus becomes necessary to transfer a large proportion of those cases requiring extended examination, physical or mental, to various local hospitals and to depend upon the staffs of those institutions for the actual examinations. And in spite of the various makeshifts to overcome existing handicaps, tardiness in completing the medical examination of arriv-

ing immigrants has been a subject of frequent and justifiable complaint.'

MEMORIAL RESOLUTIONS.

RESOLUTIONS OF THE STAFF OF THE CARNEY HOSPITAL ON THE DEATH OF DR. HASKET DERBY.

Resolved (1), That in the death of Dr. Hasket Derby, the Carney Hospital has lost one of the oldest members of its staff, and the founder of the eye department of the hospital, with which he was connected for 37 years;

(2) That the staff has lost a strong and loyal worker, and one who has been ever conscientious and just;

(3) That the profession has lost a distinguished and active member, a specialist from the beginning, whose good works and efforts in the cause of ophthalmology here and elsewhere have long been recognized;

(4) That Dr. Derby's many friends, while feeling keenly their loss, will recall with the deepest pleasure a pleasant companion, a man of polished manners, genial conversation and high ideals; and

(5) That these resolutions be spread upon the records and that copies of them be forwarded to Dr. Derby's family, and to the BOSTON MEDICAL AND SURGICAL JOURNAL for publication.

(Signed)

FREDERICK W. JOHNSON,
DANIEL F. MAHONEY,

Committee.

RESOLUTIONS OF THE STAFF OF THE CARNEY HOSPITAL ON THE DEATH OF DR. JAMES G. MUMFORD.

ALTHOUGH his later work called him elsewhere, Dr. James G. Mumford was in his early professional life connected with the surgical staff of the Carney Hospital. It is fitting, therefore, that some expression of our regret be put on record. Hence, be it

Resolved (1), That in the death of Dr. James G. Mumford there passed a man whose life splendidly exemplified a spirit of rugged honesty, patient heroism and sincere devotion to his profession that has seldom been equalled and that is in every way worthy of emulation;

(2) That to us who are still in the ranks of the workers, the memory of his life should be a forceful aid in holding fast to the ideals of our profession and in enduring with courage and equanimity the burdens that life may put upon us; and

(3) That an expression of our sympathy be forwarded to Mrs. Mumford, and that these resolutions be spread on our official records and that a copy be sent to the BOSTON MEDICAL AND SURGICAL JOURNAL.

(Signed)

JOHN T. BOTTOMLEY,

Committee.

Correspondence.

THE TREATMENT OF DRUNKARDS WHO BECOME PUBLIC CHARGES.

Boston, February 26, 1915.

Mr. Editor: Over 100,000 arrests for drunkenness are made in this state every year. The expense thereof to the Commonwealth must approach, if it does not exceed, a million dollars annually. For more than a century these people have been treated as criminals by arrests, fines and imprisonment. What has been the result? Aside from the temporary relief to the community, practically nothing has been gained by this mode of procedure. Few, if any, have been reformed. On the contrary character has been smirched, self respect has been destroyed, many have become social outcasts and not a few have become criminals, and the evil is steadily increasing.

In view of past experience the policy of treating inebriates as criminals has been anything but satisfactory in a sociological sense. While some of these unfortunates are mentally defective, yet all are lacking in sufficient will power, or in a disposition to resist the desire for alcohol. In other words, by the abuse of liquor, they are rendered unfit to care for themselves or their families. Somebody must do it for them. The problem is, what shall be done with drunkards who become public charges.

The most sensible scheme that has hitherto been suggested lies along the following lines. Instead of sending intoxicated persons to station houses, or jails, let them be taken to detention hospitals, which shall be a clearing house for the reception and disposal of these cases. Simple drunks may be cared for there until they are sober, when their ultimate disposal will depend upon conditions. Delirium tremens, feeble minded and insane cases are to be sent to appropriate places for treatment and control. Inebriates should remain in custody, until in the opinion of the proper authorities, they are sufficiently recovered to be entrusted in the community. On leaving an institution they should remain under supervision of the officers of the out-patient department of the reception hospital so long as may be necessary. These unfortunate victims of the drink habit should be encouraged and guided, and made to feel that there is a place for them to fill decently and well in the community, that they are neither criminals nor hopeless defectives. Through various means, not a few inebriates have been made useful citizens.

Massachusetts has wisely adopted this policy and it only remains to carry it to its full development. It has established the Norfolk State Hospital for male drunkards and drug victims. The farm consists of 1,000 acres of land beautifully located about 20 miles from Boston. Buildings for accommodation of two hundred inmates have been erected and are in use. The hospital is over-crowded and should be enlarged so as to at least double the present capacity as soon as may be. The work now being done by Dr. Neff and his assistants justifies a liberal expenditure for the further development of the institution. More than one-third of those who have passed through this hospital have been distinctly benefited, a result that has never been obtained in this Commonwealth under any other plan.

Instead of spending their time in loafing, smoking, playing cards, billiards, etc., as was formerly the custom in retreats for inebriates, these patients are required to work at appropriate occupations under careful supervision, thereby compensating the state very so much for the expense incurred in their behalf. To complete the scheme a certain portion of their earnings should be devoted to the support of their families, or dependents.

The chief object of this note, Mr. Editor, is to call the attention of the medical profession to this admirable work and to urge its members to favor its

prosecution to its fullest possible extent. No more important sociological problem faces the community today. None realize the havoc produced by the abuse of alcohol more keenly than the physician. (A medical friend once told the writer that prohibition in his town was worth a thousand dollars a year to him!) To say nothing of the economic waste, the misery and suffering, both mental and physical, of the unwise use of liquor are well known to everybody. While complete reform of the evil is not to be expected, yet much can be accomplished by well-directed efforts along rational lines. The Norfolk State Hospital offers the best opportunity for this work known to this generation. The members of the legislature should be seen personally by the physicians of the state and urged to grant the appropriations asked for by the trustees of the hospital to extend its facilities for the important work in hand. The medical profession is not backward in doing its duty by the public. Here is another opportunity to help a most worthy project.

GEORGE W. GAY, M.D.

A MISAPPREHENSION CORRECTED.

Boston, February 23, 1915.

Mr. Editor: Although it is very repugnant to my feelings to call any public attention to troubles of my own, I feel compelled to ask your assistance in contradicting a statement which has recently been brought to my attention from several sources among the profession and the laity, viz.: that I have retired from practice and am giving up my cases to others. I feel impelled for more reasons than one, therefore, to make a somewhat public statement that there is not the slightest truth in any such report. It is neither my intention nor my wish to retire from the practice of my chosen specialty, to which I have devoted many years, while my health remains as excellent as at present, and so long as my colleagues in the profession, or patients, are kind enough to seek my counsel.

With my apologies for what seems to me a necessary encroachment on my part upon the time and the patience of yourself and your readers, I am

Very truly yours,

VINCENT Y. BOWDITCH, M.D.

APPOINTMENTS.

Dr. A. Bethe has been appointed professor of physiology at the new German University of Frankfurt and *Dr. Rudolph Höber* has been appointed professor of physiology at the University of Kiel.

The following veterinarians have been appointed to constitute the staff of the New Angell Memorial Hospital for Animals: *Dr. F. J. Flanagan* of Toronto, Chicago and Philadelphia; *Dr. H. F. Dailey* of Philadelphia; and *Dr. D. L. Boulger*, *C. A. Boutelle* and *J. B. McDonald* of Boston.

RECENT DEATHS.

DR. FRANK FULLER, who died on February 19 in New York City, was born in Boston in 1827. He early began the study of medicine as an apprentice to *Dr. Benjamin Hubbard* of Plymouth, Mass., and later studied dentistry under *Dr. John Gunn*. He began the practise of his profession as a physician and dentist at Portsmouth, N. H., in 1860, but at the outbreak of the Civil War entered the Second New Hampshire regiment with which he went to Washington. He was soon appointed secretary and later governor of the Territory of Utah and administered its affairs throughout the war and for some time thereafter. In 1874 *Dr. Fuller* returned to New York where he continued to reside until his death.

DR. HENRY L. NICHOLS, who died recently at Sacramento, Cal., was born at Augusta, Me., in 1823. He began the practise of his profession in Augusta but removed in 1865 to Sacramento, where he served for many years as city physician. He is survived by one sister.

DR. CHESTER MONROE BAKER, a graduate of the Long Island College Hospital in 1896, died at his home in Hyannis, Mass., Dec. 12, 1914, aged 39 years. He was a Fellow of the Massachusetts Medical Society.

DR. JAMES JOSEPH SCANNELL of Brighton died at the Carney Hospital, South Boston, Mass., February 19, of pneumonia, following an operation for ulcer of the stomach. *Dr. Scannell* was born in Boston Sept. 28, 1875, and was a graduate of the Tufts College Medical School in 1905. He was made assistant director of the bacteriological laboratory of the City of Boston in 1910, succeeding *Dr. B. L. Arms*, and later became director, a position he filled at the time of his death. He was a Fellow of The Massachusetts Medical Society and of the American Medical Association. He is survived by his widow, three daughters and two sons.

DR. HENRY CECIL HAVEN died of heart disease at his home "Glenburnie" at Stockbridge, Mass., February 19, aged 62 years. He was born in New London, Conn., Sept. 15, 1852. He was graduated from Amherst College in 1873, and from the Harvard Medical School in 1879. He practised in Boston from 1879 to 1899, being physician to the West End Nursery and Infants' Hospital, and physician to the Children's Hospital for a part of this time. Then he removed to Stockbridge, where he has since resided. He had been

a Fellow of The Massachusetts Medical Society since 1878. He married Mrs. Isabel Winthrop in 1899. She died in 1905.

DR. DAVID HYSLOP HAYDEN, a Fellow of The Massachusetts Medical Society since 1869, and its librarian from 1872 to 1884, died at his home in Lynn, on February 21, aged 75 years. He graduated A.B. at Harvard in 1859 and M.D. at the same university in 1863; was assistant surgeon in the navy during the Civil War, and afterwards studied in Paris and Vienna, and then settled in practise in Boston but was obliged to retire on account of ill-health; since which time he had resided in Newport and later in Lynn. He is survived by one daughter.

DR. JOSEPH PALMER WATTS, a Fellow of The Massachusetts Medical Society, died at his home in Wakefield, Mass., February 18, aged 32 years. He was a graduate of the Harvard Medical School in the class of 1905.

DR. HENRY CUTLER BALDWIN, of Boston, died of uremia at the Massachusetts General Hospital, February 25, aged 55 years. *Dr. Baldwin* was born in Roxbury October 27, 1859, and was a graduate of Harvard College in the class of 1880 and of the Harvard Medical School in 1884. He was for many years physician to out-patients at the Free Hospital for Women, and later, and up to the time of his death, physician for diseases of the nervous system at the Massachusetts General Hospital. He was a member of the American Medical Association, a Fellow of The Massachusetts Medical Society, a member of the American Neurological Society, the Boston Society of Psychiatry and Neurology, The American Medical and Psychological Association, the Boston Medical Library and the Boston Society for Medical Improvement. He is survived by his widow.

DR. CHARLES OSBORN TUPPER, who died of influenza recently at Brooklyn, N. Y., was born at Amherst, Nova Scotia, in 1862, a son of a physician. He received his medical education at the Medical College of Arcadia, Canada, and at the Jefferson Medical College, Philadelphia. He had practised his profession in New York since 1888. He is survived by his widow.

SOCIETY NOTICES.

MASSACHUSETTS SOCIETY OF EXAMINING PHYSICIANS.—A meeting will be held March 10, at Hotel Lenox. Dinner at 6.30 P.M.

Papers will be read by:

1. *Dr. Rosalie S. Morton*, Hon. Chairman of the Public Health Education Committee of the A. M. A. "The Effect of Industrial Strain on Working Women."
2. *Dr. Richard C. Cabot*. "Social Service as an Aid to the Physician."
3. *Dr. J. W. Sever*. "Massage and Manual Manipulation in After-Treatment of Fractures and Allied Conditions."

All members of the profession interested are invited.

J. H. STEVENS, M.D., *Secretary.*

NORFOLK SOUTH DISTRICT MEDICAL SOCIETY.—Meeting for Medical Improvement at United States Hotel, Boston, Thursday, March 4, 1915, at 11.30 A.M.

Reader: *Dr. Oliver G. Tinkham*, of Boston, Mass., for *Dr. C. A. Sullivan*, of South Braintree, Mass. Subject: "Vein Infection."

F. H. MERRIAM, M.D., *Secretary,*
South Braintree, Mass.

Address

SUPERSTITION AND THE DOCTOR.*

By OWEN WISTER, PHILADELPHIA.

DEEP down at the feet of the sky-scrappers in our cities, hordes of men crowd and pass incessantly. The intersecting streets cut slits between tall, sheer blocks of commerce, and all day long through these the traffic pours. From a top story you can watch the human specks below. Some of them hurry, some loiter, meeting and parting. They are in vehicles or afoot, they forge ahead, fall behind, keep abreast—but whatever they do, without end do they move and mingle and pass. Yet their sum is stationary, the concourse is always there. Specks join this mass and leave it on their particular orbits, but itself is a constant spectacle, down on the floor of the great stone valley between the sky-scrappers.

Constant through each year this spectacle has been constant through all the years since cities have stood upon the earth; the changing specks, the unvarying throng, the presiding walls of commerce, justice, religion. Look back across the stretching ages to the earliest day we know; two-wheeled chariots, kings, prophets, conquerors, slaves, naked athletes and painted idols—these gleam against that distant dawn, and from these the throng unbroken comes down between Grecian pillars, and Roman walls, and Gothic arches to us and our automobiles. A vast and

motley panorama of change—but how deep does the change go? What things happen in our throng, unknown to London when Chaucer was there, unknown to the Rome of Caesar, or unknown six thousand years ago where Babylon's temples rose above the specks that peopled its two hundred square miles of area? Babylon's patron god was Marduk—but what new gods can change the eternal identity of the crowd, and what new variety of man has been discovered since Sargon of Akkad built sanctuaries by the river?

Ourselves—for this is exactly what we shall here attempt to consider in a certain particular light—ourselves today, together with ourselves while we were building the pyramids, and all the peoples between that time and the present—we, the human race, have not had time to change much. If this earth, our planet, has a point of view, we have been here only a day or so in her count of time. Our own records don't go back ten thousand years; to her we are newcomers; she waits to know us better before according us her intimacy. On the other hand, we regard an acquaintance who has reached the age of eighty as being very old—and in this we are perfectly right. A thousand miles is a long walk, but no distance to telegraph. And, as we can easily think of a thousand miles in these two ways at once, so for our present purpose must we think of ourselves in two ways at once—as having existed on the planet both a long while and a short while; that is our double relation to Time.

As the features and anatomy of men persist, so do the component parts of the crowd. Dissect it, take its various specks and classify them,

* An essay read April 29, 1912, before the College of Physicians, Philadelphia; and Dec. 14, 1914, before the Johns Hopkins Historical Society, Baltimore.

some will be rare, some numerous, but all will be repetitions. We worship, we speak, we dress, on and on through the ages, and through the ages we govern, trade, fight, carve, build; the professions are perpetual, and since the beginning, man has but iterated and reiterated himself—only ever more and more articulately.

Rain, rain, go away,
Come again another day.

Have you heard something like this before? The children of England have been repeating it for no one knows how many generations. The children of Athens had their version of it before Sophocles danced at the theatre; their chant ran:—

ἔξῃχ' ὦ φῶς ἦλαε
Shine forth, sweet sun!

What chronicle, no matter how archaic, that does not include the priest, the soldier, the statesman, the lawyer, the doctor, the money changer, the merchant, the man of science, the scholar, the artist, the writer, the man of idleness, the man of crime? We might perchance add to these a certain eternal couple, the charlatan and the genius—the man of shams and the man of dreams—they are the chief characters in the drama of mankind, and we shall come upon them continually in this discourse; but they generally appear wearing the aspect of one of the others, and so fall not quite accurately into classification with the rest.

To see ourselves as classified dots in a procession six thousand years long is to see that our similarities to the ancients are really greater than our differences from them; and it seems that we are all about as wise and about as imbecile as we were in the days of Sargon of Akkad, and ten fools in Babylon could match any ten in America. Time has neither killed nor created anything in us. Our mental costume changes, not our mind. Behind a long series of masks, Credulity's face is identical, and we can be divided into those who believe that twice two makes four and those who believe it can make five if you find the secret. Or take the Philosopher's Stone. We smile at the fond alchemists, but in the year 1911 in these United States \$77,000,000 were paid to get-rich-quick fakirs, now convicted of fraudulent use of the mails. Seventy-seven millions to fakirs who have been caught—how many millions more to those uncaught? Their schemes were far more transparent to common sense than ever Alchemy was to the mediæval mind. But it is not alone in our crass foibles that we repeat the ancients; we are also like them in more flattering ways, and here is a subtle example. In our medical writings, delicacy leads us to avoid certain Saxon terms, and employ Latin in their stead. As we use Latin, the Latins used Greek. It is from a Roman medical treatise I take the following sentences:—

"The terms . . . are among the Greeks tolerable enough, and now in general use; for they are met with in almost all medical works and

treatises; our vernacular terms are coarse, and not . . . in use among those who had a due regard to modesty in their discourse."

This was written 2000 years ago. And since I am quoting Celsus to show the ancients and ourselves identical, let me quote him again:—

"It is of importance to know whether fatigue has brought on a complaint, or thirst; whether it has been occasioned by cold, heat, or watchfulness, or by hunger. . . That which singly has not the power of exciting disturbance may, conjointly with other causes, do so in the highest degree. The man who is free from disease and vigorous. . . ought not. . . to require. . . the physician. . . He ought to vary his mode of living; sometimes to pass his time in the country, sometimes in town, but more frequently in the open fields. . . But although exercise and food be necessary, the training adopted by wrestlers is superfluous. . . because when the training is interrupted by urgent business, the system becomes depressed, and bodies brought in this way to a high condition very soon age and fall into a state of disease. (You see Celsus knew this before the careers of some of our graduate athletes led us to discover it in the last twenty years.) "But for the delicate" (continues Celsus), "in which class may be enumerated the majority of persons living in large towns, and almost all literary characters, stricter precaution is necessary, in order that they may regain by vigilance what they lose from the very nature of their constitutions, places of abode, and occupation. . . Now the chief means. . . is exercise. . . more severe with him who has been studying less hard . . . and gentle with him who is exhausted."

I suppose that many a good lesson has been learned and forgotten several times in the course of history, and that at each re-discovery our complacency has called it "modern."

This Aulus Cornelius Celsus was a blend of various capacities; he wrote, beside his medical treatise, three others, upon the military art, upon rhetoric and upon agriculture. He serves to warn us—if warning be necessary—that in dealing with the changing specks and the unchanging professions we must not be too clear-cut or too dogmatic in our classification. Michael Angelo was another blend of several capacities; it were easy to name many more. Does not every man contain all his ancestors? Most of these are silent in him. They will take their turn at speaking aloud again in the generations that spring from him. Yet here and there in our own acquaintance do we come upon these blends of capacities, these individuals in whom more than one ancestor is articulate. We know great doctors who have written famous novels; great lawyers whose dearest taste is exquisite pictures; in Boston we all know of a banker whose desire was to have been a musician, and who has consoled himself by giving a great orchestra to his city. Therefore let us emphatically recognize that many a man could have specialized va-

riously; could have walked with credit along two or three paths, and in our sketch of the evolution of the doctor, and of the fragments into which the original prehistoric healer has been gradually split, our stress is to be laid exactly upon the multiplicity of the ego, upon the Chinese nest of characters that any one of us may well be.

We human beings remain so strange, so elusive, so inveterately beyond all logic, that self-contradiction is part of our very harmony. What do we see at the beginning of every doctor's prescription? A sort of thing that looks like an R, but this is the crumbled remnant of the symbol of Jupiter. Astrology still keeps the tip of her finger in the pie. Whatever be our gods, is there one among us who does not foster a pet private superstition tucked away in some crevice of his reason? Dinners of thirteen are seldom eaten at ease. In Baltimore two lives were lost by fire in a house whereof the street number was thirteen. Thereafter nobody would rent it until its number was changed to eleven-and-a-half. Friday is not a favorite day for starting upon a voyage, even with some landmen. Thus, from the Crucifixion and the Last Supper do we derive not only our salvation and sacrament, but also the two curses which hover over Friday and thirteen. Scarce a week goes by but we see an acquaintance "touch wood" by way of propitiation to the unseen powers; nor is it altogether in jest that he does so; it is the ancestral impulse of magic surviving in him, although he seldom knows it is the virtue of the true cross he thus invokes. Undying is our animism, our pantheism, our "vecchia religione"; science has not killed our intuitive affinity for signs, charms, amulets and methods occult; fragments of the most ancient divination survive with rites and observances gathered from each succeeding epoch. A sick Australian native is still connected by a thread with the magician, and thus cured. "Absent treatment" is our American wireless form of this. The Italian in our slums still takes home the doctor's prescription, and, holding it, watches oil dropped in a bowl of water. As the drops float left or right, the omen declares for or against the prescription. To be sure, says some one, such puerilities are to be expected in Australia and in slums, but hardly among those who dress for dinner and have a box at the opera. Yet I know a doctor whose patient wrote to him from Bar Harbor that her pet dog had bitten her. The dog was quite well, but had it not best be killed, lest it subsequently go mad and the bite prove dangerous? The hostess we dine with may not carry a rabbit's foot, but she may likely enough gaze in a crystal ball, or possess and credit a horoscope. It is not many years since *Planchette* frightened fashionable society most agreeably, and the future is still read in the palms of many hands.

The late head of the British Museum was an ardent believer in astrology. Puerilities we may

call these things, *Planchette*, the drops of oil, the crystal ball—puerile we may consider the eminent scholar in the British Museum, as well as the following extract from an important newspaper:—

"DAILY HOROSCOPE.

"The Stars Incline, But Do Not Compel."

"Wednesday, April 17, 1912.

"Mercury doth teach

"Subtle wit and speech.

"Under this rule astrology warns people to beware against those who use subtle arguments, hair-splitting speech and logic and specious, witty wheedling words and actions.

"It is declared also to be a day when it is well to be extremely cautious in dealing with fickle and whimsical persons and with those who change and vary in their opinions and desires.

"It is held to be an unfortunate day for indulging in caprices, moods and passions.

"Mercury in beneficent rule is said to grant keenness of perception and intuition this day, and also to enhance the originality and resourcefulness.

"Invention, science, mechanical skill, artistic crafts and processes that require deftness are said to be ruled with extraordinary power for luck this day.

"Saturn, rising over the United States at this period of new moon, does not make a fortunate aspect and afflicts particularly the east. Uranus, on the upper meridian, is held to make an influence for strange attitudes on the part of large and powerful classes, leading them into erroneous channels. It is predicted that there will be an unusual amount of political excitement and much discord among the various governing bodies.

"New York, it is stated by English astrologers, is under a rule foreboding great afflictions, depression and discord.

"There also is a sign governing the world in general, foremening disasters at sea."

"It is an evil lunation for rulers.

"Herbal astrology selects today as good for parsnip, dill, carraway, carrot, endive, fern, lavender, licorice, lily of the valley, hazel nut, marjoram, olive, mulberry, oats, myrtle, parsley, valerian, savory and calamint under Mercury

"It is also said that household signs are excellent for baking.

"Persons with this birth-date are ruled for success and achievement during the twelvemonth, but should beware against temptation to deceive a friend.

"Children born today are ruled under signs that are read as powerful for constructive energy and foresight in planning."

Well, what is the significance of this? The significance of such paragraphs being printed in the midst of news about Wall Street, the Republican party, and April changes in railroad timetables? One thing it points to, that the human race clings inveterately to its childhood; that Horace may be skeptical about the "Babylonian numbers," that Savonarola may condemn astrology—yet that Kepler, in spite of his great scientific genius, will, nevertheless, cast a horoscope for Wallenstein; that Harvey and Descartes may overthrow the mystic "spiritus animales," only for Animism and Vitalism to arise equally mystical, in their turn to be dispelled by modern chemistry, by Darwin, Helmholtz and Haeckel; that Swift in the eighteenth century may kill

* This prediction followed the Titanic disaster very promptly.

star-gazing, only for it to revive vigorously in our morning newspapers. To our childhood do we cling, indeed—but for the true moral we shall not be ready until we have done some further traveling up and down the centuries. That palmistry (to cite another instance) was known in China 3000 years before Christ, and has survived several religions and several civilizations, and still goes marching along unchanged, while Edison and Marconi and Curie flash upon us their miraculous discoveries—this is something to be taken into our intellectual account.

Our shudderings and our mutterings are long-descended, and the quacks are almost the oldest family in the world. What the first incantation was we are not likely ever to know, but most of us are familiar with that one which is probably the latest: "There is no sin, sickness or death." Many patients have been bidden to repeat this over and over as part of the ritual of their treatment. It seems quite as sensible as a rune I used to chant once:—

Eeny, meeny, moaney, my,
Butter, leather, boaney, stry, etc.

In syllables almost identical the Celts once counted their sheep. The triangular word *Abacadabra* (which in Hebrew means "I bless the deed") was a respectable and established remedy for fever and ague, A.D. 212; but jargon was chattered over our ailments earlier than this. Cato the elder, that preëminent curmudgeon, who properly hated the Greeks for teaching soft vices to the Romans, and improperly hated doctors because they then all came from Greece—Cato used to practice a little surgery on his farm, about 200 B. C. When his laborers brought him their swollen joints, he would say, not

Double, double,
Toil and trouble,

but

Huat hanat
ista pista sista
damiato
damnaustra.

Whence did he derive this? Was it a little thing of his own? We must pause at this Cato for one moment; he is so like ourselves. He was a shrewd, hard-headed business man of Rome, who saw clearly that Carthage's looming commercial competition must be headed off by the destruction of that city itself; yet Cato quacked over swollen joints. I suspect he did not invent those syllables, but borrowed (or varied) something older, just as different children have different versions of Eeny, meeny, moaney, my. Listen to this:—

Shabrirli
beriri
riri
ri.

That is an ancient Hebrew incantation, and here is part of one from Babylon:—

Ki
risch-ti li-bi-ki
risch-ta la li-bi-ki
la li-bi
pisch.

Thus does the incantation, jargon, quackery come trickling down the ages to us: Risch-ti la li-bi-ki, Shabiri beriri, Huat Hanat, Abracadabra eeny, meeny, there is no sin, sickness or death, do we not detect family resemblances throughout? There's rhythm, alliteration and nonsense, the very things that sensuously impress credulity. When Cato quacked over his plowboy, the plowboy felt that something potent and above his comprehension was being set in motion for him, and his sore joint, if the swelling wasn't very serious, was doubtless helped by his state of mind. We have good ground to believe that the old word quack-salver (whereof the resemblance to quicksilver is purely accidental) means him who salves, who saves, who heals by jargon, by quackery. Without scientific confirmation, I can merely venture to hazard a guess that in all these incantations a primitive germ of "suggestion" is to be found. And when the doctor writes his prescription at our bedside, don't some of us suspect a special virtue in his hieroglyphs? And don't we half nebulously imagine that if he would bestir himself and employ *all* the knowledge which hides behind his impenetrable eye, he could work real special miracles in our behalf? The power to imbue us with this mystic confidence is what we term today a good bedside manner; it is a survival of white magic, and is essential to our welfare; he whose faith in doctors is decayed is ripe prey for charlatans.

It is tempting to run riot among the strange examples of this ingrained ancestral credulity which lies in us so deep, and crops out in such protean aspect, but I will tax your patience with only two cases more, and these from personal experience. In a New England State, since Colonial times, has lived a family of natural-born bonesetters. One of these unlicensed hereditary practitioners unquestionably cured Theodosia Burr of hip trouble when the surgeons of New York had failed. Today any jury of that State will take the word of an unlicensed bonesetter against the sworn testimony of an educated, licensed physician. (There is in this a seamy side of American democracy, but I will not open that door. The bone-setting hereditary gift is a fact just as authentic as is the "jumping Frenchman" of Canada.)

In the same State, and within the sound of the whistle of the express trains between New York and Boston, a family who were suffering from anemia dug up their recently buried sister and roasted her liver to stop her from "vampirism" them. Now, at the end of the nineteenth century, for that is when my anecdote occurred, the liver of the New England Yankee woman

was roasted because six or seven thousand years ago people believed that the liver was the seat of the soul. Only thus could the vampire be killed. On this liver we fly straight back from New England, through Britain, the Middle Ages, Rome, Greece, Egypt to Babylon, where we have to stop for lack of earlier records. In spite of the telephone, we resemble the mummies—the set fractures of whose bones, by the way, give proof of a clearly developed knowledge of surgery.

In the Yankee vampire, Solomon, visiting New England, would have recognized at once an old acquaintance—Lilith—although he might have to visit Borneo or Burma or Uganda, to see divination by the liver in actual practice. In our down-town streets he would very naturally mistake our banks and stock-exchanges for temples of the gods; but wherever he went, he would hum his old maxim, that there was nothing new under the sun. Much that is done by the Hudson and Mississippi they did by Tigris and Euphrates.

In attempting to discern the silhouette of the doctor against the various receding backgrounds of history until all outlines are merged in the mist of the primeval ages, two wholly contradictory thoughts arise; one wonders how the doctor, when once he had emerged as distinctly as he did in the person of Hippocrates, should not have gone on growing ever clearer and clearer, like a photograph developing on a plate, instead of presently becoming dimmer and more dim, until he grew virtually invisible for centuries. And on the other hand, one equally wonders how the doctor ever emerged at all. He was no money changer or lawyer or merchant. He was far different; he was merged with the multitudinous and ubiquitous quack—the quack self-deceived and the quack self-confessed; he was stirred into the same cup with priests, astrologers, patron divinities, magicians, witches, prophets. Superstition held him in her hand, and closed her hand over him. Let us greatly foreshorten as we review his evolution, and from it distil morals useful for ourselves and our children.

Of course we don't know when he began. Scholars don't know, but we may all boldly guess that he began pretty soon. Somebody must have been hurt in battle or in hunting, and discovered some neighbor particularly successful in giving him relief. This must have constantly happened ages before Ea, god of light and beneficence, healed the sick and raised the dead. There would the doctor have been, already quite emerged, quite on his own feet. But the sun, rain, lightning, thunder were too much for man's imagination. Many gods, good and bad, evidently encompassed man. Religion, therefore, controlled every least act of his life, and thus we find the priest at the root of every doctor's family tree. He was at the root of many other professions besides religion and medicine; he declared the law, regulated education; he swayed armies; he ruled trade and domestic life and ag-

riculture and migration; he was the first statesman, and his doctoring was as public an office as any of his other offices. With a proportion of truth much greater than when uttered by Louis the Fourteenth, the priest of archaic ages could have said, "L'état c'est moi." And by the time intellectual evolution had reached the stage of revealed religion, literature had appeared, and of this also the priest took control, and by this means, by the means of sacred writings, he ordered and presided over the community and became the central power of the state. The Pentateuch contains what is to us the most familiar example of these various revealed religions, and the thirteenth and fourteenth chapters of Leviticus give an admirable instance of the priest in medicine. They are a mixture of close, accurate observation on the one hand, and of incomprehensible rites on the other. "If the plague of leprosy be healed in the leper, then shall the priest command to take for him that is to be cleansed two birds alive and clean, and cedar wood, and scarlet and hyssop. And the priest shall command that one of the birds be killed in an earthen vessel over running water. And for the living bird, he shall take it, and the cedarwood and the scarlet and the hyssop, and shall dip them and the living bird in the blood of the bird that was killed over the running water. And he shall sprinkle upon him that is to be cleansed of the leprosy seven times, and shall pronounce him clean, and shall let the living bird loose into the open field." These symbolic and magical prescriptions follow upon an account of leprosy itself, containing directions about isolation and burning the patient's clothes, which are as rational today as when they were written. But from this we distil our first moral: In those ancient days the State, through the priest, regulated the practice of the healing art. The doctor's duty to the community came before his duty to the individual. That ancient relation between doctor and State will revive; is reviving.

It is from such therapeutics as Leviticus discloses (and innumerable parallels are to be found in other ancient literature, in the Vedic lore, in the Hermetic books) that we see physiology suffering a set-back—almost a strangulation—in its very cradle; a mystic, instead of a natural explanation of life gains headway; baneful, nay, frightful superstitions arise—such as a man's getting rid of his disease by transferring it to another. Naaman's leprosy clove to Gehazi by way of punishment; Death agreed to take the wife Alcestitis instead of the husband Admetos; the perpetuation of these fables can be seen almost daily in our criminal courts, for, though mysticism has at last let go of the doctor, it has not relaxed hold of the patient.

The significant, nay, the enormous fact for us to realize and remember is that charms, spells and rites in all these thousands of years have never advanced, never matured, while surgery and medicine, precisely in proportion as they

have shaken off the shackles of mysticism and dogma, have grown in their power to prevent and alleviate human suffering. Magic is stationary; magic hangs unchanged on a side offshoot of the great tree of evolution; it is science alone that we find in the main trunk of growth.

But, as I have said, the doctor's outline was very dim, long before and long after the date of Leviticus. He was encased in the priest, looked with the priest's eye, spoke with the priest's voice and continued to live in the nebulous clot of the supernatural that had been his birthplace. By the time we see him distinctly extricated from this, the nebulous clot has already been the parent of all varieties of "irregular" practitioners. Evidently these ancestral quacks, sorcerers, magicians, and so forth, were a class in ill repute, for we find very ancient laws forbidding people to have recourse to them. These laws were not at all based upon the idea of deception or sham, but on the belief that such people were in league with powers of evil instead of with the power of good which supported the priest or "regular" practitioner. It was a scandal to the pious when disease was for the first time roundly asserted to come not from the gods but from natural causes. The man who dared say such a thing was called an atheist; nor can we at this time quite realize the courage that such an assertion required. For during those early eras in India, or Assyria, or Egypt, or wherever, the gradual specialization of man had logically caused an equivalent specialization of gods, patron divinities multiplied, and I need only remind you that Thoth, Hermes, Apollo appear (with others) in connection with healing. But these greater personages were by no means all; the human body came to be parceled out among several dozen little gods, each with an exclusive territory, seldom bigger than the thumb joint. Whenever a man felt any pain, the divinity presiding over that particular spot was to be duly propitiated. From the cult of disease-making the belief naturally followed that illness was a devil inside the patient—and here we meet the origin of the nasty stuff our grandparents had to swallow in such quantities. In order to disgust and drive out the disease devil, large doses and monstrous compounds of dreadful taste were swallowed. We can note in this devil, too, the archaic symbol of the modern germ. Had we not been reminded by various illustrations that superstition is just as vigorous today as ever it was at any time, it would surprise us to find moving along abreast with the patron gods, a rational, concrete observation and practice. Although Tuesday and Wednesday, sacred to Mars and Mercury, were the prescribed days for blood letting, some elaborate and non-mystical surgery had come up among the Hindus, cupping was known, and, beside the setting of fractures, already mentioned, the Egyptians had specialized in ophthalmia. Nevertheless, Socrates said he owed a cock to Aesculapius; nevertheless, Aesculapius was

given a supernatural origin and education, and his temples were everywhere in the Grecian world, while Melampus began with the touching advantage of having two grateful serpents lick his ears. This taught him the language of birds and beasts.

Thus we get our impression of the early life of the Healing Art: a long, a very long infancy, a long, a very long childhood, full of fairy tales. It was thousands of years old when Babylon fell, yet it had not reached adolescence. In Homer, the doctor and the surgeon had become distinct, but rites and spells and sacrifices attended their ministrations. Nevertheless, the Trojan war (like many wars) caused an advance, both in practice and in observation, and so we reach a great milestone, 460 B.C.

Certain patches along the road of history blaze with light, while the stretches in between them look dull. One of these bright patches is a certain half-century in Greece, and the light from it to this day helps us to read many things. It would almost seem as if, flowing loosely and indefinitely about over our planet, were certain fertilizing forces of intellect, generally manifest in an average way, one century being usually as productive as another. But sometimes these forces seem to collect and glow as one for a while, emitting a lustrous and ineffable radiance. Thus, when the lamps of poetry, architecture, sculpture and philosophy were blazing in Greece as they have never simultaneously blazed since, it is natural that the lamp of medicine should also suddenly burn with a perfectly new light.

What makes Hippocrates illustrious along with his contemporaries Aeschylus and Plato and the rest, is not his intelligent molding into a system what the past—and especially the Pythagoreans—had indiscriminately handed to him—though this alone would have been a signal achievement. It took a fine mind to be the first to say:—

"Art is long, life is short, the occasion sudden. . . Experiment is indeterminate, generalization hazardous. . . Not only the doctor must do his part, but the patient as well, and the servants. . . For desperate cases desperate remedies. . . Whatever in connection with my professional practice. . . I see or hear. . . which ought not to be spoken of. . . I will not divulge." Thus speaks Hippocrates. It took a fine mind and a fine nature to utter such words. But it is not for this that Hippocrates is styled the father of medicine; it is because he dared to say that diseases came from natural causes, and not from the gods; Hippocrates walked out of the temple and sat down in his office. With that courageous act of deliberate self-conscious secularization the doctor's outline becomes at last distinct; he has emerged from Superstition and taken his place in Science.

Here is an epoch, indeed, in the psychic experience of mankind. It is as momentous as the discovery of Columbus, or the Reformation.

When Hippocrates dared to prove that epilepsy was not sent by the gods, the snapping of the bands of superstition made a sound that passed forward through ages, to be echoed back by Pasteur and Lister. Let it be repeated, we can hardly imagine the courage of such an act. Among the present company there may be those who, at one time or another, in upholding some principle, have run counter to the general convention of their friends, but theirs has been an adventure quite mild compared to that of Hippocrates. Is there a man here who has known what it is to stand alone and deny publicly by preaching and by practice some universally held political or religious belief? Attack the right of private property; many will be against you, but you will find fellow revolutionists. Declare that the story of the birth of Minerva is not a whit more mythological than what is asserted in the Nicene creed. . . you will shock some people, but by no means everybody. There is not in any American city at this moment one single social, political or religious belief that is shared and venerated by the community as a whole. Probably but once in the whole history of this country has a man known something similar to the experience of Hippocrates, and that was Garrison, when in 1830 he declared that slavery must be abolished. Yet even he was not as lonely as Hippocrates; for slavery had been already abolished in the rest of the civilized world, but all the world that Hippocrates knew believed that sickness was sent by the gods. Ah, to have uplifted your voice, and, amidst the general dissent, proclaimed a truth which goes on benefiting humanity 2400 years after you are dead—that is something to have done!

So this happened 2400 years ago. It opens the first chapter in the history of scientific medicine, and it brings our discussion again in sight of the sky-scraper. From the age of Pericles down along the centuries to ourselves, superstition and the doctor walk as separate beings, in spite of the long eclipse which overcast the mind of Europe. Before that huge and vast barbarian darkness set in, medicine and surgery were able to advance several steps, superstition, of course, keeping pace with them—even stimulated by competition with them. Moreover, Philosophy took Medicine by the hand and led her astray; Plato and Aristotle, by their theorizing, actually beclouded much of the good Hippocrates had done. Schools arose, and controversies about methods just as bitter as today, so that when Galen appeared about five centuries later he found medicine a house divided against itself, crumbling with all sorts of fancies and futilities, and it needed his great genius merely to rebuild, let alone to extend, the foundations. But Galen inherited what Hippocrates had never known, dissection. It is said by Celsus that the surgeons of Alexandria practised vivisection on condemned criminals, Alexandria arguing that a few malefactors could be thus utilized for the benefit of mankind at large. If this ever did

happen, humanity put a stop to it before long; and after humanity the church spoke, and not only vivisection but even dissection was for centuries forbidden or discredited.

Now while all this was going on in the rational department, the irrational was not idle. Amid the teeming harvest whereof Hippocrates was the earliest and splendid fruit, the ancient weeds took a new start. Astrology, which Greece transplanted from Babylon, where it flourished for public use, was by Greece converted to private use, and so passed on to Rome. Then, in transit anatomy became almost inextricably commingled with the planets, even at the very time when the human body was being rationally investigated at Alexandria 300 B. C. A custom of casting horoscopes, private and official, thence flourished uninterrupted for 1900 years, when (in the sixteenth century) astrology seriously affected trade. Furthermore, the temples of Aesculapius were not driven out of lucrative business because Hippocrates had renounced them and their works. We need only single out Alexander, the Paphlagonian. He conducted a particularly enterprising establishment, and during the plague, A.D. 166, his oracle issued a verse which was used as an amulet, and inscribed over doors. This Alexander bears a striking resemblance to some of our brothers who pass by the sky-scraper; he was a spiritual medium; he was a blackmailer, he and his will live and prosper as long as the human race continues upon this planet.

No wonder that such a man as Galen strove to lift medicine out of the stifling tangle he found it in; no wonder that Antoninus Pius passed laws regulating the practice of medicine. And here once again our moral recurs: Ancient medicine was controlled by the priest; with Antoninus the State lays its secular authority upon it, with ourselves, more and more, the State will take measures to supervise a class of men in whose hands lies the health of the community.

The vast European darkness fell upon the glory that was Greece, and the grandeur that was Rome. Through that long night the living spark of medicine did not quite expire. The Philosopher's Stone and the Grand Elixir kept it alive. In Italy, at Salerno, it glimmered quite steadily for centuries—until Napoleon. It wandered to Damascus and Bagdad; it inspired the Byzantine school. But mostly it smouldered beneath Sorecery, Palmistry, Monasticism—in sooth, beneath an asphyxiating mysticism; and beneath mysticism it was found in the seventeenth century, scarce brighter than Hippocrates and Galen had left it. One great, courageous man in the sixteenth century—Ambrose Paré—was not mystic, and braved the faculty, and was called a quack for bandaging amputated limbs instead of pouring boiling oil over them. We meet other great names—Paracelsus, for instance—but it was Wiseman and Harvey who really turned the spark to a flame. A spark it had been since 400 B. C., 2100 years; we know the flame it is become

in the last three centuries. We need not more than pronounce the names of Hunter, Jenner, Darwin, Lister, Pasteur; our story ends when medicine and surgery waked from their long sleep of superstition, and began again where Hippocrates and Galen had left off.

We have now taken a glance at the human family in a particular light, we have surveyed ourselves from sky-scraper to Babylon, that we might be reminded how little we have changed during our brief history. We have had to skip much; we have omitted the great renaissance of witchcraft following upon the Inquisition and the Scholiasts; we have described none of the outeries invariably raised against each important advance in Science—as against every other intelligent innovation. In one of our great cities, leading citizens bitterly opposed the introduction of illuminating gas for twenty years; in the same city, leading citizens undertook to prove theoretically that if anthracite coal were carried in a railroad car instead of in a canal boat, the coal would be reduced to dust by the vibration. The Governor of a great Southern State in recent years vetoed a bill providing for compulsory medical inspection of school children. May we not hope that the time is approaching when all schools and all colleges will be subject to such inspection, and people will speak of the former unenlightened prejudice against it, just as we speak of the prejudice against vaccination and chloroform? The Russians named the first child vaccinated among them Vaccinoff; a little girl, christened Anaesthesia, thus celebrated the fact that she was the first child born under the auspices of chloroform. Such events, great and little, and such instances, all through the length of history, we have perforce omitted—but had we been able to include them all, the whole testimony from the beginning until today would but show us what has been already shown—that superstition, credulity, prejudice, are indestructible. And how, indeed, can superstition ever disappear, while the universe remains a mystery? And when shall we understand the universe? Is there a person in this room, or in the world, who can explain why sugar tastes sweet and salt does not? Or how the perfume of the rose is wafted through the air? Some men can handle bees without being stung, and some can pick up scorpions and deadly snakes unscathed. It is not done by a trick; these are authentic facts, but even the men themselves do not know what personal quality it is that they use so strangely. We do not know why the grotto at Lourdes has undeniably been able to heal the wounds of certain patients deemed incurable by regular practitioners. What, then, is there that we wholly understand? Wherever and whenever we attempt to answer the questions Why? and How? we step off at once into the vast and featureless unknown. Therefore Superstition survives, no matter what Science may achieve; and we may call the Quack a constant by-product of that eternal surrounding mystery whence Science

from time to time draws a slender thread, a new clue, for the benefit of man.

What then, fellow patients, is the moral for us? Is not one moral, at any rate, that we should beware of our prejudices? Can we not imagine two Athenian ladies meeting on the day that Hippocrates made his great Declaration of Independence? Can we not fancy one lady walking up the fashionable street of Athens and meeting her friend in the fashionable Square of that classic town?

"Good afternoon, my dear friend! And who, O Penelope, is this profane upstart who would slander the immortal gods by declaring that they do not send us epilepsy?"

"I know not the fellow's name, O Parthenia! But surely he will be done to death for his great wickedness."

"Worse than wickedness, O Penelope! His shocking vulgarity."

And what, then, doctors, is the moral for you? Is it not, in one way, quite the same as it is for us—To live always with an open mind? No easy thing to do, by the way! The mystery of the hereditary natural bone-setter who was able to cure Theodosia Burr, the still greater mystery of the authentic cures at Lourdes—these and similar phenomena hold something that you may some day be able to formulate and control. During the sensation created in France by Mesmer, a committee of wise men was appointed to investigate and report upon the singular (though not wholly novel) pretensions which Mesmer had made. The wisest of them all, Benjamin Franklin, reported adversely as to the existence of the so-called mesmeric fluid, but he remained non-committal regarding the cures effected.

So much for an open mind—a passive duty. The doctor's active duty looms large. We have reminded ourselves that in the beginning of civilization he was combined in the same person with the statesman and the priest; we have seen him in the course of his evolution separate himself from the priest, and become secular. Then, in curious analogy to the archaic specialization of gods presiding over various portions of the human frame, the doctor in his turn has specialized, so that today we may say that he is divided into many fragments, one for the eyes, another for the ears and throat, and so on; yet, singularly enough, as our civilization grows increasingly complex, the doctor's path is leading him again towards a union or coöperation with the Church and the State. Once more, as of old, his duty to the community tends to come before his duty to the individual, because we are beginning to see the community's health as a unit.

Second, and only second, to a national ideal, is the nation's physical endurance and vitality and fertility. The strength of each generation's limbs, the cleanness of its blood, and the cleanness and soundness of those to whom it shall transmit life, this more and more must be the doctor's concern, must precede his consideration for the individual. We have learned to accept,

with diminishing protest, that yellow poster which marks our house when it harbors some dangerous communicable disease. To "free-born Americans" of fifty years ago, this would have been intolerable. But—man's inalienable right to life, liberty, and the pursuit of happiness, does not include the right to be infectious. We shall go further than the yellow poster. There are signs of it. Disease is not communicable only, it is also transmissible. In some parts of our country the law already prohibits certain classes of criminals from parenthood. But here we graze a thing called "eugenics." Now about eugenics there is at present a deal of overdone emotion and underdone reflection. Let us (if this is yet possible to the American people) restrain ourselves from dashing down foolish and hasty laws upon our Statute books. Such laws, when enforced, often work their precise reverse. If doctors and parents will drop the old-fashioned excess of reserve, and talk sense to boys and girls privately, public school-rooms need never be an arena for this delicate topic. Fewer asylums and hospitals, fewer untimely graves—this good end will not be best accomplished by bad means, by crude legislators and crass preachers. To denounce youth as vicious when youth has merely followed the impulse of adolescence, is futile, because youth will not believe this; other and juster reasons must be given, if youth is to listen and be controlled; and any young man, properly warned and properly informed, will not be merely willing but anxious to learn from his doctor before marriage if he is fit to be a husband and father.

From the shoulders of Hippocrates upon his descendants has fallen a mantle of great courage. Not the sailor, not the soldier, no man of any kind, has given his life so freely and with such serene gallantry as has the doctor. In his search to lessen human suffering he is dying daily, quietly, without sound of trumpets and drums. Inspired with physical and moral courage—not only to brave pestilence, but also, when need be, to face violent public opinion for the sake of a great cause, this is his hereditary duty, and his destiny, noble and exalted.

OBSERVATIONS UPON TEN CASES OF DIVERTICULUM OF THE BLADDER.*

BY HUGH CABOT, M.D., BOSTON.

IN 1912 I presented before this Association some observations¹ upon three cases of diverticulum of the bladder and I desire now to add to

* Read before the American Association of Genito-Urinary Surgeons at Stockbridge, Mass., in May, 1914.

¹ See JOURNAL, Vol. clxxii, p. 300.

the evidence at that time put forward. The two most interesting questions in connection with these pouches are: (1) Their origin, whether congenital or acquired; and (2) their management by operation.

CLINICAL EVIDENCE BEARING UPON THE ORIGIN OF DIVERTICULA.

In the discussion in 1912 I found myself at variance with the views expressed by Dr. Chute, to the effect that these conditions were acquired rather than of congenital origin. The acquired type must obviously be due to obstruction in the urinary tract at some point below the bladder, and it behooves the advocates of the theory that they are acquired to produce evidence of obstruction as it also behooves those who hold the view that they are congenital to show that these patients are not guilty of obstruction. Upon this question I have the following evidence to submit:—

CASE 1. J. H. G., 38 years. March, 1911. Symptoms began at age of 25. Autopsy showed bilateral diverticula with dilatation of both ureters, obstructive thinning of kidney tissue. Pylonephritis. There was no demonstrable obstruction in the urinary tract.

CASE 2. M. G., 30 years. May, 1912. Symptoms six months' duration. One diverticulum just above left ureteral orifice. Removed by operation. No urethral or prostatic obstruction. Operative recovery. Patient lost sight of.

CASE 3. L. L., 28 years. October, 1909. Known to have had cloudy urine without obvious cause for two years. One diverticulum just above right ureteral orifice. Removed by operation. No urethral or prostatic obstruction. Patient well. Clear urine 1913.

CASE 4. J. W., 29 years. June, 1913. Symptoms a year and a half. One diverticulum posterior wall of the bladder. Removed by operation. No urethral or prostatic obstruction. Good operative recovery. Patient lost sight of.

CASE 5. A. G., 59 years. August, 1913. Symptoms one year. Prostate moderately enlarged by adenomatous growth. One diverticulum just above orifice of right ureter. Operative removal of diverticulum and prostate. Slow but satisfactory convalescence. Urethral obstruction due to prostate.

CASE 6. W. R. B., 46 years. March, 1914. Cloudy urine of some years' duration. No other symptoms. Operative removal of left-sided diverticulum, into which the ureter opened. No urethral or prostatic obstruction. Patient still under observation.

CASE 7. G. B. C., 23 years. January, 1912. Symptoms two years' duration. Cystoscopy shows bilateral diverticula in neighborhood of ureteral orifices. Kidneys too far gone to permit operation. No urethral or prostatic obstruction.

CASE 8. C. E. K., 50 years. May, 1913. Symptoms eight years. Two diverticula on right side, one above, one below ureteral orifice. Operative removal. No urethral or prostatic obstruction. Operative recovery.

CASE 9. E. F. P., 50 years. March, 1914. Symptoms ten years. Seven years ago perineal prostatectomy. No relief of symptoms. Ten ounce residual continued. Two right-sided diverticula above ureteral orifice. Operative removal. Operative recovery. No urethral or prostatic obstruction. Empties bladder completely.

CASE 10. A. N. B., 72 years. July, 1913. Symptoms ten years. Prostate much enlarged. Right-sided diverticulum some distance above ureteral orifice. Operative removal of prostate and diverticulum. Now empties bladder completely. Urine clear. Urethral obstruction due to prostate.

Taking these ten cases together they show an average age for the onset of symptoms of 37 years, and though it is probably fair to assume that the condition must have existed for some time before the onset of symptoms, let us assume that it did not. Only two of them showed clinical evidence of obstruction, Cases 5 and 10. Moreover, obstructive lesions of the prostate are, to say the least, not common at the age of 37, and none of these patients had any demonstrable stricture of the urethra. For the other eight cases it seems to me logically to follow that the advocates of the theory of acquisition must assume that the cause lay in fetal life and has disappeared beyond the possibility of clinical demonstration. This is, I believe, the theory of Englisch. It must, however, be admitted that a condition giving rise to sufficient obstruction to force outward all the coats of the urinary bladder, and then disappear, leaving no trace behind it, belongs in the category of the miraculous. Upon the evidence submitted, and which I have been able to collect from other sources, it seems to me far more probable that these sacculations are of congenital origin, that they may, and do, exist for years without causing symptoms which, when they appear, depend upon the advent of infection. Entire quiescence must not, however, be taken to mean that these conditions are harmless since, as is well recognized, they occur most commonly in the neighborhood of the ureteral orifices. By their presence and by their extreme likelihood of producing pressure upon the ureter, they sooner or later produce ureteral dilatation, hydronephrosis and extensive destruction of the kidney. When thus situated they are therefore always a serious menace to renal integrity and not uncommonly destroy the patient. Those cases which have been discovered early and removed have been followed by complete cure.

Operative Management. It goes, I believe, without saying, that when a diverticulum of the bladder is discovered the indications for its operative removal are clear if the condition of the patient is such as to make recovery within the

bounds of probability. Two conditions in particular, apart from mere technical difficulties, will influence the result. First, the condition of the kidneys, and second, the amount of pericystitis and peri-diverticulitis, which result from long-standing infection. In Cases 1 and 7 the extent of the kidney damage was such as to constitute a positive contra-indication. Case 1 came to autopsy and Case 7 was clearly not likely to live long. A lesser degree of the same condition existed in all of the other cases except Case 3 and Case 10 and must therefore generally be reckoned with. The damage to the kidneys resulting from obstruction is not confined, in the case of unilateral diverticulum, to one side. With diverticulum there has in our cases been constantly observed very marked hypertrophy of the bladder wall, which is sufficient to increase the pressure around the ureteral orifice on the sound side and thereby increase the work and lead to dilatation of the ureter. This bilateral dilatation was demonstrated at operation in Cases 4 and 8, both of which were unilateral cases. Upon precisely what mechanism this hypertrophy depends is not to me clear, but its extensiveness I believe to be beyond question and its importance as a menace to the integrity of the kidney is certainly great. It therefore becomes extremely important to study the kidney function of these patients carefully before undertaking operation, though successful results may be obtained in patients with extremely low functions, as shown by Case 8, whose function was at no time above 10% by phthalein and whose average function was about 5%. Case 5 had a function of not over 15%, and Case 4, with a posterior wall diverticulum, a function of 25%.

Peri-Cystitis and Peri-Diverticulitis. The inflammatory reaction around these sacs is in some cases very great and has seemed to depend directly upon the duration and severity of the cystitis and diverticulitis. It not only greatly increases the difficulties of operative removal, which in all conscience are great enough in many cases, but when of severe grade and widespread, seriously compromises the future ability of the bladder to take up its function. This is aptly illustrated by Case 8, in whom the removal of the diverticula, which were extensive though unilateral, did not result in return of the contractility of the bladder. He has, during the year which has elapsed since operation, been free from his acute attacks of pyelonephritis, but his bladder still contains much residual and he is largely dependent upon a catheter. It therefore follows that the earlier these pouches are discovered and removed the greater the probability of a complete cure, such as resulted in Case 3.

Operative Technic. I believe it to be now fully demonstrated that no operation short of excision of the diverticulum can be expected to cure. Case 9 had his prostate removed years ago with great completeness but without benefit to his symptoms, as he continued to have a large

and increasing residual. Once these pouches have lost their contractility and given rise to residual urine, that contractility cannot be restored by removal of an obstruction, should such exist. The lesser operations of enlargement of the orifice of the diverticulum seem to me total failures. In one of our cases, Case 8, this was tried three years before my operation, without benefit and without even stopping the progress of the symptoms.

I shall, therefore, confine this discussion to the technic of excision of the diverticulum. In all cases, no matter where situated, the operation will be facilitated by the opening of the bladder, which not only enables the surgeon to identify accurately the position of the sacs but facilitates the dissection by what might be called the bimanual method, one finger in the bladder and the other hand upon the outside. From this point on, however, the operative attack should vary according to the position of the pouch.

1. *Diverticula on the Posterior or Lateral Wall, Not in Relation to the Ureteral Orifice.*

In these cases the position of the ureter and the consequent possibility of wounding it need not be considered, and the following technic has served us well: The bladder having been opened and the finger introduced into the pouch, the bladder wall is incised freely down to the neck of the pouch, which is then circumscribed, a clamp applied to the pouch and the rest of the dissection rapidly finished. The incision in the bladder wall, though long, has not seemed to me objectionable, and it greatly facilitates speed and avoids unnecessary trauma to the surrounding tissues.

2. *Diverticula Situated in the Neighborhood of the Ureteral Orifices.*

Under these circumstances the avoidance of unnecessary damage to the ureter is of prime importance and its identification, unless aided by artificial means, is a matter of no small difficulty and considerably lengthens the time of operation. We have believed it best to isolate the ureter on one or both sides, according as the pouch was unilateral or bilateral, in the neighborhood of the iliac vessels. The ureter is then clamped lightly with a Crile clamp to prevent wound contamination by the urine, opened and a good sized gum-elastic bougie passed to the bladder and left in place. This maneuver renders the identification of the ureter easy at all times and removes the danger of its accidental incision or division. The difficulty next met with is the separation of the pouch from the surrounding tissues, to which it is generally firmly welded. It has generally seemed unwise to split the bladder wall down to the orifice, as is done in the posterior or high lateral wall cases, and particularly is this undesirable in bilateral diverticula. The separation of the sac is in some cases much facilitated by packing it with gauze, thus giving a firm mass on which to dissect and rendering the identification of the tissue easy. Our greatest difficulty has lain in the

fact that these pouches are so surrounded by scar tissue and glued to everything in the neighborhood that it is by no means easy to distinguish them from other important structures, as for instance, the rectum. After the pouch has been thoroughly freed (it generally must be done with the scissors and cannot be freed by blunt dissection) it may be drawn upwards by means of a clamp and the neck of the sac freely divided. The wound thus left can generally be closed without difficulty, though in the cases situated below the ureteral orifice the adherence of the bladder wall to surrounding structures sometimes makes closure without tension difficult.

The hardest problem lies in those cases in which the orifice of the ureter has been drawn upward into the diverticulum. For these, Young some years ago suggested a technic which involved the leaving of a flap of bladder wall around the ureteral orifice, the rest of the sac having been excised. This flap was to be sutured into the defect in the bladder wall. This technic is ideal and I am glad to be able to report that I have recently carried it out without serious technical difficulties and I believe with a good result. This flap should have its base toward the median line, not only because of the probably better blood supply, but because in the majority of cases these sacs lie above, below or to the outer side, and much more rarely to the inner side of the ureter. From these anatomical peculiarities it follows that the ureter naturally tends to follow the inner side of the sac. Where this technic is to be carried out it is essential to have a guide in the ureter, but, as I have already pointed out, I believe this to be desirable in any case. Where the conditions are such that the technic of Young is impracticable and the ureter yet enters into the diverticulum, it must of course, be divided and reimplanted into the bladder wall at a point which can be reached wholly without tension. We have come to believe, largely by experience in other conditions, particularly cancer of the bladder, that the most successful implantations of the ureter are accomplished by leaving a half inch or more of the end of the ureter projecting into the bladder. The intent of this is to enable the ureter to accommodate itself to the altering conditions of the bladder and finally come to rest without tension. We have not believed that it was desirable to attach the ureter to the bladder wall by many sutures and have rarely used more than two for this purpose.

Drainage of the Ureter. The only further question is as to the desirability of providing drainage for these dilated and necessarily more or less abused ureters. In two or three cases we have placed a good-sized soft rubber catheter in the ureter, extending upward nearly to the renal pelvis, and have brought this catheter out through the suprapubic wound. The smooth convalescence of these patients suggests that this may be a desirable maneuver, and in a considerable number of cases in which constant drain-

age of the ureter has been employed for other reasons, no undesirable results have been seen. This I believe to be better technic than to drain the ureter through the incision made for the insertion of the guide bougie, and this incision we have always closed tightly with two layers, a technic which the dilatation of the ureter will always permit.

In conclusion I desire only to emphasize what seem to me the important points of the operative treatment of these cases: Free bladder incisions carried down to the orifice of the sac in the more accessible cases. The opening of the ureter and the placing of a guide bougie in all cases where the diverticulum is in the neighborhood of a ureteral orifice, and finally, the constant drainage of the ureter for some days in those cases in which resection has been necessary or the flap operation of Young has been possible.

SPLENIC ANEMIA WITH REPORT OF A CASE.

By P. E. TRUESDALE, M.D., FALL RIVER, MASS.

D. H., female, aged 21. American born. Good family history. Admitted to the Highland Hospital, January 11, 1912. Referred by Dr. W. T. Learned. She had "anemia" at seven years, otherwise no illness of importance. For five years she had indigestion, frequently demanding enforced rest and the exercise of special care in her diet. Attacks of hematemesis occurred at least as often as once a year. Stools were always "tarry before an attack." Epigastric pain during the second attack was severe and tenderness across the upper abdomen subsided only after many days.

Catamenia began at 16. Though irregular for several years it has been regular during the past year. Accompanying discomforts have not been marked. About November 20, 1911, she noticed that her stools were tarry. A few days later she vomited blood. Hemorrhages continued for about five days and she remained in bed two weeks. During this attack there was acute pain in the epigastrium with local tenderness that was quite marked. Her best weight was 138 pounds in November, 1911. When this attack subsided she was hungry between meals, but had no pain.

Physical Examination. Well developed and nourished girl, perceptibly anemic. Throat was negative. Heart of normal size and position with sounds regular and of fair quality. Over the precordia there was a loud blowing systolic murmur, heard best at the base and along the left border of the sternum. Palpation of the abdomen revealed an enlargement of the spleen, the lower margin of which was about half way between the costal margin and the umbilicus.

Examination of test meal showed HCl-10. Total acidity=30. No bacteria. No blood or pus cells.

The blood examination was as follows:

Jan. 12, 1912.

Red cells	2,400,000
White cells	3,800

Hemoglobin	30%
Color index62

Smears: No normoblasts; no megaloblasts. The red cells show variation in size, but not to a marked degree.

Jan. 16, 1912.

White cells	3,000
Differential count of 100 white cells	
Polynuclears	78%
Lymphocytes	14%
Myelocytes	4%
Eosinophiles	4%

Jan. 27, 1912.

Red cells	3,800,000
White cells	2,200
Hemoglobin	45%

On January 31, 1912, laparotomy was done with a view to splenectomy. Dense adhesions from the spleen to the parietal peritoneum were encountered. Upon separating these adhesions there was persistent hemorrhage of a degree which soon made itself apparent in the condition of the patient. The spleen was, therefore, not removed. The peritoneal covering of the spleen was divided in several places and the omentum was anchored high, with a view to establishing a collateral circulation. The abdomen was then closed. There was a good recovery following this operation and the general condition of the patient continued fairly satisfactorily until November, 1912, when she had another attack of hematemesis.

Examination of blood, April 21, 1913, was as follows:

Red cells	4,800,000
White cells	4,000
Hemoglobin	80%

She entered the hospital again on April 22, 1913. Splenectomy was done. The collateral circulation, which had resulted from an interposition of the omentum, was essentially with the vessels of the abdominal wall. Smart hemorrhage took place from these enlarged omental veins, which, however, were accessible and quickly controlled. There was no excess of free fluid in the peritoneal cavity. Although the spleen was a good fraction larger than it was when seen before, its delivery appeared to be less prohibitive. The liver was more grayish, but its surface was smooth and its consistency apparently normal. The spleen was "turned turtle," as described by Warren,¹ and the large vessels at its hilum were ligated. The operation was completed with the patient in fair condition. Convalescence was slow, but was marked by a progressive improvement in the blood picture, and in the general health of the patient. Now, eighteen months after operation she has passed her probationary period in a training school for nurses connected with the hospital of a neighboring city.

Blood examinations at the date of discharge from the hospital and subsequently were as follows:

May 4, 1913.

White cells	10,000
-------------------	--------

May 13, 1913.

White cells	15,000
Red cells	4,800,000
Hemoglobin	70%

May 28, 1913.

White cells	10,000
Red cells	4,000,000
Hemoglobin	80%

January 1, 1915.

White cells	12,000
Red cells	5,600,000
Hemoglobin	85%

Pathological Report. Specimen consists of a spleen weighing 288,000 grams. It measures 21 x 13 x 7 cm. At the lower pole there is a patch of calcareous deposit, 7 x 4 x 5 cm.

Microscopical Examinations. Sections of the specimen show the increase in size to be due to an overgrowth of the connective tissue of the organ. There is no hyperplasia of the lymphoid tissue. Some sections are densely peppered with a black pigment (iron?).

Diagnosis. Chronic splenitis

DR. A. C. MACRAE.

This case is recorded on account of its clinical analogy to gastric ulcer. The patient had a persistent disturbance of digestion, hunger between meals, intermittent attacks of hematemesis and epigastric tenderness. During one attack she was seen by Dr. W. T. Learned and Dr. E. F. Curry, whose examination revealed an elevation of temperature and pulse, associated with a distention and marked tenderness over the upper abdomen. The cause of this picture, by no means inconsistent with a perforated gastric ulcer spontaneously sealed, was explained by the presence on the upper surface of the spleen of a large area that had become necrotic. Later, upon finding an enlargement of the spleen, a blood examination was made and the diagnosis established. Thus is emphasized the indispensability of a blood picture in a case in which the spleen may be suspected of playing a part.

Splenic anemia occurs in young adults as a rule. It begins insidiously and at first progresses slowly. The first indication may be hematemesis, epistaxis, melaena, slight or so severe as to be almost fatal. Senator² states that the blood examination reveals a fairly uniform condition of things. There is a diminution in the red blood cells. There is a low percentage of hemoglobin, and a leucopenia. In the later stages of the disease ascites appears, preceded or not by cirrhosis of the liver. It is this association of enlarged spleen, ascites, and cirrhosis of the liver to which Banti³ has drawn special attention. He pointed out that in cases of this association the enlargement of the spleen, sometimes at least, was the precursor of the other two conditions and probably was the original focus.

D'Espine⁴ believes that the beginning of Banti's disease in adults dates from early child-

hood in many cases. He reports two cases in infants with the autopsy findings and tabulates the details of sixteen other cases in children which he has compiled from the literature. In eight cases the symptoms were merely enlargement of the spleen and anemia,—the first stage; in seven cases there were in addition hemorrhages, especially from the stomach and intestines, urobilinuria, slight jaundice and ascites. D'Espine inoculated the spleen tissue into animals with negative results, confirming the belief that the disease is not of infectious origin.

L. B. Wilson,⁵ in a study of eighteen cases of splenic anemia at the Mayo Clinic, writes on the pathology. Thirteen spleens examined showed a chronic diffuse process. In each spleen there was hyperplasia of one or more of the constituent elements. He further states that, while primary splenomegaly may begin as an overgrowth of the lymphoid tissue or of the endothelium, in the ordinary course of events a secondary overgrowth of the stroma of the glands will appear later, accompanied by a degeneration of the lymphoid or endothelial elements; that the largest spleens are those in which the lymphoid or endothelial hyperplasia is greatest. Wilson concludes by observing that the histological picture from cases of primary splenic anemia seems always to be in complete harmony with the hypothesis of the presence of a slowly acting local toxin.

Splenic anemia is now claimed by many authors to have found its place among curable diseases. Present interest appears to be centered around an obscure etiology and the end results reported after splenectomy. Reports of splenectomy for this affection are no longer rare in literature, yet few were to be found published prior to the last decade. The disease was not regarded a clinical entity and the mortality from surgical measures was high, 28%, for example, in a series of 32 cases reported by Armstrong.⁶ D'Espine⁴ reported eight cases in which splenectomy was done, with recovery of all but one of the children. Among the early successful splenectomies for splenic anemia was a case reported by Dr. J. Collins Warren.⁴ The patient was a male, aged 26 years, who complained essentially of distress after eating, occasional vomiting and a troublesome diarrhea. The diagnosis was made from the blood picture and the presence of an enlarged spleen. The operation was complicated by considerable hemorrhage, which was effectively controlled by turning the spleen over in a downward direction, thereby delivering the large vessels of the hilum of the spleen well into the abdominal incision.

Inasmuch as this case was among the first splenectomies for splenic anemia, the details of his tory leading up to his death form an interesting report. With the assistance of Dr. Warren of Boston and Dr. Torrey of Beverly, he was traced to Greensboro, N. C. By the courtesy of Dr. John Wesley Long, who attended him there, the following report is available.

J. M. entered St. Leo's Hospital, Greensboro, N.C., December 21, 1912. He had not worked for two months on account of nausea, spitting and vomiting of dark fluid. He denied having indigestion or abdominal pain. He stated that he was otherwise as well as usual though not as strong. On the morning of December 20, 1912, while in his berth on the train, he was seized with vomiting and was found on the floor of the sleeper in an unconscious condition, having vomited much bloody fluid. Soon after his admission to St. Leo's Hospital he had another severe spell of vomiting dark bloody fluid. When seen by Dr. Long on the following morning the patient was conscious, much prostrated, pale and inclined to sleep. The pulse was rapid and weak. Attacks of hematemesis continued to recur. The blood picture was as follows:

Red corpuscles	1,936,000
Leucocytes	16,000
Hemoglobin	40%

The patient was losing rapidly and after a consultation it was deemed advisable to operate. The following note was made at the time of operation. The stomach was opened through a 3-inch incision, near the pylorus. The stomach contained bile-stained bloody fluid. No ulcer or growth was found. The pylorus was patulous, and the duodenum dilated but contained no ulcer as far as explored by the finger and the eye. The duodenum and jejunum appeared to contain many blood clots. The under surface of the liver, especially about the bile ducts, and also the left lobe of the liver were hard and nodular, not quite the woody hardness found in malignancy. A small section was removed from the liver for examination. Following the operation the patient had no nausea or vomiting but during the afternoon had a copious bowel movement consisting largely of blood clots, soon after which he succumbed. The excised piece of liver was sent to Dr. W. T. Whitney, curator of the Warren Anatomical Museum, who reported that it was undoubtedly cirrhosis.

Klemperer and Mutsem⁷ report a case of Banti's disease cured by splenectomy. Urbino⁸ reports nine splenectomies for anemia, from Nucci's clinic with three deaths. W. J. Mayo⁹ reports eighteen splenectomies for splenic anemia with two operative deaths and twelve that are well twelve months to seven years after operation.

In conclusion one may reiterate the importance of a blood examination in conjunction with other evidence in order to differentiate splenic anemia from a type of gastric ulcer occasionally present in young adults. And that a patient restored to health for many years by splenectomy may die from a probable continuation of the same process of intoxication.

THE STUDY OF DISTURBANCES OF THE STOMACH.

By H. F. HEWES, M.D., BOSTON.

[From the Clinic of the Massachusetts General Hospital.]

(Continued from page 341.)

The record so far gives us a diagnosis of chronic gastritis proven by the tube finding. This condition may exist by itself or be an associate of cancer. The absence of blood here was perhaps in favor of a simple gastritis as against cancer, but cancer gastritis does not always show blood. The history of alcoholism gave a sufficient explanation of the gastritis. An x-ray examination was made as a further possible means of investigating the possibility of cancer. The x-ray finding was negative. Of course a negative x-ray finding does not rule out cancer, but after exhausting all methods and finding evidence of gastritis only, we are justified in a diagnosis of simple gastritis.

This same result is true in cases where the result of tube examination and x-ray examination are both negative, whatever the character of the history in cases of nervous dyspepsia, and debility, or in cases where the tube finding shows simple hypersecretion or hyperacidity with negative x-ray findings. Some of these cases may be conditions of organic disease but all that we can do is to exhaust our methods of study and report them as nerve or functional conditions according to the finding. In this case, the tube finding was the important factor in diagnosis.

This series of cases illustrates the method of procedure employed in stomach work. Diagnosis is made, as you see, sometimes on the evidence of one finding, but as a rule by the study of the combined evidence of the findings by all methods of study, the history record, tube examination, and x-ray examination. A very important factor is the judgment of the physician in interpreting the evidence of the combined clinical picture. A physician may be expert in tube examination or in x-ray examination, but this is not enough. Most of all he must be a man of experience in the interpretation of combined clinical pictures.

The meaning of special findings, however definite, varies greatly according to the other factors of the case. Thus a definite x-ray finding has one meaning when combined with one kind of history or one kind of tube finding, and another meaning when combined with a different record in this respect.

This point is illustrated by the following records:

CASE 10. M., age 20. For eight years, probably more he thinks, he has had spells of dyspepsia, consisting of distress in lower part of epigastrium, coming on two hours or more after meals. The symptom comes three times a day and is relieved by eat-

ing. Has 2-4 spells a year, lasting until he consults a doctor, then freedom for about two months, then another spell. No vomiting, some gas. The principal thing is a gnawing distress in belly. Is otherwise a well boy.

Examination: Hb., 100%. Physical examination negative.

Fasting contents, 20 c.c. of clear fluid containing a few cells, no food, no blood. Feces negative.

X-ray: Stomach outline normal, good sphincter, but irregularity of D-cap. Marked deep vigorous peristalsis in stomach above pylorus. No 6-hour residue.

Diagnosis: History suggests a duodenal ulcer of long duration. X-ray suggests duodenal ulcer. Operation: Small ulcer of anterior wall of duodenum with scar tissue.

CASE 11. E. Z., age 22, Aug. 5, 1914. For ten years at least has had trouble with his stomach, he calls it sour stomach. He will have 2-3 days of symptoms, then freedom for perhaps a week. Mostly the symptoms in the spells consist of distress soon after eating, which may last hours. There is gas and sometimes vomiting. The location of pain is just below the navel, on the whole to the right,—it is not really pain, but distress and a sour feeling in the mouth, with raising of acid fluid. For a period of two years vomited often, every 2-3 days, after food. No vomiting now. Trouble may keep him from work in spells. Bowels always constipated.

Examination: Physical examination negative. Fasting contents, 20 c.c. of clear fluid with abnormal cellular sediment but no food. Free HCl present. Test meal: Free HCl, 0.15%. X-ray record: Constant irregularity of duodenal cap. Outline of stomach normal, sphincter normal. Stomach empties at the start more quickly than normal, yet some 6-hour residue. Peristalsis above pylorus normal.

Diagnosis: History suggests some longstanding cause of dyspepsia, but the type of symptomatology is not typical of ulcer, though possible as an associate of this condition, since many ulcer cases do not have typical symptomatology. X-ray finding suggests duodenal ulcer, in the irregularity of the duodenal cap area by fluoroscope and plate, similar to that seen in the patient just reported who was operated upon the day before this patient and showed duodenal ulcer.

Operation: No ulcer or abnormality of stomach or duodenum formed. Chronic appendix with mass of adhesion about it. Appendix removed and diagnosis verified.

Here are two cases with a similar x-ray finding of a significant character in the present state of knowledge of x-ray interpretation. In the case with the ulcer, the history record was typical also, and I had no hesitation in making a positive diagnosis. In the second case the history was not typical and I did not make a positive diagnosis, but thought the x-ray finding sufficiently definite to justify exploration, especially with the long history of disturbance. There is one more point brought out by a comparison of these two cases. The x-ray expert made a positive diagnosis of ulcer in both cases but he pointed out a discrepancy in the second record as contrasted with the first which makes

the record less typical as regards ulcer than the first. In the first case in addition to the constant irregularity of the duodenal cap there was abnormally deep and vigorous peristalsis of the stomach. In the second there was the same irregularity of the cap but the peristalsis of the stomach was normal. On such points, a difference in associated symptoms with similar findings by x-ray, and a slight variation in these x-ray findings in the two cases, may a difference in diagnosis hang.

CASE 12. R. T., age 28. May 12, 1912, the patient was operated on for appendicitis. The attack as far as could be determined was an acute one and some fluid was found in the peritoneal cavity. Six months after the operation the patient began to have symptoms of stomach distress, which have continued since and increased in severity. At the present time, Sept. 1, 1914, the symptoms are as follows: Upon rising the patient is all right and eats a good breakfast. About one hour after breakfast a gnawing feeling comes in his stomach and he begins to regurgitate sour stuff, which he spits out. The noon meal relieves the symptoms. One to two hours later they begin again—to be again relieved by the evening meal, returning about 9 p.m. No vomiting. Some loss of weight. The trouble is always with him.

Tube examination: Fasting contents, 20 c.c. of clear fluid. No food, no blood, free HCl present. Test meal contents: Free HCl, 0.19%; high acidity. Feces examination negative. X-ray examination: Marked irregularity of pyloric sphincter and duodenal cap. Peristalsis above abnormally deep and vigorous. Operation showed firm bands of adhesion running from the duodenum to the gall bladder and liver. Many adhesions about gall-bladder and about cecum and ascending colon at hepatic flexure. Gall bladder normal. No evidence of ulcer of the stomach or duodenum.

If we compare the record of this case with that in No. 10 which proved to be a case of duodenal ulcer, we find that the two records are similar in all respects, the character of the symptoms, the tube finding and the x-ray finding. Even the minute details of the x-ray finding are similar. In fact the x-ray expert made a positive diagnosis of duodenal ulcer in Case 12 as well as in Case 10. The only difference in the two cases lies in the record of appendicitis and operation preceding the onset of symptoms in the latter case. This one point of the record suggested that adhesions formed at the time of the appendicitis and attached to the duodenum might be a pathological process behind the symptoms rather than ulcer. In fact this was the diagnosis which was made before operation in spite of the x-ray expert's diagnosis of ulcer.

Adhesions are an undoubted cause of stomach symptoms in many cases. As a rule they do not give as typical a picture of duodenal ulcer in history and x-ray findings as in this case, but this case and many other similar ones that I have seen prove that they may do so. So where there is reason from the earlier record of the

case, to believe in the presence of adhesions, as in this case, I always make an alternative diagnosis of ulcer or adhesions, or cancer or adhesions, whatever the x-ray sign, unless the tube findings prove definitely cancer or ulcer.

Here is another case illustrating this same point, viz:

1. The capacity of adhesions to give stomach symptoms. 2. To give x-ray findings which cannot be distinguished from the findings seen in cancer or ulcer of the stomach. 3. As compared with the cases already reported, the different meaning of definite x-ray findings when associated with one set of clinical factors, from that seen with the same finding associated with another set of clinical factors.

CASE 13. M. S., age 60. Two years ago the patient was taken with a sharp pain in the epigastrium to the right, going to the shoulder blade. Pain lasted 4-5 hours. Patient was then well, with no symptoms of dyspepsia for six months, when another attack of pain in the stomach and right side occurred. The severe pain lasted most of one day, and some pain continued for three weeks. Was laid up in bed. No vomiting. Then relief until five months ago, when pain again returned. This pain has been present ever since, not constantly, but a part of every day. Some gas. Bowels constipated. The patient has developed a brown color. The distribution is not that of Addison's disease. No real icterus.

Examination: Hemoglobin, 70%. Physical examination negative. Fasting contents: 10 c.c., no food, no blood, no excess of cells. Free HCl present. Test meal: Free HCl, 0.07%.

X-ray examination: Failure of peristalsis over lower part of curvature and antrum. An irregular shadow in this region. Some 6-hour residue of bismuth. Sphincter and cap normal. Diagnosis: History suggests gall stones. X-Ray record, carcinoma of the stomach. Tube finding against cancer of the stomach advanced sufficiently to give the x-ray picture obtained, if this picture represented cancer.

Operation showed gall stones, and firm adhesions from gall bladder to curvature of stomach and duodenum. Here we had an x-ray finding suggesting malignant disease of the stomach or at least some lesion of the stomach wall, but the distortion of the stomach was due to adhesions.

This case, like the others, shows how much diagnosis may be a matter of the evidence of the combined findings of the case, rather than of any one single finding however positive.

From the practical point of view in such cases as these, doubt as to the exact diagnosis, or error in this, is not of great consequence, since all the cases had an organic lesion, for which operation was the proper treatment. All that we needed to diagnose was some organic pathological process affecting the stomach, demanding operative treatment, ulcer, or cancer, or adhesions. The cases where we cannot afford to make such positive diagnosis incorrectly are those where the stomach condition, giving the

positive signs as the x-ray signs, is a purely functional process or the result of reflex disturbance of the stomach from general disease, or from disease located elsewhere than in the stomach or stomach region. A case of gall stones can be operated upon through the same opening made for stomach exploration, but a case of chronic appendix (Case 2) or of intestinal adhesion, or a renal calculus cannot always, and in such cases the error is of some account, even if real operative work is needed after all, and the functional conditions, nerve conditions, heart conditions, tubercular conditions, syphilitic conditions, ptotic conditions, giving stomach symptoms or signs, should not be opened at all.

Here is another case illustrating this same point of the dependence of diagnosis upon combined findings rather than one single finding.

CASE 14. R. H., age 42. For 2½ years the patient has suffered much of the time from distress soon after food and bloating with gas. Eight months ago she began to vomit and has vomited every day since, sometimes three times a day. Vomiting comes after eating, and according to the patient contains food of previous days. No actual pain. She has never vomited blood. The patient has lost about 10 lbs. in 8 months. She is evidently of neurotic type.

Examination: Hemoglobin, 80%. Examination otherwise negative.

Tube examination: No fasting contents obtained. Test meal contents. Free HCl, 0.18%.

X-Ray examination: Opposite lesser curvature an incisura. No other irregularity in stomach outline. Peristalsis vigorous. Feces showed slight blood test. The x-ray finding here was suggestive of possible ulcer but not definitely diagnostic as the peristaltic variation from normal was slight and such as may be seen in functional disturbance or with adhesions. Further tube examination and feces examination was ordered. The second tube examination showed: Fasting contents 15 c. c. of reddish fluid giving a strong blood test, no food, free HCl present. Numerous epithelial cells in sediment. Test meal contents taken a day later gave a positive blood test. Feces gave a positive blood test. A third tube examination gave a positive blood finding in the fasting contents. Feces again gave a blood test. A second x-ray examination gave a normal finding. The incisura found before could not be seen.

With the repeated blood findings, however, it was decided to explore for ulcer. Operation showed a chronic ulcer of lesser curvature. In this case the x-ray finding was suggestive of ulcer on one occasion but failed to give evidence on another. It was not conclusive enough to go by alone, but with the repeated blood findings in the stomach contents and feces, and the history, the combined picture was sufficient for diagnosis of ulcer. In fact, I should have advised operation here upon the repeated blood findings alone, if both x-ray records had been negative.

CASE 15. R. P., age 25. Two years ago the patient had a sharp attack of pain in the epigastrium followed by several days of dyspepsia. No vomiting. Since that time there have been several periods of dyspepsia lasting a week to a month with gnawing distress, coming as a rule one to three hours after eating, and raising of gas. For the last two months dyspepsia has been fairly constant.

Examination: Hemoglobin, 85%. Physical examination otherwise negative.

Tube examination: Fasting contents, 20 c.c. of clear fluid, no food, no blood, free HCl present. Test meal contents. Free HCl, 0.07%. Feeces examination negative.

X-Ray examination: Incisura in antrum wall. Peristalsis vigorous on lesser curvature. X-Ray diagnosis, ulcer of lesser curvature near antrum. With this finding further tube examinations were ordered. All of them were negative as well as all feces examinations. The patient was operated upon with the diagnosis of gall stones, in spite of the x-ray diagnosis of ulcer. Gall-stones and some adhesions from gall-bladder to stomach were found. Here the incisura x-ray finding was not supported by tube findings as in the previous case, and it meant a different condition than in the previous case, though similar in type.

Definite tube findings also have a different interpretation according to the associate findings. For example, a hypersecretion or hyperacidity finding combined with an x-ray finding suggesting gastric duodenal ulcer, means ulcer. In the absence of such associated finding it may mean simple hyperacidity.

There are a few facts which I have had impressed upon me by experience in the study of stomach cases, which I wish to specially emphasize. The first fact is the danger in making a diagnosis by the record of symptoms alone in the face of negative tube, x-ray and feces findings, particularly if the diagnosis leads to advice for operation. The following case will illustrate this point:

CASE 16. A. R. Age 50. August 1914. One year ago the patient began to have distress in the stomach coming soon after meals and associated with vomiting from the start. The distress came daily, the vomiting three or four times a week in the early days. The condition has persisted. During the last month vomiting has occurred daily. No blood seen. The patient has lost 25 lbs. in weight in four months.

Examination: Patient thin but fairly nourished. Hemoglobin, 75%.

Tube examination: Fasting contents, 20 c.c. of clear fluid. No food, no blood. Free HCl present. Test meal contents. Free HCl, 0.06%. X-ray examination. Outline of stomach and duodenum normal. Peristalsis normal. Feeces test negative.

Here the history suggested marked stomach trouble as in Case 2, but all clinical findings were normal. A diagnosis of possible cancer was made by the attending physician and operation was performed. No lesion of the stomach was found. Gall bladder and appendix were also normal.

This case illustrates the danger of positive

diagnosis by history alone, with negative clinical findings. I was personally against operation in this case as I did not believe that either cancer or ulcer of the stomach capable of giving the symptoms recorded here could exist with negative findings both by x-ray and tube.

Here is another case showing the unreliability of a record of subjective symptoms for diagnosis:

CASE 17. R.A., Age 29. For two years the patient has suffered from dyspepsia continuously. The symptoms are distress coming one to three hours after meals, relieved by food, frequent regurgitation of sour fluid, no vomiting. Loss of 20 pounds in two years. The patient is a steady drinker but never gets drunk.

Examination: Hemoglobin 90%. Fasting contents, 50 c.c. of green mucus like fluid adhesive to the bowl. No food, no blood, no free HCl. The sediment is filled with epithelial cells in mucus. Test meal. Free HCl present, amount 0.03%, lower than the average normal. Feeces examination negative.

(To be continued.)

A STUDY OF THE EFFICIENCY OF MIXED TOXINS (COLEY) IN INOPERABLE SARCOMA. A CRITICAL ANALYSIS OF 134 MICROSCOPICALLY PROVEN CASES.

By TORR WAGNER HARMER, M.D., BOSTON.

Assistant in Anatomy, Harvard Medical School; Junior Assistant Surgeon, Children's Hospital; Assistant in Surgery, Massachusetts General Hospital.

(Continued from page 335.)

CASE REPORTS.

INTRAXASAL AND ACCESSORY SINUSES.

CASE 6. Personal Case. E. M. McK., girl of 12. Throat records, vol. xv, p. 161. Referred by Dr. Mosher.

Feb. 17 1911, record states: right incisor stands alone pushed out in front of tooth line. Gum on this side very much enlarged and darker in color than surrounding tissue. Both antra dark to transillumination.

Feb. 18, 1911. Operation, Dr. Mosher. Ether. Right upper canine removed and found to be sound. Tumor tissue hard and fibrous, slightly suggestive of osteosarcoma. This was found to extend upwards into antrum. The anterior wall of the antrum together with tumor removed with chisel. Cavity curetted. Considerable hemorrhage. Packed.

Pathological Report. Giant cell sarcoma.

March 1, 1911. Toxin treatment started and continued for six weeks. Maximum dose, 2½ minims. Constitutional reactions of moderate character. Local reactions (pain in cavity after injections) severe.

March 4, 1914, two years, eleven months since toxins discontinued, patient found in her new home. Well developed and nourished girl of good color

without subjective or objective evidence of recurrence.

May 29, 1914. Patient still well, three years, one month since treatment discontinued.

Criticism. Owing to the good results obtained by excision and curetting in cases of this type it may be argued that this case should be excluded. It has been included on account of the size and extent of the process. Recorded in Group F.

CASE 7. Personal Case. Referred by Dr. Mosher. Chondrosarcoma of the antrum, ethmoid, and sphenoidal sinuses. J. T., a weaver of 31. Throat records, vol. xxiii, pp. 41 and 255.

Nov. 11, 1912. Ten weeks ago struck over left zygoma with weaving shuttle. Swelling persisted and after two weeks began increasing. Slight exophthalmus for six weeks. Pain slight. Examination shows considerable edema of the left face. Tenderness to pressure over zygoma and antrum with dense shadow of all sinuses on the left by transillumination.

Nov. 12. Operation, Dr. Mosher. Zygomatic arch removed, exposing somewhat encapsulated tumor involving antrum, ethmoid and sphenoidal sinuses. Removed as completely as possible with the curette and packed.

In four days mixed toxin treatment begun and continued every other day for five weeks. Injections into abdomen with marked systemic and very marked local reactions. Maximum dose, 16 minims. No evidence of recurrence upon discharge (Dec. 24).

Pathological Report (1211-59), Dr. W. F. Whitney. Chondrosarcoma. Small piece of firm fibrous looking tissue. Microscopical examination showed growth of small cells in rather solid masses, in places with a hyaline degeneration, and in other places a myxomatous character, in still other places an appearance suggesting softened cartilage.

Two months later returned with recurrence size of walnut below left eye. Dr. Mosher performed an extensive operation, removing part of the superior maxilla. Nine months later in good flesh and color without evidence of recurrence. A few months later, however, an extensive recurrence developed involving the orbit and patient died. Recorded in Group C.

CASE 8. (Table, Case No. 4.) Case of Dr. L. L. McArthur of Chicago. Female, age 5½ years. Sarcoma of antrum and naso-pharynx.

Pathological Report. Round cell. Toxin treatment instituted and continued three months with disappearance of growth; but this recurred in a few months and proved fatal. Recorded in Group C.

TONSIL.

CASE 9. (Case No. 13.) Round cell sarcoma of the tonsil and neck. C. W., male, age 56 years. Growths of the right tonsil and neck for two months about size of an almond and English walnut respectively. Toxin treatment continued three months. Maximum dose, 5 minims. Reactions fairly severe. Tumors began to decrease in size after first week, became softer and more movable and disappeared in five weeks. Site of injections pectoral region. No recurrence 3½ years later. Recorded in Group F.

CASE 10. (Case No. 4.) Round cell sarcoma of tonsil and neck. A. L., female, 11 years of age. Growth of right tonsil and neck of a year's duration, size of half an egg. Toxin treatment continued six months with marked softening and entire disappearance in two months. Maximum dose 3 minims. Reactions marked. Injections into pectoral region and a few into neck. Well six years, seven months after toxins discontinued. Recorded in Group F.

CASE 11. (Case No. 3.) Small round cell sarcoma of the tonsil and neck. H. M., male, 32 years of age. A growth of two weeks' duration, involving tonsil and neck, was operated upon but speedily recurred despite x-ray and radium treatment. Pathological report of recurrence, a small round cell sarcoma. Toxin treatment for about seven weeks. Reactions marked. Growths entirely disappeared in six weeks. Injections into tumor and pectoral region. Interval between operation and toxins six weeks. Recurrence in other tonsil five years later. Twice operated. Death in two months. Recorded in Group C.

CASE 12. (Table, No. 84 and *Surg., Gyn. and Obst.*, 1911, vol. xiii, pp. 184-5.) Case of Drs. Crile, McMullen, Stanton, and Coley. Male, 35 years of age. An inoperable small round cell sarcoma of the tonsil and neck. Toxins instituted with almost complete disappearance in five weeks. The dose was then reduced and in another five weeks the tonsil was of twice normal size. Second microscopic examination, round cell sarcoma. Toxins continued with entire disappearance of tumor. Doses again reduced, followed again by recurrence. Death one year after treatment started. Autopsy showed no metastases except in neck. Recorded in Group C.

CASE 13. (Case No. 14.) Small round cell sarcoma of tonsil with metastases in both sides of neck. C., male, 42 years of age. Growth of right tonsil nearly blocking up pharynx with masses in both necks. Toxins instituted with entire disappearance of growths in four months. Injections into pectoral region. Maximum dose, 20 minims. Reactions severe. One year later recurrence in submaxillary region, size of hen's egg. Removed.

Pathological Report. Small round cell sarcoma. Toxins refused. Rapid recurrence and death within a year. Recorded in Group C.

CASE 14. Personal Case. Referred by Drs. Mumford and Porter. J. H. K. House No. 177039. Fireman of 25. A large round cell sarcoma of the right tonsil, size of ping-pong ball, pushing uvula to left, and of the right neck, 6 x 5 inches.

Pathological Report. (117-52.) Dr. H. F. Hartwell. "A small bit of tissue removed from a tumor shows microscopically tumor cells infiltrating muscular tissue. The cells composing the tumor are large round with very faintly staining cytoplasm and having deep staining nuclei. There are numerous blood vessels which lie in close relation to the cells. Here and there are larger-sized cells with multiple nuclei, which are frequently superimposed. There are a number of mitotic figures."

Treatment with toxins from July 18 to August 15, 1911. Sixteen injections. Maximum dose 18 minims. During first three weeks marked diminution in the size of the tonsil tumor, which became very fluctuant. Tumor in the neck practically disappeared. After this, despite increasing doses with

severe reactions, the tumors increased rapidly in size and the patient died Sept. 14, 1911. Recorded in Group C.

CASE 15. Personal Case. Referred by Dr. Farrar Cobb. Recurrent small round cell of tonsil and neck. A. B., Italian of 65. House records, S.S. vol. cvi, p. 277.

Admitted Sept. 26, 1910, complaining of soreness of left tonsil for three weeks. Local physician said to have removed a "piece of wood" from this tonsil one week ago. This tonsil is now the size of an English walnut, hard, not especially tender, and without ulcerated areas. Olive-sized gland behind angle of left jaw, hard and adherent, and slightly tender. Small pea sized gland above clavicle. Sept. 29, Dr. Knowles snared large portion of tonsil and removed the rest by dissection.

Pathological Report (109-123), Dr. Whitney. Lymphosarcoma. Left tonsil enlarged to the size of a small plum, soft and extensively necrotic. Microscopic examination of piece showed a growth of small round cells of lymphoid character but without any distinct follicles, but in places clearly infiltrating between bundles of muscle fibres. In these were numerous mitotic figures.

Oct. 5. Operation, Dr. Cobb. Extensive dissection of neck for removal of mass with tying of lingual and fascial arteries.

Pathological Report (1010-24), Dr. Whitney. Malignant lymphoma. Mass of glandular tissue 4 x 2 cm., which had broken down and contained considerable necrotic material. Microscopic examination showed a growth of small lymphoid cells, which were seen to be infiltrating into the surrounding fibrous tissue. There was no normal structure of the lymph node. Recorded in Group B.

PHARYNX.

CASE 16. Personal Case. Referred by Dr. Beth Vincent Aug. 20, 1912. G. P. O.P.D., No. 124742. Italian, 47. There was a firm ulcerating mass occupying the right tonsil, floor of mouth, base of tongue, epiglottis, soft palate, and pharynx. Laryngoscopic examination impossible. He spoke only in a thick whisper and could eat only liquids and very soft solids, much of which came out through the nose. Several sections removed under cocaine.

Pathological Report (128-121), Dr. Hartwell. "Specimen consists of several pieces showing, on microscopic examination a richly cellular tumor composed of spindle cells which are arranged in narrow bands interlacing with one another and running in all directions. Spindle-cell sarcoma."

Mixed toxin treatment instituted and continued regularly for four and one-half months. Maximum dose, 10 minims. The mass softened and sloughed out cleanly. He gained in weight and color, was able to eat more food without losing any through nose, and could speak distinctly. Against advice he then insisted on returning to work. In five months he was a pale, emaciated man with metastases in the lung, neck, and belly, practically unable to eat or make self understood by speech. Died August 22, 1913. Recorded in Group C.

CASE 17. Personal Case. Referred by Dr. Crosby Greene. Round cell sarcoma of the pharynx and soft palate. M. M., male, 32. House No., 192357, 193196, 193673.

Nov. 17, 1913, admitted with history of swelling in

throat of two months' duration. For past fortnight pain in right ear and "noises" in both ears. Deglutition difficult. Some dyspnea. Some difficulty in opening mouth. A somewhat pale, well built man. Teeth poor. Nose and ears negative. In soft palate a little to right of mid-line a large, hard, bluish red tumor, extending down into region of right tonsil and back into nasopharynx. Wassermann reaction negative. Oct. 17. Tracheotomy and enucleation of the tumor by Dr. Greene.

Pathological Report (1311-85), Dr. Whitney. Lymphosarcoma. An irregular piece of soft mushy tissue. Microscopic examination shows growth of small cells about size of lymphoid ones but without any regular structure.

Mixed toxins started in eleven days and continued for four weeks. Maximum dose, 3 minims. Reactions occasionally severe. Injections into growth which rapidly recurred. No appreciable effect upon this or metastases in the neck, which soon developed. Jan 5, 1914, Dr. Green excised glands of neck. Pathological report, round cell sarcoma. Recurrence occurred within two weeks. Recorded in Group A.

CERVICAL GLANDS.

CASE 18. (Case No. 7.) P. K., male, 41 years of age. Mass size of hen's egg in submaxillary region, operated upon but complete removal impossible, the tumor having involved the muscles of the neck and periosteum of the lower jaw.

Pathological Report. Small round cell sarcoma. Toxin treatment for one year with entire disappearance in three months. No evidence of recurrence 4½ years later. Recorded in Group F.

CASE 19. (Coley, Table, Case No. 6.) Recurrent small round cell sarcoma of the cervical glands. A. P., 2 years 10 months of age. After two attempts at removal followed by recurrence toxin treatment was instituted, when there was a series of tumors extending from clavicle to mastoid and also involving the axilla. Treatment continued three months with complete disappearance of all growths. Patient well twelve years later. Recorded in Group F.

CASE 20. (Case No. 11.) Round cell sarcoma of the cervical glands. H. W., male. Growth in submaxillary region size of pecan had been enucleated, followed soon after by recurrence size of a cherry. This also removed, followed within a week by diffuse recurrence.

Pathological Report. Small round cell sarcoma. Toxins started and continued for three months. The submaxillary growth had then disappeared and the other glands had not increased in size. A third attempt at removal was made, but complete operation was impossible. Toxins therefore resumed and continued nine weeks. Maximum dose, 9 minims. No evidence of recurrence seven months later. Recorded in Group F.

CASE 21. (Table, Case No. 3.) Case of Major C. G. Spencer, Royal Army Medical Corps. Small round cell sarcoma of the cervical glands. Corporal M. M., 25 years of age. Mass in left neck of a year's duration, excised, with rapid recurrence.

Pathological Report. Lymphosarcoma. Second attempt then made but incomplete, the left side of neck being filled with masses of large glands. Tox-

ins instituted and carried out in two courses of thirty-four days and one month each. Maximum dose, 8 minims. Injections into tumors with well marked local reactions. Masses entirely disappeared in one month. No evidence of recurrence nine months after treatment discontinued. Recorded in Group F.

CASE 22. (Table, Case No. 111.) Case of M. E. Green. An adult male with small round cell sarcoma of the cervical glands four times recurrent. Toxin treatment then carried out for several months with entire disappearance of growth. Patient well over three years later. Recorded in Group F.

CASE 23. (Case No. 15.) Round cell sarcoma of the cervical glands. F. W., male, 58 years of age. Removal of mass in right neck the size of a small egg, with recurrence within a month. Toxins then started and continued for eleven months. Maximum dose, $4\frac{1}{2}$ minims. Reactions moderate. Tumors entirely disappeared and no evidence of recurrence four years and ten months after toxins discontinued. Recorded in Group F.

CASE 24. (Case No. 12.) Round cell sarcoma of neck. A physician. Excision of the mass in neck had been practised, followed rapidly by recurrence, which in a month had attained the size of a fist. Toxins were then started, injections being given into pectoral region, and continued for three months with progressive decrease in size and softening. Maximum dose 20 minims. Six months after toxins discontinued no evidence of recurrence. Recorded in Group F.

CASE 25. Personal Case. Referred by Dr. Farrar Cobb. Multiple small round cell sarcomata. M. C., housewife of 55. House No. 186421.

Dec. 7, 1912. Six months ago began to have severe frontal headaches. Four months ago small hard swelling on right side of nose near bridge, which has gradually and painlessly increased in size. Three months ago mass discovered in front of right ear, which has also gradually and painlessly grown. About the same time a mass appeared just above right clavicle and another in right neck. A vigorous, somewhat obese woman with mass size of cherry on right side of nose, boggy to firm consistency, and firmly fixed. In right parotid region mass extending from zygoma over angle of jaw into neck and forward to region of submaxillary gland. Behind right sterno-mastoid muscle several pea to bean sized glands. In front and behind left sterno-mastoid muscle, several small glands also palpable. In right supraclavicular region a firm and freely movable swelling the size of a pigeon's egg.

Excision of several glands for diagnosis.

Pathological Examination (1212-45), Dr. Whitney. A packet of enlarged lymph nodes with homogeneous section. Microscopical examination showed normal structure of lymph nodes lost and a growth of small lymph cells size of lymphoid ones with numerous mitotic figures. Considerable hemorrhage throughout growth. On the edge it was sharply circumscribed and a singular growth was found infiltrating the surrounding fat tissue.

Toxin treatment started Dec. 17 and continued every two or three days until Feb. 15, 1913 (2 months). Maximum dose, 13 minims. Reactions very severe. During the first month of treatment the mass in the right parotid region diminished

very markedly. The mass over the clavicle became smaller. The mass on nose became softer. Despite these results a growth was developing in left submaxillary region and, although attacked vigorously with toxins, was not affected but grew steadily in size. The mass in right neck, however, practically disappeared. Toxins omitted. X-ray instituted. Patient died with metastases in abdominal wall, chest, and both breasts, in four months. Recorded in Group D.

CASE 26. (Case No. 16.) Round cell sarcoma of neck. L., male. Attempted removal of lympho-sarcoma of the neck with recurrence.

Toxins started, and after two months tumor had disappeared. Toxins continued four months longer. During the last two months of this period a recurrence had appeared which soon produced metastases in the axilla and abdomen. Patient died within a year. Recorded in Group C.

CASE 27. (Table, Case No. 26.) Case of J. A. Moore of Helena, Montana. Round cell sarcoma of the cervical glands. Female, 31 years of age. In January, 1894, unfiltered toxin treatment started for multiple supraclavicular masses. Treatment continued one month with entire disappearance of growths. These, however, soon recurred. Recorded in Group C.

CASE 28. (Table, Case No. 104.) Case of Dr. G. H. Muller of Philadelphia. A male with inoperable recurrence of lympho-sarcoma of the neck one month after attempted removal. Toxin treatment resulted in complete recovery. Patient remained well for four years, when local recurrences and intra-abdominal metastases appeared. Recorded in Group C.

CASE 29. (Table, Case No. 16.) Small round cell sarcoma of neck. Case of Dr. J. Collins Warren (B. M. and S. J., 1896, cxxv, pp. 673-674.) 45 F. Attempted removal of growth of submaxillary region unsuccessful.

Pathological Report. Small round cell sarcoma. Recurrence in two weeks. Under unfiltered toxins for three months with marked reactions. Entire disappearance of growth. Recurrence in three months. Recorded in Group C.

CHEST WALL.

CASE 30. (Case No. 33.) Spindle cell sarcoma of left half of thoracic wall. S. C., female 16 years of age. Tumor had appeared in left scapula region four months previously, had grown rapidly frontwards to the sternum and measured thirteen inches in breadth and two inches in thickness in the most protuberant part.

Pathological Report of the specimen, spindle cell sarcoma. Toxin treatment was started and continued for four months; injections into tumor. Whole mass entirely disappeared in three months. Patient in good health with no evidence of recurrence nineteen years later. Recorded in Group F.

CASE 31. (Table, Case No. 28.) Case of W. H. Battle of London. Fibrosarcoma of the chest wall. Male, 30 years of age. Toxin treatment undertaken for extensive growth in the pectoral region with masses in axilla above and below clavicle. Treatment continued four months with "almost complete disappearance." Well one year later. Recorded in Group E.

BREAST.

CASE 32. (Case No. 58.) Inoperable spindle cell sarcoma of the breast and axilla. Toxin treatment instituted for mass size of orange in left breast. Adherent to deep parts and extended into axilla. Section removed for examination.

Pathological Report. Spindle cell sarcoma. Entirely disappeared after 78 injections. In good health without trace of recurrence 18 years later. Recorded in Group F.

CASE 33. (Case No. 54.) Recurrent angio-sarcoma of breast. A. C., 59, female. Thrice recurrent angio-sarcoma of breast. Toxin treatment instituted when mass extended laterally from sternum to anterior axillary line and from clavicle above nearly to costal margin below. It was fixed to chest wall, composed of markedly protuberant nodules and considerably ulcerated. Treatment continued eight months attended by softening and progressive diminution in size of tumor. Mass then excised. No pathological report given. Seen eight years later with fractured femur. No evidence of former trouble. Recorded in Group E.

CASE 34. (Case No. 53.) Small round cell sarcoma of breast. K., 22, female. Four operations had been followed by recurrence. Toxins started and shortly afterward a fifth operation was performed. Toxins continued for three months. Recurrence again evident and removed. Seven and one-half years later patient in good health with no sign of recurrence. Recorded in Group C.

ABDOMINAL WALL.

CASE 35. (Case No. 73.) Spindle cell sarcoma of abdominal wall. H. L. G., female. Exploratory operation showed a tumor of four months' duration to be inoperable. It involved the entire thickness of abdominal wall and some of bladder wall.

Pathological Report. Spindle cell sarcoma. Toxin treatment continued three months with entire disappearance of growth. Patient well 12 years 3 months later. Recorded in Group F.

CASE 36. (Case No. 57.) Spindle cell sarcoma of abdominal wall and pelvis. J. F., 16, female. Growth of abdominal wall 7 x 5 in., apparently involving entire thickness, attached to pelvis, and from symptoms and position evidently involving bladder. Section removed.

Pathological Report. Spindle cell sarcoma. Mixed toxin treatment for about 4 months with disappearance of growth and improved general condition. No recurrence 19 years 7 months later. Six years after toxin treatment patient developed primary lesion of syphilis, which was cured by appropriate treatment. Recorded in Group F.

CASE 37. (Case No. 64.) Spindle cell sarcoma of abdominal wall. M. S., 18, female. Tumor of several months' duration of abdominal wall proved upon exploratory laparotomy to be both intra- and extra-peritoneal, but not connected with abdominal organs.

Pathological Report. Spindle cell sarcoma. After 30 injections of filtered toxins tumor disappeared. Reactions mild. Maximum dose, 6 minims. Patient well and without recurrence 1½ years later. Recorded in Group F.

CASE 38. (Case No. 2, p. 138.) Spindle cell sarcoma of abdominal wall. Case of Major C. G. Spencer of Royal Army Medical Corps. Female, 53. Growth of suprapubic region extending from pubes to within 1½ inches of umbilicus and 3 inches broad. Section removed.

Pathological Report. Spindle cell sarcoma. Attempted excision followed by immediate recurrence. Toxin treatment for about 3 months started 17 days after operation. Maximum dose, 6 minims. Tumor disappeared. Patient well 5 years later. Recorded in Group F.

CASE 39. (Case No. 55.) Fibro-sarcoma of abdominal wall. E. G. L., 28, female. Exploratory laparotomy revealed inoperable growth.

Pathological Report. Fibro-sarcoma. The mass extended into the abdomen, filling the right lower quadrant. Toxins started two months later and continued for ten weeks with disappearance of mass. Seventeen years later an abdominal hysterectomy was performed for fibroids. The abdominal wall was found normal and no trace of sarcoma was seen in the abdomen. Two years later (19 years after toxin treatment) patient still well. Recorded in Group F.

CASE 40. (Table, Case No. 97.) Round cell sarcoma of the abdominal wall. Case of Dr. Paul Pilcher. Male, 55. An exploratory operation revealed an inoperable growth of the abdominal wall. Section removed.

Pathological Report. Round cell sarcoma. Toxin treatment for four months with gradual and complete disappearance of the tumor. Well one year later. Recorded in Group F.

(To be continued.)

Medical Progress.

PROGRESS IN BIOCHEMISTRY.

By A. EVERETT AUSTIN, M.D., BOSTON.

AMINO-ACIDS.

Abderhalden¹ has been able to discover amino-acids in blood and blood serum, and to identify some of them. Since the separation of such acids has been accomplished in various ways, there can be no doubt whatever that free amino-acids are present in the blood. The methods of isolation, many of which are original with Abderhalden, are described in full.

Cambridge² estimates the amino-acids in the urine of diabetics by determining the total free ammonia according to Folin's method and the ammonia plus amino-acids by Marfatti's method (Formol titration); the difference is the measure of the amino-acid ammonia. This can be utilized for treatment and prognosis of the disease. In mild cases of diabetes no amino-acids are found, in severe forms they may amount to 0.5 gram per day; often they disappear when

the food contains no protein. In other cases they do not, under which conditions the prognosis is much more unfavorable.

Labbe and Bith³ have estimated the amino-acids in the urine of 120 individuals and, based upon this, came to the conclusion that whenever the functions of the liver are impaired, there is an increase of these acids in the urine. This increase is always an indication of the insufficiency of the liver in metabolizing the ultimate products of protein disintegration. In diabetes, with disturbances of nutrition and acidosis, this increase is the rule. In all other diseases where the destruction of the body's protein is rapid, and those ferments which separate the amino from the carboxyl molecule are weakened (pneumonia, leukemia, cancer and typhoid), the amino-acids are always found in the urine in much greater quantities.

The ability of the animal mechanism fully to synthesize the component parts of the protein molecule, when fed to it as fully split amino-acids, has been shown by Berg and Cahn-Bronner⁴, who have shown that the liver cells of animals thus fed exhibit exactly the same droplets as those fed on unsplit protein. These droplets possess all the characteristics of unmodified protein and never appear when fat or carbohydrates are fed; thus they have been able to demonstrate by the totally new method (histologically) the same fact as has been shown by metabolic experiments, the full synthesis of amino-acid.

BLOOD SUGAR.

Bing and Jacobsen⁵, using the method of Bang, have made a large number of estimations of sugar in the blood of healthy individuals, as well as in that of those suffering from many varied diseases. They claim that blood sugar of the normal person varies from 0.06 to 0.12%, with an average of 0.1%. After the ingestion of 100 grams of sugar, healthy individuals may react by an increase in the percentage, or may not. This is also true of many after any kind of carbohydrate food. Persons suffering from renal disease invariably have a glycosuria, which does not depend upon the greater blood sugar present, but upon some unknown factor. In diabetes there is not only an increase in the blood sugar after food, but also while fasting. There is no direct relation between the blood and urine sugar. Glycosuria may occur without hyperglycemia, due undoubtedly to a renal influence. The estimation of the blood sugar is of great value in prognosis, since, if there is no increase of blood sugar, though sugar may be found in the urine, it is a favorable omen.

INTESTINAL PUTREFACTION.

Rodella⁶ has attempted, by experiments on small animals, to determine the toxicity of stools in case of intestinal disease. His method was

to make a suspension of a gram of feces in five c.c. of sterilized water and then inject the same into a rabbit hypodermatically. A control was first made of the stools of normal individuals, both adults and infants. It was found that one gram of feces from a healthy individual will not cause the death of a rabbit. On the contrary, when there existed intestinal catarrh, of whatever origin or grade, whether accompanied with constipation or diarrhea, a gram of the feces proved fatal within a few hours when injected. Some individual peculiarities were noted, as follows: The infant's stools proved much more toxic than those of the adult; the degree of intestinal putrefaction cannot always be told by the effect of the fecal suspension when injected, but one can always differentiate between pathological and bland cases; furthermore, it is possible to detect latent tuberculosis in this way much earlier than in any other manner; there is no relation between the toxicity of the stool and its putrefactive changes. Some with no putrefactive products (indol, skatol, etc.) are extremely toxic, and others charged with these products are not at all poisonous.

GALACTOSURIA.

The utilization of lactose in watery solution, according to the experiment of Draudt⁷ on dogs with an Eck fistula, is reduced to 58% and of galactose to 21%, the remainder appearing promptly in the urine. Hence the liver holds a special power of converting these sugars into glycogen, a trait not possessed by other tissues of the body. Therefore a galactosuria indicates a more or less extensive separation of the hepatic cells from the portal circulation. During this alimentary lactosuria and galactosuria the sugar content of the blood is found increased. Its clinical application in hepatic diseases has not yet been demonstrated by the author. On the contrary, Maliwa⁸ believes that galactosuria is dependent upon both the liver and the kidneys. The liver determines the concentration of galactose in the blood. When its sugar-converting power is disturbed, with a normal absorption in the intestine, the concentration in the blood rises above the limit to which the normal kidney is adjusted. When the liver is normal, then a disturbance in the eliminating function of the kidney may allow the galactose to pass through into the urine, when the concentration of the blood is still within the limit established for the normal kidney. The quantitative application of the galactose test for impaired liver function must always be employed according to Woerner and Reiss⁹. Galactose must be given in doses of 40 grams, and when 3 grams or more of this appears in the urine it demonstrates a pathological condition of the liver. One hundred grams of levulose, however, must be taken, when if more than 0.7 gram is eliminated, the same conclusion is justifiable.

CHOLESTERIN.

Much interest has been aroused in the peculiarities of the cholesterin metabolism, and Picard¹⁰ has shown that, during violent exercise, the amount of this in the blood serum may become increased or diminished, but that whatever change takes place the opposite extreme always occurs in the adrenal capsule, so that a reciprocal relation always exists in these two as to their cholesterin content. This work has been carried still further by Havers¹¹, who, by experimental evidence, has demonstrated that the bile becomes much richer in cholesterin during hypernutrition, especially when the excess is made up largely of protein and fat. By restriction of food, fever and pregnancy, the amount of cholesterin becomes much lessened. After the birth of a child, however, the mother's bile becomes rapidly richer in cholesterin. Landau¹² has confirmed Picard in establishing the adrenals as the organs for the storage of cholesterin, which makes them a necessary intermediate agency in its metabolism. The human liver contains only insignificant quantities of cholesterin, and hence cannot be regarded as a depot for its storage. The spleen, lymph glands, and bone marrow also participate in the reception and metabolism of cholesterin.

METABOLISM OF IRON.

After a large amount of experimental work, Bayer¹³ has reached the conclusion that the spleen retains and holds the iron which becomes free from the breaking down of the cells of the body and prevents hemolysis. Furthermore, it utilizes this iron in the building of new cells, especially of hemoglobin. This organ also produces a hormone that paralyzes the autonomous system; when this hormone is eliminated, its influence is shown negatively by an increase in intestinal peristalsis. The spleen and thymus have a mutual compensatory action. That the quantitative estimation of the urine iron provides no measure of the destruction of blood in pernicious anemia, has been shown by Queckenstedt¹⁴, since its elimination by the kidneys is entirely independent of the iron metabolism in the body; the fecal iron also shows no relation to the rapidity or extent of the destruction of blood corpuscles. After removal of the thymus glands, the splenic function is much increased, and vice versa; the increased function of the thymus demonstrates itself in symptoms of an exaggerated vagotonus. The increased destruction of iron-containing cells after splenectomy is shown by a lessened erythrocyte count and hemoglobin, in a lymphocytosis and eosinophilia. In Banti's disease there is a severe check to the activity of the spleen, much as in myelolytic leukemia. In both cases, however, there is marked alteration in one function, not in all the activities of the spleen. In Banti's disease, after operation, the conditions are exactly the same as in a splenectomized normal individual.

URIC ACID.

Graham and Poulton¹⁵ have found that not only does the endogenous uric acid diminish when the protein food is removed from the diet, as was shown by Folin, but also that a similar diminution occurs when the carbohydrate food is withdrawn. From these facts they attempt to construct an hypothesis of the formation of this acid by synthesis of protein and carbohydrates.

Much discussion has been aroused as to the state of the sodium urate in super-saturated solutions. Kohler¹⁶ adds to this by experimental evidence that, by means of dialysis and electrical conductivity, he has proved sodium urate is not in a colloidal state in such concentrations, but in a true solution though a super-saturated one. In urine also there is a similar solution from which the natural weakly acid reaction sets no uric acid free, while, here, there is no equilibrium between urates and uric acid, since the conditions for solution are much more favorable.

From the investigations which Bass¹⁷ has conducted, he is assured that atophan does reduce the amount of uric acid in the blood. He attributes this to the action of atophan in stimulating the uric acid excreting power of the kidney. The question is then open as to whether this increased elimination comes from a more active formation or from a stored up supply. Hopes are offered that, by a more accurate estimation of this substance in the blood this matter may be decided.

By transfusion of the livers of dogs, Rosenberg¹⁸ has learned that it is possible to extract purin bodies, even when the dog has been kept on a purin-free diet; in fact there are two ways in which to vary the amount which can be extracted: first, before the transfusion by variation of the exogenous purins, the amount may be increased when the dog has been fed on nuclein-containing food and diminished on nuclein-free food; secondly, during the transfusion, when the quantity may be increased by the addition of atophan or adrenalin to the transfusing fluid. The increase under the influence of these drugs may sometimes be more than a half of the total daily purin output of the animal. His conclusion is that atophan mobilizes uric acid.

Working with the colorimetric method of Folin¹⁹, Steinitz has been enabled by his (Steinitz's) modification to estimate accurately and easily the uric acid in 10 c.c. of blood. His results show that the endogenous uric acid amounts normally to 0.02-0.04 parts per thousand, while that of the gouty individual increases to 0.04-0.075 per thousand. Great emphasis is laid on the diagnostic value of this increase, though one should not rely upon this factor alone for a diagnosis of gout.

TESTS FOR EARLY DIAGNOSIS OF GASTRIC CANCER.

The glycyl-tryptophan test has been subjected by Hauschild²⁰ to a rigid revision, who found that of 26 cases of benign achylia, 11 gave posi-

tive reactions (splitting of the amino-acid and detection of free tryptophan). His explanation is that gastric juice contains trypsin much oftener than supposed, but the enzyme is destroyed when any considerable amount of free hydrochloric acid is present. In one case reported of proven cancer, with a free hydrochloric acid of 16, the test was negative. Further, 28 cases of certain gastric cancer, proven either by a mass or by laparotomy, were tested and 19 gave positive reactions, while 9 were negative. Hence he comes to the conclusion that the test is associated, practically, with so many errors that it cannot be relied upon for an early diagnosis of cancer.

The quantitative determination of the dissolved albumen in gastric content extract, according to Wolff-Junghans, has been studied by Smithies²¹, who found that only 80% of true gastric cancer gave this test, while in benign achylia none responded to the test.

The detection of dialyzable digestive products, which we also hoped to be diagnostic of cancer, has been found by Wasserthal²² to be common in achylia. In gastric ulcers with hyperchlohydria the test has also been found positive, but very faint.

Book Reviews.

Urgent Surgery. By FÉLIX LEJARS, Professeur Agrégé à la Faculté de Médecine de Paris; Chirurgien de l'Hôpital Saint-Antoine; Membre de la Société de Chirurgie. Translated from the seventh French edition by WILLIAM S. DICKIE, F.R.C.S.; Surgeon North Riding Infirmary, Middlesbrough; Consulting Surgeon, Easton Hospital. Third English impression. With 20 full-page plates and 1086 illustrations, of which 739 are drawn by Dr. E. Daleine and A. Leuba, and 198 are from original photographs. Vol. I: Introductory, Head, Neck, Chest, Spine, Abdomen. New York: William Wood and Company. 1914.

This is the first volume of the third English impression from the most recent seventh French edition. The author says: "The book has again been minutely revised and extensively remodelled. It has not been enlarged, though this edition contains five new chapters on acute dilatation of the stomach, acute pancreatitis, obstruction of the mesenteric vessels, sigmoiditis and perisigmoiditis, and dislocation of the pelvis, many technical changes and new methods, and 92 additional figures; but on the other hand, many of the old figures have been reduced in size, most of the photographs eliminated, and the text in places abridged."

This new edition of a well-known book is admirable. Previous favorable criticisms must be repeated. The book is essentially French. It is, after all, practically a manual of operative surgery, since all surgical procedures are, nowadays, at least, potentially urgent. Most of its references are to French and continental authorities. No mention is made of the exceptionally efficient American bone instruments. There are, it is true, a few references to articles written by American surgeons, but they form a very small proportion. This is, of course, not necessarily a disadvantage, for the American reader is naturally familiar with American literature, and glad to get a large number of references to continental authorities.

The printing of the book is equal to the best that we have come to expect from the American Press, and the volume is lavishly illustrated by accurate and artistic pictures, essentially French in detail and finish.

THE BOSTON

Medical and Surgical Journal

An independently owned Journal of Medicine and Surgery, published weekly, under the direction of the Editors and an Advisory Committee, by the BOSTON MEDICAL AND SURGICAL JOURNAL SOCIETY, INC.

THURSDAY, MARCH 11, 1915.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States. \$6.56 per year for all foreign countries belonging to the Postal Union.

The editor will be in the editorial office daily, except Wednesday and Sunday, from twelve to one-thirty p. m.

Papers for publication and all other communications for the Editorial Department should be addressed to the Editor, 126 Massachusetts Ave., Boston. Notices and other material for the editorial pages must be received not later than noon on the Saturday preceding the date of publication. Orders for reprints must be returned in writing to the printer with the galley proof of papers. The Journal will furnish the first one hundred reprints for half the cost price.

All letters containing business communications, or referring to the publication, subscription, or advertising department of the Journal, should be addressed to

ERNEST GREGORY, *Manager.*

126 Massachusetts Ave., Corner Boylston St., Boston, Massachusetts.

THE QUESTION OF EARLY MARRIAGE.

IN the issue of the JOURNAL for January 28, we published an editorial on "The Biologic Aspects of Early Marriage," in which we referred to the offer of a reward of \$200 by Caspar L. Redfield of Chicago, for the reporting of human cases "where rapid breeding led to good results from an intellectual point of view." The time limit of this offer expired without the production of evidence of the kind required, but at the annual meeting of the Council of the American Genetic Association it was voted that, the question being still open, Mr. Redfield be invited to extend his offer for another year. This extension was granted and the offer is now open until December 31, 1915.

In our previous editorial we commented at length on Mr. Redfield's position as evidenced in his paper on "The Results of Early Marriage" in the *Journal of Heredity* in July, 1914. This position is further discussed in another contribution on "The Early Marriage Question" in

a later issue of the same publication. In support of the contention in favor of the twenty-five year generation, as made in the JOURNAL, is cited an article by R. H. Johnson in the *Journal of Heredity* for March, 1914.

"Suppose a generation to be 25 years or 33 1-3 years respectively in two different stocks, and that all persons marry and each couple have four surviving children, or two for each parent. The result is that the 25-year stock constitutes two-thirds of the population at the end of a century."

"By a combination of these two causes (to which might be added the lower death-rate claimed among the children of young parents), the result is, as Galton says, that 'if the races best fitted to occupy the land are encouraged to marry early, they will breed down the others in a very few generations.'

"Something similar has happened in New England and many other regions, where a fertile foreign stock, marrying early, has nearly supplanted the earlier stock. The fact has frequently been a text for eugenic sermons."

It was in reply to this paper that Mr. Redfield's offer was originally made, he holding the converse position. Among the pedigrees submitted in competition for this offer were several by J. B. Nicklin, Jr., of Chattanooga, Tenn., including those of the present royal families of England and Germany, the Austrian, Swedish and Danish royal families, the Washington, Lee, Taylor and Hamilton families of America. Mr. Nicklin believed that these proved the production of four, five and six desirable generations in a century. Mr. Redfield, however, did not regard these data as fulfilling the terms of the offer, his objections being as follows:—

"First, the persons named are not among 'the 2000 or 3000 intellectually eminent men known to history,' whose names are recorded in ordinary encyclopedias because of intellectual achievements. Not all royal personages noted in encyclopedias are there because of their intellectual superiority.

"Second, the pedigrees given are neither complete pedigrees, nor in the tail-male lines for partial pedigrees.

"The generations of the offer are periods of time between parent and offspring. Except in the last case, you give four such periods, and consequently four generations, instead of five, as you represent it.

"Examples of breeding much more rapid than those you give are quite common, as among the 'Jukes' and other degenerate families of the United States; also in Asia, Africa and Polynesia. Marriages between boys less than 17 and girls less than 15 are the ordinary thing in many places. But the trouble with that kind of

breeding is that it does not produce superior individuals. When we come to the greatest men, they are not produced when the breeding is as rapid as three generations to the century. My money offer was for the purpose of finding any possible exception, if it existed."

Other similar pedigrees were submitted by Mrs. Elizabeth Sourdry of St. Louis, Mo. The following were Mr. Redfield's objections and comments on her material:—

"The first objection is that these men are mental mediocrities and not intellectual giants. William II is prominent because he inherited the position of emperor, but he has to his credit no intellectual achievements. If you are going into royalty I think that you should take such men as Augustus, Peter the Great or Gustavus Adolphus.

"Consider Moses, who not only controlled an unruly mob but who formulated moral laws and regulations which are good after nearly 3500 years.

"Consider Confucius, whose intellect produced the moral precepts which have guided hundreds of millions for more than 2500 years.

"Consider Aristotle, who was the main scientific authority for the world for more than 1000 years.

"Imagine a sickly little fellow sitting in Washington and changing this republic into a monarchy by the sheer force of his intellect. Imagine his influence with Congress being so great that the country would officially confer on him a title certifying the profound respect all entertained for his surpassing wisdom. That would be Augustus of Rome."

After careful consideration of the letters submitting these two groups of data, the council of the American Genetic Association decided that the requirements of the offer had not been fulfilled. Subsequent to this decision Professor Johnson further submitted a letter reiterating his position, in part as follows:—

"Mr. Redfield is quite safe in holding that in illustrious stocks the generations are long. It is just this that I contend calls for remedy. To conclude from this, however, that late children are superior mentally is wholly unwarranted. Such late births will still be found to be prevalent with the superior, irrespective of whether late children shall be shown to be equal or superior to early children from the same parents. The reasons for these delayed marriages and births are now too familiar to call for repetition here.

"May I in turn suggest to Mr. Redfield a sound method of testing his hypothesis? Ascertain the number of brothers and the ordinal position among these of all the men in some standard collection of the names of illustrious men which will furnish the desired information. Sisters, owing

to the different chance of becoming renowned, and half-brothers and step-brothers are not to be admitted. Compare the age of the parents at the birth of the most illustrious with the average age of his brothers in each family. Aside from this, even if Mr. Redfield's hypothesis prove correct, is it still true that inferior stocks are producing more early children as well as children in general than are the superior stocks. The mere lengthening of the generations of all stocks will not change the ill-balanced production of the next generation. It is necessary to increase the reproduction of the superior relative to the inferior, no matter to what other device resort may be had. Later marriage of the superior as compared with the inferior is, therefore, necessarily dysgenic."

As a matter of fact it seems that probably Professor Johnson's position is more fundamentally sound than that of Mr. Redfield's, though his contentions cannot be considered as yet proved. What is really desirable is not the production of the largest number of individuals of intellectual or other eminence, but of a community with a minimum of defectives and a maximum of physically and intellectually wholesome individuals of the most durable and most highly potential stock. The precise method by which this may be attained is yet to be determined, if indeed it be determinable otherwise than by slow and natural evolutionary processes.

A NEW ERA IN CHINESE MEDICAL EDUCATION.

So intently has the spirit of scientific medicine in America centered its attention on Europe in matters of professional regard, that affairs of epochal importance may occur in other parts of the world without the merest recognition. In spite of the rapidly developing relations between China and America, the medical profession of America has kept itself comparatively uninformed of medical progress and conditions, as well as of medical opportunities in China. It is *a priori* true that the medical future of China and her advance in paths of sanitary and public health reform, are bound up in the development of a native Chinese school of medicine, which, having been trained by the West, shall be able and eager to apply that training, under most favoring circumstances of popular support, and

knowledge of local conditions, to the upbuilding of Chinese social and sanitary life. Western medical education in China has been thus far a protégé of the missionary movement, and while the Chinese government and local institutions have made various more or less successful attempts, various defects have to a great extent nullified both types for effective service.

There has, however, within the past year been put in operation a plan for medical education which avoids the defects of both the older systems and which has many advantages they could never claim. At the biennial convention of the China Medical Association held at Shanghai, Feb. 1 to 5, 1915, Dr. F. C. Yen (Yen, F. C. An Example of Coöperation with the Chinese in Medical Education) described the plan and inauguration of the Hunan-Yale Medical School at Changsha in Hunan Province in Central China. Dr. Yen is a senior member of the medical staff of Yale-in-China. Because of his Western professional training and his influential relations in China, he combines in a singular degree the advantages of modern scientific ideals and of leadership with the Chinese. The Hunan-Yale Medical School exists under a coöperative contract between Yale-in-China and the Hunan provincial government. The peculiar advantage of such coöperation lies in the fact that it enlists the good will of the Chinese, removes suspicion by making them partners, secures indispensable practical aid, and gives the institution permanency.

Dr. Yen describes the seven years of preparation for this agreement on the part of Yale by an unvarying policy of cultivating the friendship and confidence of the Chinese. The result was that the announcement in 1913 of a large gift in America for a new Yale Hospital was followed at once by a petition from the Chinese that Yale-in-China should coöperate with the provincial government in a scheme for medical education in Changsha. "On their own initiative, over eighty of the prominent gentry of Hunan, led by provincial officials, sent a joint petition to the governor, requesting him in the name of the Hunan government to enter into a working agreement with Yale for the immediate establishment of a medical school. This request was granted and the agreement was signed in July, 1913, between Yale on the one side and the governor representing the Hunan government on the other. Thus was born the Hunan-Yale Medical School."

Under this agreement, provision was made in addition to a medical school, for two nursing schools for men and women respectively, a teaching hospital, and a research institute for the investigation of public health problems and diseases peculiar to China. The government undertakes to provide school buildings to cost \$156,000, Mex., nine acres of land valued at \$50,000, Mex., and an annual sum for maintenance of \$50,000, Mex. Yale's share is to supply a hospital costing \$150,000, gold, and a staff of fifteen doctors. To avoid establishing a precedent which might be turned to ulterior ends by other persons wishing to make direct contracts with provincial governments, the Peking government required that the Hunan-Yale agreement should be drawn between Yale and an incorporated association of Chinese, including the provincials and representing the provincial government. The obligations of this association are borne by the government.

The institution is controlled by a board of twenty trustees, half Chinese and half from Yale. An executive committee of seven transacts current business. The contract is to last ten years on trial, and if found satisfactory, is then to be subject to indefinite extension. The Chinese members of the board of trustees have voluntarily placed entire authority in technical matters with the Yale medical staff. They have also insisted that English must be the teaching language of the school.

The Hunan-Yale coöperative agreement for medical education has undergone severe testing and is the stronger for it. It has twice been submitted to the cabinet of Yuan Shih-kai and twice approved. It has been approved and supported by three successive governors of Hunan province. It has received formal sanction and approval from the Boards of Education, Finance, and Foreign Affairs of the Chinese national government. It has been supported by two parties of opposite political views in Hunan. The government has paid \$20,000 of the first installment and has given outright buildings valued at \$50,000, Mex., for the use of the school and hospital, pending the erection of permanent buildings. A medical preparatory course and the two nurses' training schools are now in operation, and the Yale Hospital is under the control of the joint board.

It is significant that the Hunan-Yale medical agreement has been inaugurated at the initiative of the Chinese in a province which is perhaps the

most independent and haughty of all China, and that it is being supported with enthusiasm and loyalty by the Chinese. It is entirely without precedent in China and marks the inauguration of a new era in the medical development of China. Dr. Yen closes his paper with the significant words: "The time has come when coöperation with the Chinese is no longer an idle dream, but may be materialized in fact. The Chinese are getting to know the foreigners better and are prepared to unite with them in such movements as this. But the initiative must come from the foreigners. Where coöperation is sought it is given, but the degree of success must necessarily depend on the spirit in which it is entered. In proportion to the fairness, loyalty and enthusiasm of the foreign party, will be the cordiality, interest and support of the Chinese."

THE MEDICAL EXAMINATION OF TRANSPORTATION OPERATORS.

THE really great progress made in the perfection of mechanical contrivances in recent times, has given a false sense of security in trusting the safety of operation to the automatic in mechanisms, and in neglecting the human physical element almost entirely. This is the ideal in mechanics but it disregards the fact that human physical development and human acuity and refinement must keep pace with the mechanical refinements, and that the latter is the outgrowth of the former. The highest degree of safety in the operation of mechanical devices is attained only with a high degree of human efficiency and refinement. The more accurate and the finer the instruments, the more delicate must be the human forces which control them. The greater the force put into harness by mechanical genius, the greater element of destruction it may become unless under the control of the most perfect physically and the most well-balanced mentally that advanced regulation can enforce.

This indication has been long recognized and in a measure been met in navigation, especially in the matter of visual acuity and color perception of those actually engaged in the navigation. The perception of red and green is of the utmost importance because these colors are used to in-

dicate danger, safety and direction. Blindness to these colors makes navigation almost impossible. The control of the navigable waters by the central government allows uniformity of examination of navigators to see that the visual and color requirements are carried out. The color and visual requirements are rather gross and should not embrace the only attempts at the selection of human fitness comparable with the mechanical magnitude.

The alarming increase in land transportation disasters calls attention to the fact that railroad and other vehicles do not have even the little regulation that navigation has, even though transportation on land is as great as, if not a greater medium than, on water. To require a pilot to conform to the color and visual requirements when his field of operation is wide, his speed comparatively slow, and with assistants usually many, should require engine and other transportation operators, who control mechanisms of high speed and higher destructive power, to conform likewise to a uniform standard of fitness, maintained by constant supervision. This should apply to automobile operators who run between the States. All forms of transportation which engage in interstate traffic of any kind are under the control of the central government, which has sole and plenary powers in such matters. All persons, therefore, engaged in the operation of vehicles in interstate traffic should be required to undergo periodic examination by medical officers of the Public Health Service, who already conduct the examination of navigators. And the enlargement of the physical requirements, to embrace not only the visual and color elements, but all physical and mental elements, would guarantee the highest efficiency and the greatest safety.

Evidence of alcoholic indulgence should be a bar to license. The heat and the stress of a "run" of locomotive operators react badly on those addicted to alcohol, either steadily or dipsomatically. Many examples of poor judgment, ignoring of signals, physical inability and exhaustion would be eliminated. In this respect the Navy has set an excellent example. Alcoholic sclerosis and the allied mental phenomena and the consequent instability are not compatible with work of this nature.

A mental examination would in many cases detect incipient paresis and other forms of psy-

oses which must be large elements in inefficiency of operators.

Legislation for the uniform control of the operators of vehicles engaged in interstate traffic a logical measure of progress—no issuance of license or renewals except after successfully passing a rigid medical examination. This should include the physical, taking into consideration the kind of vehicular operation engaged in, and emphasizing cardiovascular scleroses; a mental examination for all forms of mental aberration, but especially general paresis, alcoholic and drug intoxications and psychoses. The time may come, let it be hoped in the near future, when persons will be barred from these occupations because temperamentally unfitted.

THE IMPORTANCE OF PREGNANCY CARE.

THE lowering of the rate of infant mortality everywhere that special attention has been given to it, although in itself very encouraging, should not blind us to the immense amount of loss of life which is never recorded at all, as from abortion and miscarriage; or but scantily noticed, as in the high percentage of stillbirths which pass unconsidered in reckoning the death-rate. In every hundred pregnancies probably at least 10% fail of fruition, and between 30 and 40 children out of every 1000 are born dead. Without counting these stillbirths the deaths of children during the first month of life amount to between 35% and 40% of the total deaths occurring in the first year, and the greater part of these early deaths are due to prenatal causes or to accidents of childbirth, most of which are preventable.

The value of pregnancy care is shown very graphically by the statistics for five years of such work, given in the last report of the Committee on Prenatal Care of the Women's Municipal League of Boston, for, as this committee have no obstetrical care to patients until after the date of this report, pregnancy care may fairly be considered as being largely responsible for the results. One nurse alone was employed, and the work has always been carried on as an experiment,—to test methods rather than to accomplish results on a large scale.

Cases carried safely to labour.....	1512
Death during labour.....	0
Deaths during childbirth.....	9
Percentage	6%
Miscarriages	3
Percentage	19%
(No miscarriage has occurred during the past 3½ years.)	
Babies born	1522
Average birthweight including premature babies	7 lbs. 11 oz.
Premature babies including twins and still births, percentage	1.7%
Stillbirths including premature births for two years	1.8%
(Less than half that of the rest of the City of Boston.)	
Deaths of babies born alive but dying in first month	43
Percentage	2.8%
Deaths of babies born alive but dying in first month throughout Boston, percentage	4.3%
Cases of eclampsia.....	4
Percentage	2%
Cases of impending eclampsia—diagnosed as such by hospitals and physicians.....1st year	60
Steadily decreasing until these number in the 5th year	2

Although no care has been taken of patients by the committee after the onset of labor, one visit has been paid at the end of a month after the birth of the infant to ascertain the method of feeding and the condition of the child. The results follow:—

Breast-fed, wholly, percentage.....	84.7%
Breast-fed, partly, percentage.....	4.5%
Total	89.2%
Bottle-fed	10.8%
Well at the end of month, breast fed wholly...	97.5%
Well at the end of month, breast-fed partly...	92.3%
Well at the end of month, bottle-fed.....	72.4%

These figures speak for themselves and further comment is unnecessary.

ANNOUNCEMENT.

WE desire to call the attention of our readers to certain alterations and, we believe, improvements in the current literature department of the JOURNAL. Beginning with this issue, the custom is abandoned of reprinting the table of contents of each periodical reviewed, in the belief that this repetition is really not of sufficient value in proportion to the space it requires. Instead, the entire space available for current literature is, and will

be, devoted to the publication of more elaborate and carefully prepared abstracts of selected articles, each under the title of the article, with reference to its place of publication. Further, these abstracts are grouped under appropriate departmental headings, so that these columns will present, each week, a comprehensive topical survey of the field of recent medical literature. The method thus adopted is essentially that which has proved successful in the English and other foreign medical publications.

After careful consideration, it has been determined to place the current literature columns in the advertising pages of the JOURNAL. It has been called to our attention by various readers that, to them, the value of the current literature abstracts lies chiefly in clipping these abstracts from the JOURNAL to file in a permanent index or card catalogue form. With the current literature in its former position in the body of the text, this could not be done without mutilating the JOURNAL and making it unfit for subsequent binding and permanent preservation. By placing the current literature in its new position, this clipping is made possible without such mutilation of the permanent portion of the JOURNAL. It will be observed also that the columns are so arranged that no two abstracts come back to back, so that all may be clipped without injury to any.

We believe that the value of current literature abstracts is greater for such use at the time of publication than for binding with the JOURNAL after the original material which they represent has passed into medical literature and is fully recorded in bibliographies and indices. Moreover, to place the current literature department in this way is an aid in maintaining and raising the high ethical standard of advertising which the JOURNAL has undertaken to observe. We believe that such a mode of arranging and displaying the current literature abstracts will make them in every way more attractive, serviceable and valuable to our readers.

MEDICAL NOTES.

RED CROSS TUBERCULOSIS FUND.—Report from Washington, D. C., on Feb. 26 announces that the sale of Red Cross seals in 1914 amounted to a total of \$2,320,000, which will be devoted to anti-tuberculosis work in the United States. Over seven million more seals were sold than in 1913.

AMERICAN MEDICAL ASSOCIATION.—The 66th annual convention of the American Medical Association will be held at San Francisco from June 21 to 25, inclusive. The railroad agencies have organized and announced a series of various trips that may be made from Eastern cities, taking in not only the convention, but a number of interesting points along the routes in both directions. Various combinations will be made to suit the time, convenience and interests of different individuals. It is hoped and expected that this opportunity, combined with the attraction of the Panama-Pacific Exposition, will make the attendance at this meeting the largest in the history of the association.

EUROPEAN WAR NOTES.—It is announced that thirty hospital ambulances, with a complement of surgeons and nurses, are shortly to be sent from France to Russia to assist the Russian army medical corps in its care of the wounded.

It is reported that the American British War Relief Association has recently sent \$800 worth of ether and chloroform and 12 cases of medical supplies for distribution and use in the military hospitals at Rouen and Havre, France.

On March 5 the total of the New York Belgian Relief Fund amounted to \$952,877.15; the New York Red Cross fund to \$464,796.11; and the Committee of Mercy fund to \$122,125.72.

On March 5 the New England Belgian Relief fund amounted to \$225,539.86; the Polish Relief fund to \$24,711.22; and the Lafayette fund to \$10,023.00.

Report from London on March 2 states that since the beginning of the war only 569 deaths have been caused by disease among the British troops. Of these, only 51 have occurred among troops at the front. The remaining 518 have been among recruits in training in England, of whom 351 have died of pneumonia. The following table presents the statistics of the incidence and mortality of the important diseases among British troops at home and at the front since the outbreak of the war.

	Expeditionary *Force.		Troops in †U. K.	
	Cases.	Deaths.	Cases.	Deaths.
Typhus fever....	0	0	0	0
Typhoid fever....	‡625	‡49	262	47

Diphtheria			783	6
Measles	\$175	\$2	1045	65
Dysentery			215	1
Pneumonia			1508	351
Cerebrospinal meningitis			62	26

* Up to Feb. 11. † Up to Jan. 31. § Including Indian troops—cases, 5; deaths, 0. || Returns not at present available.

ITEMS OF MEDICAL LEGISLATION.—On Feb. 24 the National House of Representatives passed a bill authorizing the establishment, under the United States Public Health Service, of a fed-

cal home for lepers. This bill has now been sent to the Senate.

On Feb. 24, the New Jersey Senate passed a bill advocated by the Rockefeller Institute for Medical Research designed to legalize animal experimentation in that state. This bill has now been sent to the House of Representatives.

On Feb. 27, the committee on public health of the Massachusetts General Court reported favorably a bill permitting the issuance of a search warrant for any kind of habit-forming drugs. The bill is aimed to supplement the action of the Harrison bill in suppressing the illegal use of such drugs.

On Feb. 23 a hearing was held before the committee on public health on the so-called interstate reciprocity bill, whereby it is provided that physicians registered in one state may practice in another without reexamination and registration. This bill was opposed by Dr. Walter P. Bowers and Dr. Arthur K. Stone, the respective secretaries of the State Board of Medicine and the legislative committee of the Massachusetts Medical Society. Dr. Bowers said in part:—"This bill is reasonable on the face, but in a number of states in which it has been tried it has been found that a man, incompetent in one state, has gone elsewhere on the reciprocity basis. This is an imposition on the state to which he goes, for he may take an easy examination in one state and go to another where the standard is higher, and thus compete with men much better trained. A well-equipped doctor does not object to taking another examination, for his previous record has great weight in passing him."

On March 2, a hearing was held at the State House before the legislative committee on public health, relative to a bill (Senate No. 228) proposed by the Massachusetts Dental Society, creating a new board of dental examiners, establishing a higher standard of dental education, and providing for the registration of so-called dental nurses. The bill was advocated by various dentists and opposed by others, among the latter being Dr. Thomas J. Barrett of the Massachusetts State Board of Registration in Dentistry. Much criticism of the bill was made that it was virtually agreed to draft a new measure, which was presented at another meeting of the committee on Monday of this week, March 8.

HARVEY LECTURE.—The tenth and last lecture of the current course before the Harvey Society will be delivered at the New York Academy of Medicine on Saturday evening, March 13, by Dr. Elliott P. Joslin of Harvard University on "Carbohydrate Utilization in Diabetes Based on Studies of the Respiration, Urine and Blood."

BOSTON AND NEW ENGLAND.

HARVARD CANCER COMMISSION.—The recently published second annual report of the Collis P. Huntington Memorial Hospital records the activities of this institution and of the laboratories

of the Harvard Cancer Commission for the year ended June 30, 1914. During this period a total of 150 out-patients and 48 ward cases with carcinoma were treated, and including cases of sarcoma, benign growths and other conditions, a total of 130 house patients and 230 out-patients were treated. The reports of Dr. Tyzzer, Dr. Ordway and Dr. Duane record the scientific activities in cancer and radium research. Dr. Duane's apparatus for the collection and purification of radium emanation is illustrated with two full-page plates. The report concludes with a list of the thirty-nine publications issued to date by the Harvard Cancer Commission.

APPOINTMENT OF DISTRICT HEALTH OFFICERS.—On March 1, with the approval of the Massachusetts Public Health Council, Dr. Allan J. McLaughlin, state commissioner of health, announced the appointment of the eight district health officers who are to have charge of the administration of public health affairs under the direction of the state department of health. These appointees are as follows:—

Dr. Lyman A. Jones of North Adams, Dr. William H. Coon of Haverhill, Dr. Merrill E. Champion of Arlington, Dr. Adam S. MacKnight of Fall River, Dr. William W. Walecott of Natick, Dr. Charles E. Simpson of Lowell, Dr. John S. Hitchcock of Northampton and Dr. Frank L. Morse of Somerville.

These physicians, who will be required to give their entire time to the work, will be assigned to the eight new districts established by the bill under which the present state department of health was organized. They will begin their duties on March 15. These appointments complete the working organization of the department.

HOSPITAL BEQUESTS.—The will of the late Dr. Henry Cecil Haven, filed for probate in Boston on March 2, contains a bequest of \$5000 to the Children's Hospital of Boston. Upon the death of a beneficiary the testator's real estate at Nahant, Mass., will revert to the Children's Island Sanatorium of Marblehead, Mass.

EPIZOOTIC OF FOOT AND MOUTH DISEASE.—On February 28 it was announced that two new cases of foot and mouth disease had been discovered at Waltham, Mass. Quarantine has been established in fifty-one communities, in thirty-two of which the disease was discovered in the first epizootic and in fifteen of which it is now present. During this second outbreak 640 animals have already been slaughtered.

The Animal Industry Department has sent out letters to the farmers of the Commonwealth, requesting them to maintain a strict quarantine on their own premises. It is the opinion of the department that the disease has been spread more by human beings than by the transportation of infected cattle."

On Feb. 28 also three new cases of foot and mouth disease were discovered in Oneida County, near Utica, N. Y. On March 1, 62 cattle of an infected herd were slaughtered at Woonsocket, R. I. On March 2, another case of the disease was discovered at Everett, Mass., and a new case at Fall River, Mass., making the sixteenth community in Massachusetts involved in this recrudescence epizootic.

On March 2, the ways and means committee of the Massachusetts House of Representatives reported favorably, with two amendments, the resolve (House No. 1729) accompanying Gov. Walsh's recent special message for compensation for cattle killed and property destroyed in controlling the foot and mouth disease in this state. The text of the resolve and amendments is as follows:—

“Resolved. That there be allowed and paid out of the treasury of the Commonwealth, from the ordinary revenue, a sum not exceeding one hundred and fifty thousand dollars, to be expended under the direction of the Commissioner of Animal Industry, for the payment of claims for cattle killed and property destroyed during the present epidemic of the foot and mouth disease; provided, that in cases where an appraisal has already been made by the State Department of Animal Industry or by the Federal Department of Agriculture, and assented to by the owner, the payment shall be limited to 50% of the appraised value; and that in all other cases the payment shall be limited to 50% of the health value of the cattle, to be determined by the Commissioner of Animal Industry, subject, both as regards cattle and other property, to the rights of arbitration and petition in the same manner as provided by section twenty-six of chapter ninety of the Revised Laws, relative to the destruction of animals afflicted with tuberculosis, so far as applicable. In no case shall the percentage of value to be paid by the provisions of this act, added to the amount allowed by the Government of the United States, exceed the value as hereinbefore determined.

“One amendment to the original resolve strikes out the provision that ‘in cases where the owner gave a purported bill of sale to the Commonwealth the owner shall be entitled to interest from the date of such bill of sale to the time of payment.’ It is stated that it has not been customary for the Commonwealth to pay interest.

“The other amendment changes ‘per cent.’ to ‘percentage.’ A ‘percentage’ is said to mean a sliding scale.”

CASES OF INFECTIOUS DISEASES reported to the Boston Board of Health for the week ending Mar 2, 1915: Diphtheria, 68, of which 14 are non-residents; scarlatina, 87, of which 14 are non-residents; typhoid fever, 9; measles, 154; tuberculosis, 46, of which 2 are non-residents. The death-rate of the reported deaths for the week was 17.42.

Obituary.

HENRY CUTLER BALDWIN, M.D.

DR. HENRY C. BALDWIN died suddenly February 25, in his fifty-sixth year. Although he had been in failing health for some years, he had so successfully concealed this fact from his friends, and even from his family, that his death was wholly unexpected.

Dr. Baldwin was born in Roxbury, Mass., October 27, 1859, of excellent Colonial ancestry. He was graduated from Harvard College with high rank in the class of '80, which numbered Theodore Roosevelt among its members. He at once entered the Harvard Medical School, where he was also distinguished as a scholar. He thereafter served as surgical house pupil at the Massachusetts General Hospital and later, for a time, was an assistant physician at the McLean Hospital. Before entering upon his service at the latter institution, he made a trip around the world, the remembrance of which was always a source of satisfaction in his later years. Again, after leaving the McLean Hospital, he went abroad and took a course at the Rotunda Hospital in Dublin and also made studies and observations in the Salpêtrière in Paris and elsewhere on the Continent. Returning to America, he taught for a period at the Harvard Medical School and soon thereafter became associated with Dr. James J. Putnam in the neurological department of the Massachusetts General Hospital. He rose through the various ranks until he became one of the neurologists to the hospital, a position which he held at the time of his death. For many years he was officially connected with the Free Hospital for Women, but finally resigned to devote all his energy to the work of the Massachusetts General Hospital clinic.

Apart from his hospital work, in which his enthusiasm never flagged, he was, at one time, a member of Mayor Quincy's advisory board of visitors to public institutions and chairman of the board of trustees of the Boston Insane Hospital. These public functions he performed in addition to his active private practice, which concerned itself largely, but by no means exclusively, with disorders of the nervous system. He was a member of the Massachusetts Medical Society, of the American Medical Association, of the American Medico-Psychological Association, of the American Neurological Association, of the Boston Society for Medical Improvement, and of the Boston Medical Library. He was especially interested in the Boston Society of Psychiatry and Neurology, of which he was, at one time, president. At a recent anniversary dinner of this society only a few weeks before his death he took charge of the music and sang with his accustomed vigor.

Apart from his professional interests, which always occupied his chief attention, he took great pleasure in music and was himself the possessor of an excellent voice. He was a member of

the Cecilia Society, which he joined in 1883, singing at the first concert of the society in that year. He was several times a director of the society and, for the past three years, had been very active in maintaining its integrity. He never belonged to the so-called "Doctors' chorus," and the Harvard Alumni chorus. Vocal music was his special delight and relaxation. A further characteristic interest was his love for animals. He always had dogs of recognized lineage and was an enthusiastic horseback rider. Although in certain respects eminently social, he cared little for what is popularly called society; his work and his home life remained throughout his chief interests.

Of all his activities, his relation to the Massachusetts General Hospital undoubtedly took first place. He was an extremely loyal friend to the institution and worked always for its best interests. He was never neglectful of what he considered his duty, and up to a few days before his death was seeing patients and prescribing treatment as he had been doing for nearly three decades. He was a strict disciplinarian and felt very strongly that the welfare of the hospital depended upon the maintenance of this discipline. While he insisted that his subordinates should obey the rules strictly, he never shirked his own responsibility or regarded himself as exempt from the regulations which he imposed on others. The hospital has lost in him a loyal and devoted friend.

He was not a voluminous writer and he did not often take part in discussions at medical meetings, but his interest in the progress of medicine remained unabated. His strength lay in his power of organization and in his capacity to accomplish work which he set himself. He was indefatigable in his treatment, especially by mechanical means, of certain stubborn nervous disorders, and accomplished at times what seemed impossible in overcoming apparently hopeless muscular incapacity. He was no less active during the final years of impaired health than he had been before, and bore his increasing health courageously, with the determination, largely successful, of keeping from his colleagues the serious disability from which he was suffering. Although undoubtedly aware of his deplorable condition, even on the day of his death, during his periods of consciousness, he was normal in mind and apparently wholly unconcerned. As a man, few knew him intimately, but those who did found in him much to respect and admire. A widow and one brother survive him.

APPOINTMENTS.

UNIVERSITY OF LONDON.—*Dr. Edward Barclay-Smith*, Cambridge, has been appointed professor of anatomy at Kings College in succession to *Dr. Watterston*; and *Dr. E. P. Cathcart* of Glasgow has been appointed to succeed *Dr. Leonard Hill* as professor of physiology at the London Hospital Medical College.

Miscellany.

WORK OF DR. CARREL IN FRANCE.

THE Rockefeller Institute for Medical Research has recently communicated the following information relative to the work of *Dr. Alexis Carrel* in France. *Dr. Carrel* has now been detached from the Lyons Hospital and placed in charge of a hospital at the Campagne near the northern line of battle.

For the use of the patients in charge of *Dr. Carrel* and his assistants, the government has requisitioned a hotel, which has been converted into a hospital with accommodations for about one hundred persons. The government will provide administrative officers as well as competent surgeons suggested by *Dr. Carrel*, to carry on the regular work, thus leaving *Dr. Carrel* free to perform his characteristic operations, especially in the line of transplanting tissues, blood vessels and nerves, and blood transfusion, and to conduct the laboratory studies which are about to be undertaken.

In order that the work under *Dr. Carrel* may not only be of the greatest effectiveness at the moment, but may be made permanently available to the world of science, the Rockefeller Institute is equipping *Dr. Carrel's* hospital with complete apparatus for research in the bacteriological, pathological, chemical and surgical conditions which may arise.

Dr. Carrel, who was spending his vacation in France at the outbreak of the War, immediately offered his services to the French government, which were accepted. He was detailed to the military hospital at Lyons, at which there were referred to him especially the wounded with injured blood vessels and nerves, in view of the research work which he had done in these classes of injuries. From the application of the method which he discovered for suturing and transplanting blood vessels and tissue, it was possible to save limbs which otherwise would have inevitably been lost. *Dr. Carrel* has now been given special facilities as near as possible to the line of battle, because of the unusual conditions which have developed in this conflict incident to trench warfare.

It has been supposed that all future wars would yield small numbers of infected wounds. The facts, however, are that no previous war has yielded such a large number of infected wounds as the present one.

The reasons for this under the old conditions are developed to be as follows: poor hygienic facilities, infection of the wounds caused by the surgeons who carried the infecting germs on the operating instruments, dressings, etc., the introduction of infected material from without at the time of injury, were the sources of infection. In the present case the infections occur because the injured in trenches receive their injuries

from missiles which carry dirt and soiled clothing into wounds; and also because in many cases it is days before the injured can be removed. The infections have also been of an unusual character. Formerly they were usually suppuration and pus formation. Now they are commonly due to the development of gas in the tissues and to tetanus or lock-jaw.

"This gas infection is very serious in form. It originates in bacteria of the soil, particularly soil which has been under a high state of cultivation for a long period of years. The technological term applied to the condition in gaseous phlegmon. The bacteria which cause it do not grow except in the absence of atmospheric air which the injured tissues provide. In their growth they break up the constituents of the tissues and impart a gas in which hydrogen forms a large part. This gas penetrates the tissues and carries the infected material further and further and may penetrate into the blood, when it soon causes rapid death.

"Hitherto this class of infection has been so rare that adequate means for its prevention and cure have hardly been worked out. It is in order that he might have access to this class of cases, now, unfortunately, so numerous, that Dr. Carrel has been transferred to the northern field of war. It is in order that, in addition to the regular routine work of the care of the wounded, he may study these infections especially, he is being provided by the Rockefeller Institute for Medical Research with the medical equipment requisite for this work.

"In carrying out the enormous work incidental to military operations one government alone could hardly undertake at this critical period to organize hospitals and laboratories for conducting research work. They must be quite content to deal with conditions as they arise. It is just there that Dr. Carrel's peculiar qualifications come in, and in that respect that the contribution of the Rockefeller Institute is largely made.

"Hence it is that he is to have a staff consisting of bacteriologists, chemists and technicians, forming a laboratory unit in addition to the regular surgical unit of the hospital. He is fortunate in being joined by Dr. H. D. Dakin, who has been for many years in this country and has a distinguished reputation as a chemist. He has been assigned to take charge of the chemical part of this humane work of investigation.

"The Rockefeller Foundation has just voted an appropriation of \$20,000, to be used under the direction of the Rockefeller Institute, in furthering medical research work under war conditions.

"The Institute has had many appeals made to it for serum for use in the treatment of meningitis and dysentery and these serums have been distributed freely."

CO-OPERATION OF THE CLERICAL AND MEDICAL PROFESSION.

As the result of a suggestion in the editorial on "The Minister and the Doctor," published in the issue of the JOURNAL for Oct. 1, 1914 (Vol. clxxi, page 532), a committee was appointed by the Massachusetts Federation of Churches to confer with a similar committee of the Massachusetts Medical Society on the subject of co-operation between the clerical and medical professions in the solution of problems of public health. At a joint meeting of these two committees in Boston on Feb. 24, 1915, the following votes were passed as representing the opinion of the meeting:—

"1. That intimate and practical coöperation should be established and maintained between the Massachusetts Federation of Churches and the Massachusetts Medical Society for the purpose of improving public health in this Commonwealth.

"2. That the churches of every community (through their local federation, where one exists) should consult and coöperate with its physicians in matters of public health.

"3. That the fundamental need is that of a competent health officer in every city, township or group of towns.

"4. That whatever specific local needs in the line of health are discovered, should be taken up, both educationally and practically, by the co-operation of the churches and the physicians."

The committee representing the Massachusetts Medical Society consisted of Dr. Milton J. Rosenau, Dr. Annie Lee Hamilton, and Dr. Abbie Noyes Little.

Correspondence.

THE LABOR CLEAN MILK BILL.

CANTON, MASS., February 25, 1915.

Mr. Editor: I have read your editorial "The Labor Clean Milk Bill" in the issue of February 25th and am somewhat surprised that you recommend this bill for passage without more discussion.

At the present time it is absolutely possible to control the milk situation throughout the Commonwealth with the present powers given to local boards of health. They need no further authority.

For the past two years we in our town have been able to control the supply of milk sold in the town. This is our method: We license every dealer and producer. We examine the milk of every dealer both for cleanliness and quality at least once a month. His record for that examination is published each month in the local paper. Any dealer whose milk is below the standard is personally notified that he must improve. If his milk continues to be below standard we prohibit his selling until such time as we are satisfied that he produces clean milk. We hold dealers responsible for milk coming from dairies outside the town. This method has proved satisfactory and efficient.

When I first heard of this bill, I wrote to Mr. Myron E. Pierce, counsel for the Massachusetts Milk Consumers' Association, stating the above opinion. This is a quotation from his letter in reply: "There

no particular need of the bill so far as the powers local boards are concerned, but there is great need, seems to me, of some such bill to give the State board of Health adequate powers, etc."

Thus the bill seems to be one to increase the powers the State Board of Health and not primarily one enable us to obtain cleaner milk. This method of taining power for the State Board of Health seems me questionable. I believe with many others that e State Board of Health should have more authority all health matters but I do not believe they should ve a little here and a little more there, given them a series of various kinds of laws until it will be ry difficult to know just how much power they do ve in any particular case.

Let the State Board of Health be given adequate wer in all health matters and over local boards of alth, if you will, through some comprehensive legis- ion, but let us keep off the Statute books such un- necessary laws as this bill (Senate No. 78) will be. It seems to me this bill should be further discussed fore it is so heartily recommended.

Respectfully yours,

DEAN S. LUCE, M.D.

SURGICAL INSTRUMENTS FOR THE EUROPEAN WAR.

BOSTON, March 3, 1915.

Mr. Editor: I beg leave to make a final report on e instrument-collecting enterprise which you have e kind enough to notice in your columns.

Through the coöperation of the profession and veral of the surgical instrument makers in the city as able to send away—mainly to Servia and Rus- , but into France also—fourteen lots of instru- ents, consisting of three large barrels, two trunks, cking cases and a number of smaller packages. Besides these, Dr. Seabury W. Allen contributed a luable Heinze X-ray apparatus in excellent order. d in addition to the gifts from the surgical instru- ment makers which have been previously acknowledged, collection of instruments of value was sent me by e E. F. Mahady Company.

I desire again to express my appreciation of this d coöperation.

Very truly yours,

JAMES J. PUTNAM, M.D.

A REJOINDER.

DORCHESTER, MASS., February 20, 1915.

Mr. Editor: Dr. Richard C. Cabot in the issue of b. 18, 1915, of the JOURNAL, attempts to explain herein his attacks upon the medical profession agree th and differ from those of Mr. George Bernard aw. Had he brought his criticism to the Medical ofession through its regularly constituted channels communication rather than by way of the lay press ould not now be necessary for him to try to "court misrepresentations." Even if the alleged short mings of physicians were of flagrant and serious a ture, was it wise or necessary for a member of the ofession voluntarily to expose them before the ever rious public? Such methods undermine the confi- ence and lower the esteem in which we, as physi- ans, wish and ought to be held by the whole world. onstructive, helpful criticisms are always well re- ived and desired by medical men when advanced in e council chambers of their medical societies and urnals. However much one may coincide with t. Cabot's ideas relative to medical abuses, and his eories of medical reform, the profession may justly ittle and resent the manner chosen by him, in vling to bring about the changes which he advocates.

Very truly yours,

SAMUEL CROWELL, M.D.

F. F. SIMPSON, M.D., Treasurer.

In addition to the financial report for the week end- ing February 27th, the Treasurer would call the at- tention of the medical profession to the following letters:

"BALTIMORE, February 23, 1915.

"My Dear Dr. Simpson: Your letter of February nineteenth received. Madam DePage was in Balti- more for a short time last week. I told her something of the work that the medical men in this country were doing for their confreres in Belgium. She was much interested and most grateful for what had al- ready been done. She is in this country commissioned by the King of Belgium, to whom her husband is per- sonal physician, to do everything she could to secure contributions for her starving countrymen. Her ac- count of conditions in Belgium is pathetically interest- ing. The needs of her country beggar description. While so much is being done and has already been done by this country, so much more must be done in order to save from starvation many hundreds of men, women and children. I wish it were possible for everyone to hear her account of what the Belgians are doing for themselves and of their gratitude for what is being done for them and, at the same time, get some sort of an appreciation of the magnitude of the need for more and immediate assistance. I feel sure it would result in a more prompt and generous re-

sponse on the part of the profession than that which has already been made.

"Madame DePage herself is now on her way across the Continent and will visit as many cities and see as many people as possible in order to deliver her message.

"With kind regards,

"Sincerely yours,

"(Signed) J. M. T. FINNEY."

The efforts of the Committee of American Physicians for the Aid of the Belgian Profession are directed toward the relief of civilian physicians and their families in the northeastern or invaded portions of Belgium.

The purpose of Madam DePage is to establish additional field hospitals and further other Red Cross work in the southwestern part of Belgium.

In a recent letter she says: "The big conflict of the present war is still in the future; the most terrific fighting of all will come this spring. We must foresee the coming slaughter and be prepared to render instant aid to the thousands of wounded, friends and foes, who will fall within our lines."

The following is an extract from a letter from Dr. J. Riddle Goffe, under date of January 26, 1915:

"The fact that the English Government has announced that it will no longer continue to grant its monthly stipend to the British Commission for Relief in Belgium comes with somewhat startling disappointment."

The work of relief must now depend almost exclusively upon contributions from the United States. This means that our efforts must be redoubled if we are eventually to reap the benefit of what has already been done and carry the Belgian people through to the time when their own meager harvest can supply their actual necessities. It must be constantly kept in mind that the status of the 1,400,000 utterly destitute in Belgium are still standing in the bread line or hovering around the soup kitchens. A recent communication from Dr. Jacobs of Brussels, gives a heartrending picture of the condition of Belgian civilian physicians and their families.

The following letter is self explanatory:

"DAYTON, OHIO, February 25, 1915.

"My dear Doctor Simpson: Pursuant to a resolution passed by The Montgomery County Medical Society, Feb. 5, 1915, authorizing a committee of three of its members, to raise a fund for the relief of the Physicians of Belgium and their families, the pleasant task was immediately started with the result indicated by the inclosed New York draft for \$304.50. We but join you and the other members of your splendid Committee in the hope that every farthing of this offering may reach our afflicted brethren in Belgium and that the end is not in the far distance when lasting, permanent relief may be their heritage.

"MONTGOMERY COUNTY MEDICAL SOCIETY,

"By its Committee:

"J. MORTON HOWELL,

"GEORGE GOODRUE,

"C. L. PATTERSON.

} Committee."

SOCIETY NOTICES.

MIDDLESEX SOUTH DISTRICT MEDICAL SOCIETY.—A special meeting of the Society will be held at the Robert B. Brigham Hospital, Parker Hill Avenue, Brookline, on Wednesday, March 17, 1915, at 12 o'clock, noon.

Clinics illustrating the work of the several departments of the hospital will be given as follows:

Dr. Louis M. Spear, "Cases of Chronic Medicine."

Dr. Edward P. Richardson, "Cases of Chronic Surgery."

Dr. Charles F. Painter, "Cases of Chronic Arthritis."

Lunch will be served at 1 P.M.

To reach the hospital:

Automobiles take Huntington Avenue to Calumet Street, Hillside Street, Parker Hill Avenue, to top of Hill.

By electric: Huntington Avenue through Brookline Village to Waite Street.

LYMAN S. HAPGOOD, M.D., *Secretary*,
6 Garden Street, Cambridge, Mass.

AMERICAN ASSOCIATION OF IMMUNOLOGISTS.—The annual meeting will be held at Washington, D. C., May 10, 1915.

MARTIN J. SYNNOTT, M.D., *Secretary*,
Montclair, N. J.

GERALD B. WEBB, M.D., *President*,
Colorado Springs, Colo.

AMERICAN POSTURE LEAGUE.—The second annual luncheon of the American Posture League will take place at the Hotel Astor, New York, on Saturday, March 13, at 1.30 P.M. The Central Committee on Public Health Organizations, which meets in New York on the same date, has been invited to attend the luncheon. Several of its members are officers or directors in the Posture League.

The after-luncheon program will set forth the educational, scientific and welfare aspects of the work of the organization. The President and founder of the League, Miss Jessie H. Bancroft, will preside and will speak on the history, plan and work of the American Posture League; other speakers will include Dr. Fredrick R. Greene, of Chicago, first vice-president of the American Posture League, and secretary of the Council on Health and Public Instruction of the American Medical Association; Dr. Joel E. Goldthwait, second vice-president, and Dr. E. G. Brackett, both of Boston. Dr. Eliza M. Mosher, Dr. Henry Ling Taylor, secretary, and Dr. S. Josephine Baker, of New York. Dr. Percy W. Roberts will present an important report of original research conducted by the League. Dr. Anna L. Brown will tell of the National contest on Posture being conducted by the Young Women's Christian Association, and Mr. Harry O. Bullock will speak for the Brooklyn Rapid Transit Company, relative to the seats in the new subway cars, which the Posture League designed in cooperation with the construction engineers of the company.

The annual meeting for the election of directors and officers will occur earlier in the day.

H. L. TAYLOR, M.D., *Secretary*.

RECENT DEATHS.

DR. JAMES F. DONNELLY, who died on February 2 at Nish, Serbia, was a graduate of the University of Louisville and a practitioner in New York City. He went to Serbia in November, 1914, with an American Red Cross unit. The cause of his death was typhus.

DR. O. K. SPRENGEL, surgeon-in-chief of the public hospital at Braunschweig, Germany, and president of the German Surgical Association died recently of septic infection at the age of 62.

DR. JAMES PECKHAM CAMPBELL, who died on Feb. 27 in New York City, was born in Lewes, England, on August 18, 1833. Migrating early to the United States he became a student at Syracuse University, at which at his death, he was the oldest living graduate. After studying medicine he was for a time a surgeon of the Cunard steamship line and later settled in the practice of his profession at Norfolk, Va., and in New York City. He is survived by three daughters and three sons.

DR. LUTHER GRAVES TOWNSEND, a retired Fellow of The Massachusetts Medical Society, died at his home in Townsend, Mass., March 1, aged 70 years. He was born in Nashua, N. H., Dec. 12, 1844, and was graduated from the Harvard Medical School in 1871, serving as house physician at the Boston Lunatic Hospital and at Deer Island after graduation. He practised at Townsend the rest of his life and was member of the school board of that town from 1888 to 1900.

PROGRESSIVE NEURO-MUSCULAR ATROPHY, (PERONEAL TYPE OF CHARCOT, MARIE AND TOOTH): WITH REPORT OF THREE CASES IN A FAMILY WITHOUT HEREDITY.*†

BY FLOYD F. HATCH, BOSTON.

[From the Medical Clinic of the Peter Bent Brigham Hospital, Boston, Mass.]

THE impulse given to the study of this type of muscular atrophy came in 1886 when Charcot and Marie¹, and Tooth² coincidently in the same year published papers reviewing the myopathies. Separately they established from clinical and pathological observations that the peroneal form, beginning usually in early childhood and involving the extremities only, depended upon neural as well as muscular degeneration and isolated it between the myopathic (muscular dystrophies) and the myelo-pathic (anterior poliomyelitis) affections.

The characteristics of the affection as originally described by Charcot and Marie are:

1. Progressive muscular atrophy beginning first in the feet and legs, not appearing in the hands and arms until several years later, the progression of the atrophy being slow.
2. Relative integrity of the muscles near the trunk, or at least much longer preservation of these than of the muscles of the distal ends of the limbs.
3. Integrity of muscles of the trunk, shoulders and face.
4. Fibrillary contractions in the atrophying

muscles. 5. Vasomotor disturbances in the portions of the limbs which have atrophied. 6. Absence of pronounced contractions of the tendons. 7. Sensations usually intact but sometimes affected. 8. Reaction of degeneration in atrophying muscles. 9. Hereditary and familial tendencies.

The three cases reported here are members of a Jewish family which came to this country in 1899. The father, a well developed and nourished man, left his wife and children several years ago. Nothing is known of his family with the exception of one brother and his family, all of whom have always been well. The mother is living and well. There is no history of paralysis or other nervous disturbance in her family. The mother does not use alcohol. The father drank at times. There are three healthy sisters, aged 21, 13 and 8 years. All children were normal deliveries, healthy infants and walked before one year of age.

CASE 1. Plates I and II. Sam F., 24 years old, has always lived at home, never having been able to work.

Complaint: "Weakness of legs and arms."

Past History: Internal strabismus of the left eye was present at birth. He had measles at two years, chicken pox at three years and whooping cough at four years of age. Entropion of both lower lids began at 17 years with falling out of the lashes and chronic irritation since that time.

Present Illness: Began at the age of seven years when weakness was noted in his feet, making walking difficult. Weakness and atrophy increased until at the age of 14 years the muscles above the knees also seemed to be involved and he fell down constantly when walking about. At 16 years the patient was wholly unable to walk and moved about by crawling. At about this time the fingers of the left hand and almost immediately of the right became weak with

* Reported at a medical meeting at the Peter Bent Brigham Hospital, November 10, 1914.

† Received for publication Dec. 22, 1914.

PLATE 1.

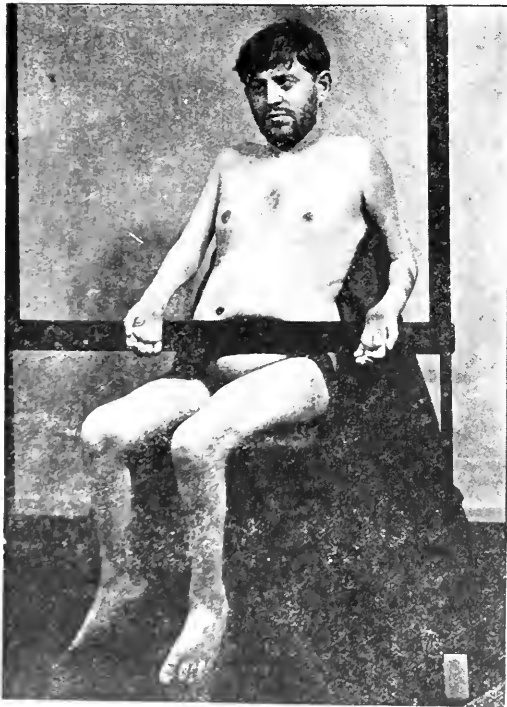

PLATE 2.

gradual development of contracture so that they could not be straightened. Subsequently the whole lower arm on both sides became involved so that at the age of 20 years he was unable to use either hand. At present there remains ability to move the third and fourth fingers of the right hand to a slight extent. No sensation of pain, cramp or discomfort has ever been felt. He sleeps well, has a good appetite and never becomes nervous or irritable. At

the present time he clumsily washes and dresses himself, using his hands in a flail-like manner but can perform no complex movements. His mentality appears normal.

Physical Examination: Shows head and body, including the shoulders and buttocks, well developed and nourished. Skin and mucous membranes are normal. Eyes show entropion of both lower lids with a low grade chronic conjunctivitis and a left internal strabismus. Pupils react equally to light. Tongue is clear and protrudes without tremor. Chest is well formed, expansion good. Lungs and heart are normal. Systolic blood pressure is 120 mm. of mercury. Abdomen is fat and somewhat protuberant, no masses or tender areas are made out. Patient sits or lies with both knees flexed at right angles to the thighs from contracture. There is evident equino-varus of both feet, most marked on the right, also a marked degree of external rotation of the whole lower right leg from atrophy and weakness of the vastus medialis. The legs are short as compared with the body, giving the patient a dwarfish appearance. Atrophy of all muscles of the legs below the middle third of the thigh is evident but to some extent obscured by the thick layer of subcutaneous fat. The hands and arms show a marked degree of atrophy and paralysis below the middle third of the upper arm, comparable with that of the feet and legs. The thenar and hypothenar eminences of both hands are absent. The hands are flattened with the terminal phalanges slightly flexed. The biceps on the right is capable of flexing the arm. The left biceps cannot accomplish this. There is practically no muscular movement below the elbows. On the left there seems to be slight weakness of the shoulder muscles. The hands and feet are about two-thirds normal size and length. The knee jerks, Achilles jerks, plantar, biceps and triceps reflexes of both sides are absent. There is no ankle clonus or Babinski sign. The cremasteric and abdominal reflexes are present.

While the patient was in the hospital fibrillary tremor at a rate of about 8 per second was noticed in his pectoral, biceps and triceps muscles, especially on the left, brought on by any attempt to move the arm. A tracing was made, by connecting the arm by electrodes with the electrocardiograph galvanometer (Plate III), and by means of an air-containing cuff around the arm connected with a recording tambour (Plate IV). These plates show graphically the electric disturbance set up by the fibrillary twitching of the muscle and the rate and degree of muscle contraction. The muscle sounds during the

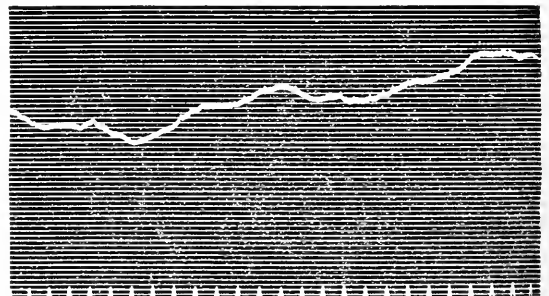

PLATE 3.

Tracings were obtained by placing the electrodes on the outer side of the left upper arm, one at the upper part and the other at the lower part of the triceps. There are fine movements of the string produced probably by muscular twitchings which result when patient tries to move his fingers.

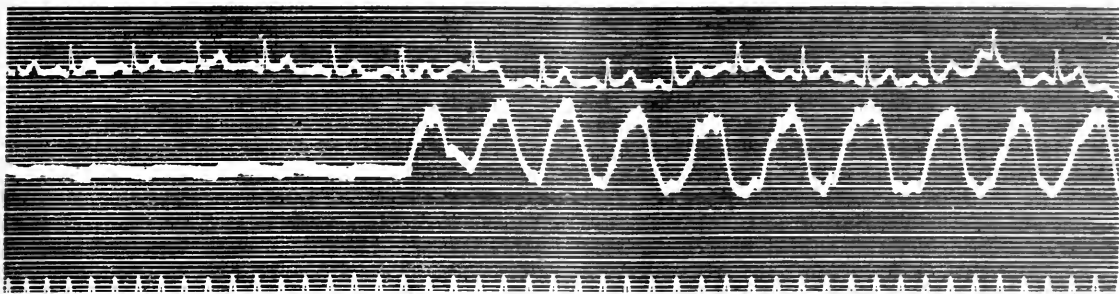

PLATE 4.

Upper curve is electrocardiogram showing normal cardiac complex. Middle curve is record obtained from a recording tambour connected with an air cuff around upper arm. First portion of the curve shows low waves produced by pulsation of brachial artery; second portion shows large and small waves produced by twitching of arm muscles. Lower curve is record of a time bar of beating one-fifth seconds.

PLATE 5.

PLATE 6.

period of tremor could readily be heard with a stethoscope. There was a similar tremor noticed in the muscles of the upper left cheek and those of the lower left lid which probably originated in the orbicularis palpebrarum. The location of these muscles was not suitable to obtain graphic tracings.

CASE 2. Plates V and VI. Harry F., 12 years old.

Complaint: "Cannot walk."

Past History: No previous illness. Digestion good. Bowels regular.

Present Illness: Began at age of seven years when he noticed that the right foot became weak and easily tired when walking. The same difficulty was encountered in the left foot about four weeks

later. The legs and feet have grown progressively weaker with marked atrophy of all muscles below the knees and six months ago he finally became unable to walk at all. About four years ago he noticed weakness followed by incoordination in his hands, appearing in the first and second fingers of the right hand. Atrophy and paralysis have progressed until at present there is no muscular control below the insertion of the biceps. His mentality appears normal.

Physical Examination: Shows a normal appearing boy of 12 years, well developed and nourished except in the musculature of the arms and legs. Pupils are equal and react to light. Tongue is protruded in the mid line without tremor. Skin and mucous membranes are normal. Chest is well

formed, expansion good. Lungs and heart are normal. Systolic blood pressure is 120 mm. of mercury. Abdomen is fat and slightly protuberant, no masses or tender areas are made out. Upper extremities show a progressive tapering from the shoulders to the hands which are held in a position of pronation, flexed at the wrists. The lower arm muscles, interossei muscles, thenar and hypothenar eminences show marked atrophy. The biceps and triceps reflexes are absent. Movements of the lower arms and hands are accomplished by flinging movements of the shoulder muscles. The lower extremities show the same type of progressive tapering. The right knee is held in position of genu valgus. Both feet show equino-varus which is especially marked on the left. The feet and hands are smaller than those of the average boy of his age and size. The atrophy of the lower legs and feet is even more obscured by the thick layer of subcutaneous fat than in the arms and hands. All muscle power below the knees is gone. The knee jerks and plantar reflexes are absent. There is no ankle clonus or Babinski sign. No muscular tremor was observed.

PLATE 7.

CASE 3. Plates VII and VIII. Mary F., 10 years old.

Complaint: "Unable to use hands or feet."

Past History: Measles at four years followed immediately by whooping cough which persisted for six months.

Present Illness: Began at age of four years about one or two months after the whooping cough, when mother noticed that the child walked peculiarly, picking up feet higher than usual and bringing them down "flail-like." The weakness in her legs gradually increased until she is now barely able to walk. The weakness was first noticed in her hands about two years ago, at which time she could perform any complicated task, but paralysis and at-

rophy gradually progressed until now she is practically helpless, being able only to feed and dress herself with difficulty. The weakness and atrophy remain localized to the lower portions of the extremities. Her mentality is normal.

Physical Examination: Patient is well developed and nourished except in the musculature of the

PLATE 8.

lower arms and legs. Pupils are equal and react to light. Teeth are in poor condition. Tongue protrudes in the mid line without tremor. Skin and mucous membranes are normal. Chest is well formed, expansion good. Lungs and heart are normal. Systolic blood pressure is 115 mm. of mercury. Abdomen is soft and rounded, no masses or tender areas are made out. The upper extremities appear normal as far down as the elbows. Flexion at the elbows seems weak but not limited. The muscles of the lower arms and hands show marked atrophy; especially noticeable is the absence of the thenar and hypothenar eminences. There is some contracture of the second, third and fourth fingers of both hands in the two distal phalangeal joints, giving the picture of an early "claw hand." Reflexes of the biceps and triceps are transient. No reflexes are present in the lower arms. The lower extremities show marked atrophy and practically complete paralysis of the muscles below the knees. The degree of atrophy is masked by thick subcutaneous fat. Both feet show equino-varus, more marked on the right. Knee jerks, Achilles jerks, and plantar reflexes are absent. No ankle or Babinski sign.

The electrocardiograms in all three cases showed the heart mechanism to be perfectly regular and normal.

The special senses, smell, sight, hearing, taste and speech as well as the general sensations of

pain, touch, position and temperature, were normal in all cases without exception. There is a well marked vaso-motor disturbance in the involved portions of the extremities in that their appearance is cyanotic and they feel cold as compared with the uninvolved portions.

Ophthalmoscopic examination showed normal fundi with the discs clearly outlined and vessels well seen throughout their course.

X-ray examination of the affected parts show evident bony atrophy, more or less failure of development of the sesamoid bones, shafts of long bones with small flaring extremities and some failure of the epiphyses to unite. In all three cases the sella turcica was small, antero-posterior diameter 10 mm., depth 6 mm.

The electrical reactions of the muscles in all three cases were very similar, varying directly with extent of the disease. The reaction of degeneration was found in muscles more recently involved (*i. e.* those about the knees and elbows). No reactions to electrical stimuli were obtained on muscles of the lower portions of the extremities in any case (*i. e.*, hands and feet). Partial reaction of degeneration was obtained in many muscle groups that appeared to be unimpaired. The muscles giving these partial reactions of degeneration were located above the atrophic muscles. This was most evident in the case of the elder boy where only very large amounts of faradic current (60-70 mil. amperes) gave muscle response in the deltoids and pectorals of the left side, while relatively small amounts of galvanic current (15-20 mil. amperes) gave similar response in normal individuals.

The clinical pathology of the urine and blood in all three cases showed normal conditions. The Wassermann reactions on the blood serum and spinal fluid in each case were negative. The spinal fluids, were, however, very interesting as shown by the following table. The coincident increase of albumin and globulin with the stage of the disease in the three cases seems a logical finding, as well as the pathological gold chloride reaction. I have not found these tests previously reported. The gold chloride reaction, as indicated by the number of the tube with the strength of reaction following, is one that simulates the cerebro-spinal syphilitic reactions, falling nearest to tabes.

The cases of this type, with atrophy confined strictly to the distal parts of the limbs, are recognized as a distinct type of neuro-muscular atrophy, with a distinct pathology. Cases of this kind with necropsy are very rare and we are obliged to depend on the findings of Marineseo³, Sainton⁴, and Dejerine and Armand-Delille⁵.

The lesions of the cases studied by Sainton were: sclerosis of the posterior columns, especially the columns of Burdach, a slight degeneration of both pyramidal tracts, alterations of the columns of Clarke, atrophy of the cells of the anterior horns, slight degeneration of the intra-muscular nerves, slight sclerosis of the nerves of

SPINAL FLUID.

Gold Chloride Reaction.

the forearms and legs very distinct in the peroneal nerves, atrophy of the muscle fibres even causing complete disappearance of some fibres with proliferation of connective tissue. In this case the atrophy began in the upper limbs. The lesions resembled those observed by Marineseo in his case, except that Marineseo found the antero-lateral columns intact.

The lesions in the case reported by Dejerine and Armand-Delille were degeneration of some of the nerve cells of the anterior horns of the cervical and lumbar regions without diminution in their number, chronic meningitis, degeneration of the muscles of the hands and feet (*i. e.*, many nerve fibres of small size, many empty nerve sheaths and a few nerve fibres in the process of degeneration). The nerve trunks, the cutaneous sensory nerves and the anterior and posterior nerve roots with slight exception were normal.

Siemerlings⁶ case is held in question as belonging to this type, as there was great atrophy of the muscles of all the extremities, the upper

limbs as well as the lower, and of the trunk. There was flaccid complete paralysis of the lower limbs so that all voluntary movements were lost. He found degeneration of the posterior and lateral columns, most intense in the lower thoracic and upper lumbar regions, degeneration of the peripheral nerves and muscles, atrophy of the cells of the anterior horns, of the columns of Clarke, of the anterior roots and of the spinal ganglia.

In the original description the type was so sharply defined that confusion with other types was supposed not to occur, but literature contains many reported cases in which some atypical features are present. Sachs⁷ reported the first two cases from this country which deviated from the original type in that the infraspinati muscles were atrophied. Oppenheim and Cassirier⁸ reported a case with involvement of the orbicularis palpebrarum. My first case is somewhat atypical in that the pectorals are weak and show the typical fibrillary contractions of early muscular atrophy and neural degeneration; otherwise the cases are absolutely typical clinical pictures of the original type descriptions and their classification cannot be questioned.

That the disease is a hereditary as well as a familial affection is well shown in the family reported by Dr. Herringham⁹. In his case, however, extending over three generations, males only were affected, though the disease was transmitted by females, following closely the hereditary features noticed in color blindness. In the family reported by Osler¹⁰ thirteen individuals were affected in two generations, seven being males and six females. Both males and females transmitted the disease. This is by far the most common. Males are affected more frequently than the females in the proportion of two to one. (Some say five to one).

Concerning the prognosis it may be said to be good so far as life is concerned; the disease is of slow development and after reaching its height the patient may live for years without having additional symptoms. Thus in a typical case reported by Spiller¹¹, symptoms are said to have been present 45 years, and the patient's condition has not changed during the many years he has been under observation. There is no reason for expecting any tendency toward improvement.

ON THE VALUE OF THE GOLD SOL TEST (LANGE) IN CEREBROSPINAL FLUID OBTAINED POST-MORTEM.*

BY H. C. SOLOMON, M.D., BOSTON.

*Assistant in Neuropathology, Harvard Medical School;
Junior Assistant Physician, Psychopathic Department,
Boston State Hospital.*

AND

E. S. WELLES,

Intern. Psychopathic Department, Boston State Hospital.

In the examination of cerebrospinal fluid post-mortem the Wassermann reaction is unreliable according to the consensus of opinion. Nor is the post-mortem cell count of great value. There remains the Gold Sol Test of Lange, which, if reliable, with post-mortem fluids would offer much in the way of differential diagnosis of syphilitic and other conditions of the nervous system. At the same time it would give an excellent opportunity to compare the reaction obtained with the existing pathological condition.

(It may be stated here that the test is performed by the addition of a preparation of colloidal gold to ten dilutions of spinal fluid, ranging from 1/10 to 1/5120, and the results read according to the change in color ensuing. Where no change occurs the reaction is called negative and recorded as 0. The color changes, depending on the amount of gold precipitated, are recorded as 1, 2, 3, 4, 5, the latter being clear, due to all the gold being flaked out.)

In the clinical application of the gold sol test it has been shown that different inflammatory processes of the central nervous system give reactions differing in the amount of color change and in the dilutions in which the color change occurs depending on type of condition existing. Thus syphilitic disease of the central nervous system characteristically gives a reaction in the first five dilutions, tuberculous meningitis, as a rule, tends to react in the middle dilutions, while the meningitides of pyogenic origin often show the reactions in the high dilutions. Further, general paresis usually gives a characteristic reaction differing from that of cerebrospinal syphilis or tabes. The table on opposite page illustrates typical reactions.

In summing up the experiences with this test in the laboratory of the Psychopathic Hospital (previous contribution)¹ the following conclusions were offered: "(1) Paresis gives very typical reactions, but cases of undoubted paresis may give atypical reactions and cases not paresis may give the type reaction. (2) We are unable

to offer any conclusions as to its value in the differentiation of cerebrospinal syphilis and paresis. (3) Tabes gives a reaction quite different from paresis, fairly characteristic of syphilis but not in itself diagnostic of tabes. (4) It is of no certain value in cases of congenital syphilis showing no other signs of central nervous system involvement. (5) Non-syphilitic cases give at times reactions in the so-called syphilitic zone (the first five dilutions). (1) In view of the above statement it can be maintained that a reaction in the syphilitic zone in cases of syphilitics does not necessarily argue syphilitic involvement of the central nervous system, all other signs being negative. (7) It would seem to offer a differentiation of tuberculous meningitis and is here at times more valuable than any other test."

These conclusions drawn from a series of 135 cases, as those by others who have reported their results, have depended in large measure on the accuracy of clinical diagnosis. It is evident that in any empirical test such as the gold sol, the final evaluation must depend on post-mortem confirmation.

In order to determine the significance of its results of this test with post-mortem fluids we tested the spinal fluids obtained post-mortem from the lumbar region in a series of twenty-six cases. These results we have analysed, comparing them with ante-mortem results and interpretations as indicated in the above summary. For analysis the cases of this series may be divided into five groups:

Group 1. In which the gold sol test was performed, both ante- and post-mortem.

Group 2. Cases of general paresis.

Group 3. Cases giving a negative reaction.

Group 4. A case other than general paresis giving the typical "paretic reaction."

Group 5. The remaining cases giving positive reactions of various sorts.

Group 1. Six cases tested both ante and post mortem. S. B. I. 1914, 58, 66, 71, 74, 79, and S. B. I. 1915, 2.

[illegible]

Of these six cases, the first two, representing general paresis and multiple sclerosis respectively, showed the same result with the gold sol test, ante- and post-mortem. The third, a case of cerebrospinal syphilis (post-mortem diagnosis) gives a very slight reaction in different dilutions before and after death. Such a light reaction is practically negligible from the clinical standpoint. The symptoms in this case were only of a few weeks' duration and the patient died in a convulsion; that is, we may consider a rapid change to have taken place in the central nervous system. This case is especially noteworthy in showing the value of the gold sol test

in the differentiation of paresis and cerebrospinal syphilis. There were marked mental symptoms resembling catatonic dementia precox. The Wassermann reaction in serum and fluid was positive; there were 109 cells per cubic mm. in the spinal fluid; the pupils were sluggish. In other words the picture clinically and serologically was that of general paresis. The gold sol test on the contrary was very different from the typical paretic reaction. Post-mortem examination showed the case to be cerebrospinal syphilis (Alzheimer criteria). This is the only case we know of in which the diagnosis of cerebrospinal syphilis has been confirmed post-mortem and in which a gold sol test has been performed.

The fourth case, in which there was a large infiltrating glioma of the brain, gives quite different results before and after death; but in this instance fluids withdrawn before death with an interval of three weeks also gave very different reactions. This change in reaction is occasionally seen in fluids drawn at intervals before death and has seemed to us to indicate that an active process is going on. So we are not surprised to find such a difference from a previous ante-mortem result occurring in a fluid obtained after death when there has been a period of time intervening.

The fifth case is one shown histopathologically to be general paresis; yet ante-mortem the gold sol test had not been typical (the color change of less than the usual intensity). The post-mortem gold sol result appears quite different from the ante-mortem or the paretic reaction, and resembles rather the reaction described as suggestive of cerebrospinal syphilis. As one watches the development of color changes in paretic fluids, it will be found, as a rule, that the color changes start in the fourth or fifth tubes; after an interval of a half-hour to an hour one will often find the reaction such as here given post-mortem, in this case at the end of the observation; while later at the time the test is read, i.e. at the end of twelve hours, the changes have gone on to characteristic paretic reactions. In other words such a reaction as here observed would correspond to an incomplete paretic reaction. The case in question was a rapidly fatal one, with the entire duration of symptoms less than three months; in other words a rapidly progressing process with very probably corresponding changes in the fluid.

The last case is one in which the diagnosis was Korsakow's polyneuritic psychosis. Myerson² has offered evidence to show that in this condition there is a change in the albumin content of the spinal fluid from the normal, and that the amount at least of the albumin varies during the progress of the disease.

It seems to us that these cases indicate that fluids obtained after death have undergone no change as far as their reactions with the colloidal gold are concerned, from their conditions immediately ante-mortem.

Group 2. *Seven cases of general paresis.*

Of these seven cases of general paresis the first four give typical "paretic reactions," while the remaining three give reactions which are not typical. Analysis of these three cases throws some light on the possible reasons for the deviation from the rule. The brain and various viscera from B. S. H. 1914.31 showed marked autolytic changes. Histologically there was a slight cerebral meningitis, the vessels were distended, particularly those in the cerebral white matter, and contained many polar staining bacilli. These were probably post-mortem invaders. There was some perivascular infiltration. This body was not kept under the best of conditions and was autopsied eight days post mortem. It seems probable that the autolysis led to the production of albuminous material not normally found. It suggests the problem of observing the changes in reaction of the fluid with the colloidal gold that may occur in autolytic and other lytic changes of the nervous system.

The second giving atypical results for paresis, S. B. I. 1914.88, was complicated with pulmonary gangrene. Whether this had any bearing on the results we are not prepared to say. S. B. I. 1914.79, as pointed out in the discussion under the preceding group, although an undoubted case of general paresis as confirmed histopathologically, failed to give a paretic gold sol reaction ante, as well as post mortem. This case tends to support the clinical observations as

mortem spinal fluid and when the body is well preserved or the fluid obtained early, the results are the same as would have been obtained just prior to death.

6. The gold sol test has the same value in the examination of cerebrospinal fluid obtained post mortem from the lumbar region as ante mortem, and the results may be similarly interpreted for diagnostic purposes.

ENCHONDROMA.

A REVIEW OF THE LITERATURE OF THIS SUBJECT WITH REPORT OF THREE CASES OPERATED UPON BY THE AUTHOR.

By LOUIS A. O. GODDUE, M.D., BOSTON.

Assistant Orthopedic Surgeon, Out-Patient Department, Massachusetts General Hospital; Orthopedic Surgeon, Mt. Sinai Hospital, Boston; Consultant Orthopedic Surgeon, Woonsocket Hospital, Woonsocket, R. I.

IN a review of the literature of this subject one is struck with the great diversity of opinion, and theories as regards etiology. Also, the difficulties of diagnosis and the many opinions regarding the conservative and radical treatment and prognosis are confusing. Necessarily treatment depends to a great extent on a number of conditions, and particularly upon whether the surgeon is a conservative or a radical man. In the older works on this subject the great preponderance of opinion leans to the view that this is a strictly benign growth, and up to the present time only a few men consider it more or less malignant in character.

Some writers state that a preponderance of osseous tissue makes it benign and gives it the character of an osteoma or exostosis, while others claim the presence of osteoid tissue makes it a malignant type. As regards the etiology of these tumors Virchow, Ziegler, Stengel, and others feel that they spring from remnants or islands of cartilage left in abnormal situations as the result of imperfect fetal development, and especially at the epiphyseal portion of the bone. They feel that rickets is a predisposing factor to the condition.

The three cases about to be described by the author were near joints, and the greater number of the cases looked up all occurred near the joints or at the epiphysis of long bones. Therefore, from this review one would be warranted in feeling that from a clinical viewpoint, at least, this was the most plausible theory.

Whether or not the tumor arises from the periosteum is still a question. Then, again, whether the hard cortex sometimes found is really a part of the tumor or whether it is simply an over-stimulated periosteum is a question.

These tumors are rarely pure cartilage, and even the small ones often show deposits of lime salts, which are easily seen at the time of operation, and they usually show, also, marked disintegration. As to the question of trauma being a factor in causing these growths, one can believe that it might possibly be an exciting cause, as in Case 2, described in this article. Von Recklinghausen has attributed the disturbance in bone formation, which gives rise to such growths, to imperfect development of the blood vessels with faulty nutrition, as the result of an imperfect vascular supply. Koch believes that cysts, which occur from time to time in long bones, frequently arise in enchondromata. Bloodgood states single and multiple central enchondromata are very rare, but undoubted examples have been reported.

Patients with these conditions almost always complain of swelling, and of inconvenience in motion, and not of pain, unless there is direct impingement on a nerve. However, as in Case 1, a very small nodule might occur very near a nerve, causing considerable pain. To make a definite diagnosis of enchondroma clinically is not always a simple task. We know that tumors developing in a young patient, and situated near the epiphysis are most likely either enchondroma or sarcoma. Sarcoma will usually give more clinical symptoms of a malignant growth; symptoms which are well known and definite when present. These growths are also much more rapid in their growth than enchondromata, therefore it seems that the clinical course of the growth would be rather an important factor in diagnosis. Enchondroma is, without doubt, of a very slow and insidious growth, and only when it interferes mechanically, or is large enough to be observed as a distinct tumor, are patients conscious of it. The general health is not impaired and subjective symptoms are absent.

It would seem that with the x-ray we have a fairly accurate adjunct in diagnosis. Cases 1 and 2 were diagnosed by Dr. Walter Dodd as enchondromata, and subsequent pathological examination, after removal, proved them to be such.

Dr. E. W. H. Shenton, of Guy's Hospital, states in a report that the radiograph easily distinguishes the tumor. He feels that one very important point is the very regular outline that we observe in these conditions, as compared with the irregular and ragged way that ossification takes place in malignant conditions.

The line between a benign and malignant tumor is not always a sharp, well-defined one. It would seem that the two classes are not distinct, but rather differ in degree. An apparently benign tumor may show characteristics gradually changing to malignant.

The fact that distinct enchondromata do recur after operations is no indication that the diagnosis is wrong. It seems to the writer that the two factors may enter into this condition. One is, as Bloodgood states, "An incomplete removal of benign tissue, with the exception of angioma, is always followed by re-formation of a tumor from residue left behind, and the chance of malignant change in the residue is greater than in the undisturbed benign lesion." The other condition is that which might be called a recurrence, but which may be due to a very small nodule overlooked at the time of examination. The writer feels that this was the fact in Case 1, where a small overlooked nodule grew, rather than a recurrence of the tumor took place after primary removal. As can be seen by the x-ray, it is only by extreme rotation of the arm in this case, that this small nodule situated in the musculo-spiral groove could be made out.

Treatment. All surgeons, of course, will readily agree that a radical removal is indicated. What to do with a border-line case is, of course, difficult to decide, but it would seem, when practicable, the patient should always be given the benefit of a conservative operation. In estimating whether or not the conservative treatment gives the desired result, we must, of course, see the difficulty of drawing conclusions from the results of a large number of surgeons, of varied technic and training, in this particular branch of surgery. It must be conceded that the surgeon most used to bone work is best able to cope with this condition.

In operations on this condition, the gross pathology gives a picture in experienced hands that leaves little doubt usually as to its diagnosis.

All surgeons know that very often the clinical picture of a condition does not coincide with the pathological picture. For instance, all orthopedic surgeons know, that they find knee joints which at time of arthrotomy show clinically a tuberculous lesion, but pathologically they give no indication of such a condition. These knees are followed, and later they come to excision, leaving no doubt as to their being typical tubercular knees, both by their clinical course and condition at time of excision. The writer believes that more and more, orthopedic surgeons are depending for diagnosis, in many of the bone lesions, on what their clinical experience teaches them.

In consideration of the above, and as Bloodgood further states, "In bone lesions the mutilation of amputation is so great and chances of a cure of any doubtful lesion, should it prove malignant, are so slight that the most conservative operation should be done."

The writer feels that the conservative operation is indicated in the great majority of cases.

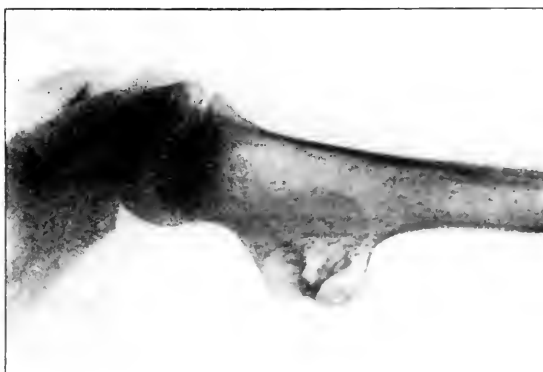

Virchow reports a case of enchondroma of the scapula, where the tumor was removed seven times, and the patient finally recovered. We must concede that the patient was far better off after seven conservative operations, still pos-

sessing his arm, than after the extensive radical operation of amputation. The author believes that the majority of surgeons are too quick to assume a recurrence of an operated tumor, as indicating malignancy. A simple recurrence in absence of other symptoms, as Virchow has shown, can do no particular harm, and conservative surgery is indicated. The loss of a limb means much to any individual, and the surgeon should be very judicious in his decision, in operating in these conditions. The majority of the cases when not too large, can easily be reached. The skin incision should be generous, and one will find that by very careful separation of the muscle fibres and rotation of the limb, the mass is readily reached without cross-cutting important structures.

Some authors have advanced the theory that these tumors start from the periosteum; the writer has a different opinion from some operators. A few surgeons state that the enveloping capsule can be opened and the enchondroma shelled out. The author cuts down when practicable, frees all the muscular attachments, does not open the capsule, cuts around the entire base of the growth, removing capsule and all. Some of these are very dense, and in order to be removed in toto, a sharp chisel and mallet are necessary. The base is then scraped with a very sharp bone curette and the whole cleaned thoroughly with 95% carbolic, followed by alcohol. The whole is covered as well as can be with fascia, then if the separation of the muscles has been done carefully, the fibres readily come together, and are held in place by chromic catgut and the skin closed with silkworm gut.

CASE 1. *Family History.* Negative. Age 11 years.

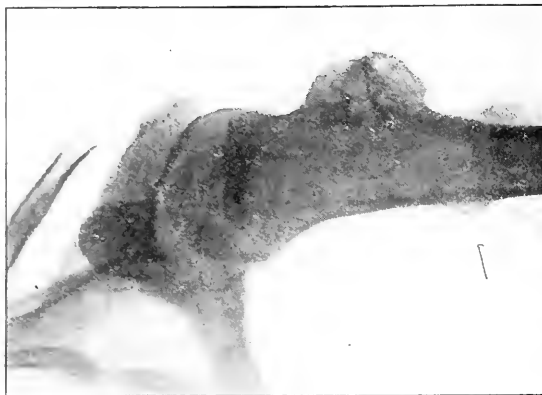

Past History. Child has always been well excepting tumor growth in the outer side of the right

CASE 1. PLATE 1.

Roentgen examination of right humerus. Plate reveals a tumor on the outer and posterior surface of humerus about one inch from the epiphyseal line. Roentgen diagnosis: Enchondroma. Dr. Wm. Dodd.

upper end of the humerus. Seen by the writer in consultation 20 months ago. Two years previous noticed a swelling of the right shoulder in about the middle of the deltoid muscle. Was seen by an eminent surgeon, who operated, and removed the growth; had been well for a period of 1½ years.

CASE 1.—PLATE 2.

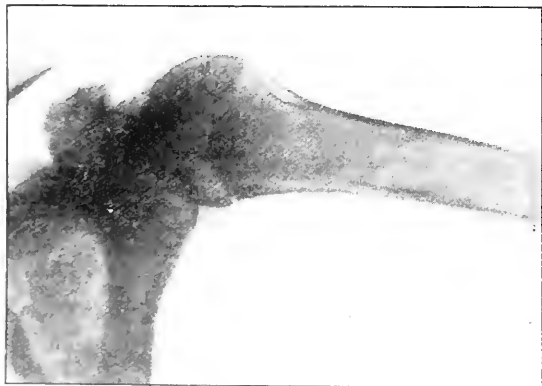

Arm in marked rotation showing second lesion on inner aspect of humerus. This plate illustrates the importance of taking all such cases in various positions. Arrow points to small nodule.

Dr. Wm. Dodd

CASE 1.—PLATE 3.

Same case taken by me twenty months after operation with arm in same relative position as two pictures of same case. It shows no pathological or abnormal condition.

Dr. Wm. Dodd.

when the swelling was again noticed, and thought to be at about the same location.

Physical Examination. At time patient was seen by the writer a large rounded mass, about the size of a case egg, was felt at about the region of the centre of the deltoid muscle. Small nodule also felt in the course of the musculo-spiral nerve; incision about four inches long had been made in the ex-

ternal posterior aspect of the arm. Case had been seen at one of the large institutions and had been advised to have arm amputated at the shoulder. Patient then seen by the writer, who advised x-ray and conservative operation for removal of the tumor.

Operation. Incision six inches long, beginning at the tip of the shoulder, made in the skin, fascia cut and the fibres of the deltoid muscle, at its upper portion, separated down to the tumor mass. The arm having been rotated outwardly, the base of the tumor was cut into with chisel; the arm then rotated inwardly, forcibly, the under border of the tumor was cut into in a similar way. The tumor was removed and base curetted and only a thin shell of good bone left. In order to reach the smaller tumor on the musculo-spiral groove, the arm was forcibly rotated inward, a careful dissection made between the external head of the triceps and the outer border of the deltoid, down to the nerve. The nerve located, held away by blunt dissector, and the small tumor, on the edge of the groove, easily made out, carefully recovered by very sharp curette. The parts replaced and the arm outwardly rotated. The base of the large tumor was then carefully covered with fascia, muscle fibres brought together with catgut and the skin closed with silkworm gut.

Uneventful recovery in ten days.

Pathological Report. Tumor shows a fibrous capsule, beneath which is a thick layer of relatively acellular cartilage. The cells become more and more abundant as the bone is neared, until at the edge of the bone, they can be seen in many places arranged in rows at right angles to bone, with in places masses of acellular material between them, in places, small finger-like processes of vascular tissue, in places along the drawing edge between the new formed bone, trabeculae. The marrow has been replaced by delicate connective tissue. Along the edge of the bone the whole suggests enchondromal bone formation. Diagnosis, enchondroma.

Rontgen Report. Two plates taken. One in abduction internal rotation, and the other in abduction, external rotation. About two inches from the articular surface of the right humerus, and on the inner side and posterior aspect, there is seen a distinct tumor. The appearance of this tumor would lead one to believe that it was of cartilaginous origin, as there are marked areas of increased density and others where the density is much less. This is probably an enchondroma. There is no evidence of periosteal sarcoma and it does not look, in any way, like a giant cell sarcoma. Diagnosis, probably enchondroma. Dr. Walter Dodd.

One year and eight months after operation, physical examination shows no palpable enlargements in region of previous growths; no pain, no disability whatever, patient constantly putting on weight, physical condition excellent.

As can be seen in x-ray the humerus shows no sign of operation but looks like a perfectly normal humerus.

CASE 2. P. A. Age 24. F. H. Negative.

Past History. At age of 16 noticed a lump at the outer and lower end of the femur. Noticed three weeks after playing football; x-ray in 1906, one year after injury showed a small cartilaginous outgrowth about the size of a walnut. Operation advised but refused. Tumor gradually grew larger, pained only after sitting down awhile in a cramped position.

Physical Examination. Fairly well developed

and nourished young man, a rather large, firm swelling felt about one inch external to the outer border of the patella; on motion of the lower leg definite snapping could be felt, no tenderness, operation advised.

Operation. Jan. 15, 1914. An incision about six inches long at antero-external aspect of the lower third of the thigh, and careful separation made down to the tumor mass. The tumor, as can be seen by x-ray, started from a small base, branched up-

CASE 2.—PLATE 1.

Internal lateral view shows a tumor somewhat anterior to the shaft. The character of the shadow indicates that it is made up of cartilaginous areas as well as areas of true bone. This plate shows the pedicle from which the tumor springs.

Dr. W. Dodd.

CASE 2.—PLATE 2.

Anterior view shows a tumor the base of which is one inch above the epiphyseal line, tumor is distinctly irregular and of irregular density. Roentgen diagnosis is enchondroma.

Dr. W. Dodd.

ward and outward. At the lower half of the tumor, the capsule of the knee joint seemed to be adherent; the tumor was therefore taken out in small sections by a Rongeur forceps and the capsule of the joint

carefully pushed forward, as portions of the tumor were removed. This was done in order that capsule of knee joint should not be opened unnecessarily. The entire base carefully curetted, swabbed out with 95% carbolic, followed by alcohol and muscles stitched up.

Discharged from the hospital in 10 days, wound healed. Weight bearing in three weeks, patient at present, twelve months after operation, states he never would have known he was operated upon, he feels so well, and all the former stiffness of the muscles that he had before operation had completely disappeared.

Pathological Report. Large, dense, bony and cartilaginous tissue from the femur measuring 4.5 x 4 x 3 C. M. Section disclosed large masses of cartilage, in which occur, in places, groups of young, closely packed cartilage cells. Elsewhere the cartilage exhibits necrosis, the cells either absent or showing only shadows of nuclei. The connective tissue received with specimen shows in places a high grade hyaline disintegration, the process not suggesting metaplasia of connective tissue into cartilage. Among the fragments occur masses of necrotic cartilage which have undergone autolysis. Diagnosis, Enchondroma of the Femur.

X-Ray Report. Case II, Plate 1. Anterior view shows a tumor the base of which is one inch above epiphyseal line, tumor mass is distinctly irregular and of irregular density. This tumor shows the distinct bony pedicle from which it springs. Plate II, Internal Lateral view shows same tumor and is somewhat anterior to shaft. Character of the shadow indicates that it is made up of cartilaginous areas as well as areas of true bone. Diagnosis Enchondroma. Dr. Walter Dodd.

CASE 3. Age 18.

Family History. Mother was in the Hospital five months ago for a goitre; father died of T.B. three years ago; history otherwise negative.

Present History. Has always been well.

Past Investigation. Five years ago, first noticed a lump on the inside of the arm, about the size of a marble. There was no pain at any time. The tumor grew steadily and upward, motion of the arm was limited more and more. The patient could not lift more than 50 pounds. On raising the arm there was no pain but there was a drawing sensation.

Physical Examination. Well developed and well nourished young man, rather apprehensive; no pain in motions of the arm; on palpation a tumor mass was readily felt in the axilla at upper end of the humerus.

Operation. An incision beginning at the tip of the coracoid process down along the inner border of the deltoid, to about the middle of the arm. A separation made between the two heads of the biceps, and dissection made down to the humerus; the whole arm rotated forcibly outward and the tumor readily presented itself. The tumor presented the usual smooth, shiny, cartilaginous appearance of these growths, was somewhat firmer than the usual enchondroma and readily removed. Contained areas of lime salts and necrosis. The tumor removed, base thoroughly curetted with 95% carbolic acid, followed by alcohol. The wound closed in the routine way. Patient discharged from the hospital in two weeks. At present, seven months from operation, has no inconvenience whatsoever. Pathological Diagnosis, Enchondroma.

THE STUDY OF DISTURBANCES OF THE STOMACH.

By H. F. HEWES, M.D., BOSTON.

[From the Clinic of the Massachusetts General Hospital.]

(Concluded from page 373.)

Here we have a symptomatology which is suggestive of hyperacidity, either simple hyperacidity, or ulcer with hyperacidity, the symptom complex of duodenal ulcer. The finding, however, is typical of chronic gastritis and showed a low acidity. X-ray examination here was negative, an argument for the absence of any organic cause for the gastritis. The stomach in reacting to disturbance of any kind is apt to give similar symptoms in very different types of disease or disturbance. With this fact in mind, and a knowledge that the most aggravated stomach symptoms, worse than those often seen in even advanced cancer, may occur as part of a neurosis, or as secondary to gall bladder trouble, syphilis, acidosis or anaemia, we should go very slowly in making a positive diagnosis of any special type of a stomach disease from the record of symptoms alone. The conditions which most commonly give a history of symptoms suggestive of organic stomach disease, are gall bladder trouble, appendix trouble, adhesions from old appendix or surgical operation, syphilis and nerve conditions. Often these conditions can be distinguished from actual stomach disease by the physical examination. If not the tube examination or the x-ray examination should make the distinction in many cases. In some cases of these outside conditions, abnormal findings by special methods, as hypersecretion, by tube, or incisure, or abnormality in peristalsis by x-ray similar to the findings in ulcer or cancer may occur. This is especially the case with adhesions involving the stomach. Here there is cause for confusion,

but though we may thus be confused in a positive way even with the use of our special methods of research between ulcer or cancer and outside conditions as causes of stomach trouble, we should not be confused where these findings are negative. Organic stomach disease should show some sign besides the record of symptoms, blood or stasis or hypersecretion or an abnormal sediment, by tube or abnormal feces findings, or abnormality of some kind by x-ray, one or the other, and it is a safe plan not to make a positive diagnosis without some such sign or some other definite physical sign, as a tumor or an extreme anemia.

A class of cases which has given me much trouble in the past, is the condition of stomach disturbance associated with neuroses or nerve debility. Often the symptoms in such cases are very aggravated. We find often a long duration of symptoms, with much vomiting and much loss of weight. Here the apparent nerve character of the patient may help diagnosis, but a more important factor is the absence of positive signs by tube or x-ray.

The ptosis cases are another class of difficult cases. Here also we find a lack of positive physical signs save the ptosis signs, which discriminate them from conditions of organic trouble. There have been too many of these nerve cases and ptosis cases operated upon in the past through lack of proper investigation of the case, and a faulty diagnosis. I do not mean to say that ulcer and cancer of the stomach do not exist without giving positive objective signs of some sort. There is doubtless a stage in all cancer cases where no sign is present, but since a history of marked stomach trouble is so common in conditions other than organic stomach disease it is a good plan to keep the rule of not going too far in diagnosis of organic conditions without objective signs.

Another danger in stomach work already emphasized by me, is seen in the misleading character of x-ray findings which occurs fairly often. As a result of my experience up to the present I am very slow to make a positive diagnosis of organic stomach lesion, in many cases by an abnormal x-ray finding alone, that is, when the abnormal x-ray finding is the only abnormal objective finding.

There are cases where we are safe in going by an x-ray finding plus a history without other objective findings, as, for example, where a clear diverticulum is present, or where a nine-hour bismuth residue with absent sphincter is present, but there are, as stated, many abnormal x-ray findings which in some cases actually represent the effect of cancer or ulcer, which may be present with no stomach lesion, or with other conditions. I have seen too many cases operated upon the verdict of the x-ray alone, when good judgment based upon a study of the case by other methods in addition to the x-ray, might have changed the diagnosis. Here is a case in point:

CASE 18. J. McN. Age 70. Since extraction of teeth nine months ago the patient has been bothered with excessive watery expectoration. He fills a pint cup in two hours. Within this period he has had distress and burning in epigastrium, often actual pain coming at once after meals and lasting one-half to one hour. Pain often radiates to right back. No nausea or vomiting. Bowels constipated. Loss of 33 pounds of weight in five months. He has lived on liquid food for months owing to the condition of his mouth which makes it impossible to wear plates.

Physical examination: Some tenderness in epigastrium. Hemoglobin, 75%. Wassermann negative. Blood pressure 150.

Tube examination: Fasting contents normal. Test meal contents: Free HCl, 0.2%. Feces negative.

X-ray examination: Well marked delay at the cardiac orifice, irregular outline of fundus. Constriction of mid-portion of stomach. Peristalsis absent on lesser curvature higher up. Conclusion: Extensive pathological process involving the cardia and lesser curvature. Carcinoma. Operation showed no lesion of stomach.

This case was submitted to operation on the ground of the very positive finding by x-ray examination. It was not a merely suggestive finding but one of what is usually considered a positive type. The out about the diagnosis was in the absence of any abnormal finding by tube in the fasting contents. Duodenal lesions unless causing blocking of the pylorus or hypersecretion, often show no abnormality of stomach contents. Old ulcer scars of the lesser curvature may show no abnormality, but it would be very unusual to have a malignant lesion of such extent as the x-ray finding suggested here with a normal tube finding. Many cells would be expected and possibly occult blood.

I have records of at least ten cases where a positive diagnosis of ulcer or cancer by the x-ray operator has led the physician to operate in the face of normal findings in other ways, or to neglect the study of the other aspects of the case, in which neither ulcer nor cancer was found.

The above is an extreme case. As a rule when a markedly abnormal x-ray finding is present some pathological condition is present either in the stomach or in the abdominal tract somewhere. As stated, adhesions are a common cause of x-ray findings similar to those found in cases of cancer or ulcer. Witness cases 12, 13, and 15. Mild abnormalities, as the presence of incisura, are, however, common without actual lesion. Sometimes a finding is present one day and absent the next. Sometimes it shows on some plates and not on others. All these facts incline us to the feeling that we must go very slowly in accepting the x-ray finding as absolutely diagnostic of such conditions, in many cases, unless supported by other strong evidence. This point of support by other findings is illustrated in Cases 14 and 15, in the first positively, in the second negatively.

A third point in connection with the study of stomach cases which has been much impressed upon me in my recent experience is the frequency with which two conditions, syphilis, and alcoholism, or constant use of alcohol, exist as the underlying cause of severe conditions of stomach trouble, suggesting in their symptomatology conditions of organic stomach trouble. Syphilis of the cord has proven capable of being a cause of severe stomach signs suggesting ulcer, in several of my cases. Other cases have had what were apparently actual specific lesions of the stomach. I make it a rule to have a Wassermann test made in all obscure stomach cases, or cases where there is reason in the history to suspect syphilis. In some cases an examination of spinal fluid is necessary, a blood Wassermann being negative, and a fluid finding positive.

Alcohol, particularly the long and constant use of the poison, can cause conditions of stomach trouble which simulate in symptomatology and often in objective findings, as findings of blood, gastritis, etc., conditions of organic stomach trouble. This phenomenon is so marked that I hesitate to make a positive diagnosis of ulcer or cancer of the stomach in a patient addicted to alcohol, whatever the findings.

Here is a case of cord syphilis illustrating my point:

CASE 19. H. P., age 34 years, Sept. 26, 1912. Well up to eleven months ago. Then one night after eating had an attack of severe pain, located to left of navel, radiating to ensiform, vomited twice with it, no blood in vomitus. Since then has had some pain or distress after every full meal. About three times a week the pain is very severe and vomits with it, may vomit once or twice with relief, at times about every hour for 24 hours. Has lost 35 lbs. in this period. If very careful of diet has attacks less often. After milk and crackers no distress, but always has some after full meal. Has now been vomiting about every hour for last two days.

Past History. Had an eruption and mucus patches and loss of hair about eight years ago. Treated for two years for syphilis.

Physical examination negative. No tabes signs in reflexes. Abdomen tender generally. No spasm.

Stomach: Fasting contents, 10 c.c., no food, no blood, no stasis. Test meal, HCl, 0.16%.

X-ray: Outline of stomach normal. Peristalsis, extra vigorous. Slight 6-hour residue. Adhesions of cecum. Wassermann negative in blood.

The patient was placed on careful diet. Improved and was sent home.

Nov. 14. Returned. Well up to one week ago, but as patient went back to regular diet began to have distress and vomiting, 15 minutes after meals. Four days ago at 2 p.m. severe pain in epigastrium which lasted 12 hours, with repeated vomiting. Same thing next day at 3. Since then vomiting for 48 hours. Relief for few minutes at a time. Vomitus consists sometimes of food, often of green fluid.

Examination: The patient's face suggests that he is in great pain. Urine gives strong acetone test. He vomits all food. Given glucose by vein; acetone cleared up and vomiting less, but still some pain.

It was decided with 6-hour residue of bismuth and history of vomiting food 24 hours old that duodenal ulcer might be present, especially as no Wassermann test was obtained, and operation was advised.

Operation showed adhesions of cecum. No gallstones, no ulcer. After operation, urine showed slight acetone, but patient did well. Home Nov. 20.

Jan. 9. After operation O.K. up to one week ago. One week ago, after supper, he had pain and vomiting every hour for 24 hours. Three days ago vomited a basin full of black fluid and since then he has had constant pain and some vomiting. Acetone present in urine and vomitus. The patient was given glucose by vein to reduce acidosis.

Jan. 13. Vomiting ceased. Another Wassermann negative.

Jan. 16. Spinal fluid examined, 420 cells, mostly lymphocytes. Wassermann on fluid positive. Given salvarsan on 17th. Vomited after this for 24 hours, then ceased. Second dose on 21st, third on 28th (intraspinous). No vomiting after 19th. Sent home.

This case was apparently syphilis of the nerve centres with reflex stomach symptoms of gastric crisis. The symptoms suggest organic disease of the stomach. The x-ray finding was abnormal but not diagnostic of ulcer.

Syphilis affecting the stomach may also occur as a definite syphilitic lesion of the stomach. Such cases may give all the signs of ulcer or cancer, including tube and x-ray signs. Where we have such a finding with a positive Wassermann on the blood, we should consider syphilis as the cause of stomach symptoms and give salvarsan for a period before deciding to operate upon the case.

I have seen several cases of ulcer of the stomach and one ulcer of the duodenum associated with a positive blood Wassermann. The cases were operated upon as no change in conditions occurred with salvarsan. Ulcers were found but as they were not excised the actual nature of the ulcers was not determined. It is quite possible of course to have a syphilitic ulcer which has formed chronic connective tissue scars which tissue would not yield to specific treatment, though the fresh ulcer might.

Here is a very remarkable case representing the effect of alcoholism in causing disorder of the stomach and is a type of disorder which cannot be distinguished from that caused by organic lesion of the stomach due to ulcer or cancer. This case also illustrates that hematemesis and positive blood findings are not always a sign of ulcer or cancer:

CASE 20. F. H., 44 years, May, 1911. For 3-4 years the patient has suffered from stomach symptoms, as a rule following spree of drinking. For a week after a spree he would have nausea, sometimes vomiting, and much dyspepsia. Between spells no dyspepsia.

December, 1910. After a protracted bout, vomited for two days. Noted black color to vomitus and was told by a physician that it was blood. He quit drinking and had no stomach trouble up to one

week ago. Then he began to suffer from weakness and dizziness. Noted that his stools were black. No dyspepsia. Came to hospital by advice of physician who said that he was passing blood in his stools.

Examination: Hemoglobin 40%. Physical examination negative.

Tube examination: Fasting contents, 10 c.c. of clear fluid, few blood corpuscles in sediment and faint guaiac test, but finding not distinctive, as the little blood might have been due to irritation of the tube. Test meal: Free HCl, 0.18%. Feces gave positive blood test.

X-ray plate showed irregularity of outline on lesser curvature, and 6-hour bismuth residue. Fluoroscope showed failure of peristalsis at lesser curvature. Discharged after one month, as all bleeding had ceased and he had regained his strength.

Sept 6. Was well after discharge until today, when he vomited a quart of blood. No pain or distress in stomach. X-ray showed some irregularity on lesser curvature. Two weeks later the patient was operated upon, on the possibility of ulcer of lesser curvature (x-ray finding) causing recurrent hemorrhages, though the diagnosis of varices as the cause of bleeding was strongly considered. No evidence of stomach lesion was found. Large varices about esophageal end of stomach. Liver appeared normal. Such possibilities as this are to be considered in cases where hematemesis is the symptom. As a rule, of course, the diagnosis of ulcer is safe in such cases. But where alcoholism is present I hesitate to make the diagnosis of ulcer.

The description of the methods of clinical study which are utilized in the investigation of stomach cases, and of the value of the findings obtained by the use of these methods for diagnosis, with the illustration of the method of procedure and general plan of drawing conclusions from clinical findings in individual cases contained in the report of case records, gives you a good general idea of the subject of the study of stomach cases for purposes of diagnosis.

To summarize the subject matter of this review, I append an outline of the value of the various clinical findings for diagnosis, in the various separate diseases or disturbances of the stomach and duodenum.

1. Fresh bleeding ulcer of the stomach. History: A typical history of this condition is one of a short history of dyspeptic symptoms, as distress soon or late after eating, with finally the vomiting of a quantity of fresh blood. Such a record does not, however, occur in all cases of this type. Also vomiting of blood may occur in cirrhosis or in cancer. Such a record is, however, as a rule sufficient for the diagnosis of ulcer of the stomach or duodenum without resort to further methods of investigation, as tube examination or x-ray examination.

Tube examination. Fasting contents show fresh blood in fair quantity or a dark colored content giving a marked blood test by chemical method.

Feces examination shows a blood test.

X-ray examination often shows no sign in

fresh ulcer. It may show incisura and extra vigorous peristalsis.

2. Fresh bleeding ulcer of the duodenum.

History may include vomiting of blood as with gastric ulcer, but often is simply a history of distress in the stomach coming long after eating and relieved by food. Sometimes there is acute pain and a tender point to the right and above the navel. Dizziness and faintness are not uncommon symptoms.

Tube examination may show blood, may show simply hypersecretion, may be entirely negative. Feces examination shows marked blood test. X-ray examination often shows no signs. In some cases irregularity of duodenal outline with extra peristalsis above or pylorospasm are seen.

3. Chronic ulcer of either the stomach or duodenum located at the pylorus or causing narrowing of this opening.

These cases may have a very typical, almost pathognomonic history as follows:

For a long period the patient has suffered off and on from dyspepsia. The symptoms are distress or pain coming, as a rule, long after eating. Symptoms sometimes relieved by food. There is often pyrosis and heartburn. Vomiting may and may not be a feature in the early part of the history. It may be of food or of acid fluid. The trouble may come by spells of a week or a month. In the intervals of a month or more there may be no symptoms. The spells get more frequent and more severe. Finally vomiting becomes a marked factor as contraction of the scar tissue begins to close up the pylorus. Vomiting gives relief for a time. Then dyspepsia returns, of moderate severity the first day, more on the second day until in from 24 to 48 hours from the vomiting there is acute distress and vomiting again. The amount vomited is large, a quart or two. This history is not found in all cases, but at the stage of closure of the pylorus vomiting of large amounts of food is always a feature.

Tube findings in these cases are typical. Fasting contents is of excessive quantity, 200 to 1000 c. c., and contains much food. Often sarcinae. Free HCl is present. A blood finding is rare. Test meal contents show free HCl, often in excessive amount, *i. e.*, hyperacidity. This is the finding in the final stage of constriction of the pylorus. In the earlier stages simply hypersecretion in the fasting contents, 60 to 150 c. c. of fluid, and hyperacidity with the test meal may be the findings. X-ray findings in the final stage are typical. There is a 9- to 24-hour bismuth residue, and absence of sphincter and cap. Peristalsis above pylorus is very deep and vigorous. Often no bismuth is seen to enter the duodenum. In earlier stages there may be simply a six-hour residue and a poorly defined sphincter and cap with extra vigorous peristalsis above.

4. Chronic ulcer of the stomach located in the curvature, or fundus or antrum, that is, located where it causes no blocking of the pylorus. The history in these cases varies greatly. It is often a history of general dyspepsia for a long period,

often intervals of freedom, but often continuous, such as may be found in hyperacidity or in nerve dyspepsia. Symptoms may be simply distress, and gas coming soon or late after eating. Vomiting may or may not be a feature. Pyrosis and heartburn may be present. Tube findings vary greatly in these cases. Fasting contents may show hypersecretion, 60 to 100 c. c. of clear acid fluid, with no food. Free HCl present. Blood is rarely found but may be. Often the contents is only 25 to 40 c. c. in amount. As a rule the sediment contains a large number of cells. Test meal contents as a rule show a high percentage of free HCl but may give normal findings.

X-ray findings vary greatly in these cases. Where the ulcer is penetrating or perforating, a large deep scar or diverticulum is seen. There is an area showing irregularity of outline where peristalsis is sharply checked, being vigorous above and below this point. On the wall opposite this region there may be spasmodic contraction, giving an incisura. Often there is a bismuth shadow outside the regular stomach outline. In callous or superficial ulcer the only sign may be an incisura opposite the seat of the ulcer. In some cases of this latter type the x-ray gives no sign of abnormality.

5. Chronic ulcer of the duodenum below and not directly involving the pylorus. These cases often give a typical history, viz:

Dyspeptic attacks over a long period, with intervals of complete freedom from symptoms. During the spells of trouble there is distress, often pain, coming long after eating and relieved by food. There may be pyrosis and heartburn. Real pain is often present, but may be absent. Vomiting may or may not be a feature. The vomitus consists as a rule of acid fluid without food, but may consist of food. The attacks are apt to recur on the advent of cold weather.

This history is always suggestive of duodenal ulcer but a similar history may occur in cases of functional hyperacidity, or adhesions, and of gastric ulcer. Many cases of duodenal ulcer do not give this typical history. Tube findings may show hypersecretion in the fasting contents. Often the fasting contents is normal in these cases. The test meal contents as a rule show an excess of free HCl. X-ray findings show as a rule in these cases a normal stomach outline and sphincter with irregularity of the duodenal cap or of the duodenum, and peristalsis of the stomach above the pylorus abnormally deep and vigorous. In some cases where the ulcer is penetrating, a diverticulum of the duodenal wall is present. Six-hour bismuth residue may occur.

The clinical picture in these cases depends greatly upon how much obstruction or functional spasm of the pylorus is caused by the ulcer. As stated, if the contraction scar actually narrows the lumen of the pylorus we may have actual food stasis by tube and marked bismuth stasis, with irregularity or absence of duodenal cap by x-ray. Ulcers below the pylorus do not cause

actual blocking but often cause spasmodic closure which may result in a finding of hypersecretion, fluid stasis but not food stasis, in the stomach and a six-hour bismuth stasis. Often in the latter type, however, there is no abnormality by tube and by x-ray, simply an irregularity of the duodenum and extra peristalsis above. This sign is always suggestive of ulcer but occurs equally with adhesions involving the duodenum and may be found where no organic trouble is present. A feature of the x-ray findings in these cases of duodenal ulcer may be an abnormally rapid emptying of the stomach in the early stages combined with a retardation of complete emptying—that is, a hyperistalsis with a six-hour bismuth residue.

6. Cancer of the stomach located elsewhere than at the pylorus, that is, not causing obstruction. The history in these cases varies greatly. In some cases there is a history of several months or a year of dyspepsia of indefinite type, loss of appetite, fullness or distress after meals, gas, combined with loss of weight and strength, a history which cannot be distinguished from that of nerve debility and other conditions.

In other cases there is a history of but a few months with a record of vomiting as almost the first symptom of the malady in the case, without any previous dyspepsia. Cancer symptoms are apt to be continuous when once started as contrasted with chronic ulcer symptoms which, save where there is contracture, are as a rule intermittent.

The tube findings show often a fasting contents of somewhat large amount, 30 to 50 c. c., containing a sediment of numerous broken down cells mixed with mucus. Often the positive blood test is present, but this is by no means a constant feature. Free HCl may be absent or present. Sometimes we get fresh blood or a coffee colored contents. These blood and cell containing contents are always suggestive of cancer, but can occur in ulcer or alcoholic gastritis.

Test meal contents may or may not show free HCl. The simple absence of free HCl in a test meal contents is not specially suggestive of cancer, but when such a finding is combined with evidences in the fasting contents findings as blood, or stasis, which mean either cancer or ulcer, this absent free HCl test meal finding is strong confirmatory evidence for cancer.

X-ray findings may show an area of stomach wall where peristalsis is lacking with a sluggish peristalsis over the whole stomach. This latter feature is a specially characteristic finding of cancer as against ulcer of the curvature where peristalsis is apt to be very vigorous above and below the area of absent peristalsis. Often the shadow of the affected area is very irregular and mottled or moth eaten. Sometimes a crater can be made out. It must be borne in mind that these characteristic findings of cancer, are some-

times obtained where no organic lesion of the wall is present, in adhesions, for example, or even with functional disturbances pure and simple. Also that the presence of cancer of the wall can be overlooked by x-ray examination, as it may be by tube examination. Feces finding may show blood, a finding which is rare in chronic ulcer though common, of course, in fresh ulcer.

7. Cancer involving the pylorus.

The history here may be one of gradually increasing dyspepsia symptoms coming finally to daily vomiting of large amounts of contents. Or the symptoms of vomiting after meals may come at the start of symptoms. Most cases have a short history of symptoms as contrasted with cases of ulcer of the pylorus, save the cases where cancer has formed on an old ulcer. Symptoms are, as a rule, continuous when once started. There is often much loss of weight and of strength. Anemia is often marked. Tube findings show in the fasting contents, large amounts of contents with food stasis. Blood may or may not be present, but is much more common in the condition than in ulcer at the pylorus, especially changed blood, discoverable by chemical test. Free HCl may or may not be present. Test meal contents may or may not show free HCl. Where this is absent with the stasis finding in the fasting contents the evidence is good for cancer against ulcer. Where it is present the trouble may be of either type. X-ray finding shows as a rule absence of sphincter and cap, with sluggish stomach peristalsis, as against the active peristalsis in ulcer. There is bismuth stasis, often nine-hour or twenty-four-hour stasis. Often an irregular moth eaten shadow of the wall is seen.

Feces findings often show blood. This is much more common in cancer than in chronic ulcer of the pylorus.

8. Adhesions involving the stomach or duodenum.

There is no definite type of history in this condition. Sometimes the record of symptoms is exactly similar to that described as a typical record of ulcer of the stomach or duodenum, viz, distress or pain coming long after food and relieved by food. Sometimes the story is one of an indefinite type, a dyspepsia similar to the history seen in some cases of cancer, in gall stones, constipation.

Tube findings are often negative in these cases but may be similar to those often seen in ulcer of the stomach, viz., hypersecretion and excess of free HCl. Sometimes with adhesions involving the duodenum we have hypersecretion. Adhesions rarely cause food stasis. X-ray findings may show good evidence of adhesions, viz., a stomach drawn to the right with extra vigorous peristalsis, or an irregularity or dilatation of the duodenum with extra vigorous peristalsis above the pylorus, the exact picture often given by duodenal ulcer. I have seen adhesions to the stomach give a picture by x-ray which was taken to mean cancer. The possibility of adhesions as

a cause of stomach symptoms suggesting ulcer has always to be considered. Differentiation may be difficult since both tube and x-ray may give signs with adhesions similar to those found in chronic ulcer. Adhesions not involving the stomach but affecting the intestines, as in cases of appendix trouble, or after surgical operations, often give stomach symptoms which are probably reflex effects. These conditions do not, however, give abnormal findings by tube or x-ray in the stomach or duodenum.

9. Chronic gastritis.

The history of symptoms in these cases is not of a definite type, save where there is a record of much use of alcohol. The stomach signs may be severe, as distress and vomiting, over a considerable period, or they may be simply symptoms of dyspepsia, as fullness after eating and gas eructations. Tube findings show a fasting contents over normal in amount of 40 to 80 c. c. consisting of a mucus filled fluid. The sediment often contains numerous stomach cells. Blood is rarely found in a simple gastritis. Free HCl is, as a rule, absent in an advanced chronic gastritis though traces may be present both in the fasting contents and the test meal contents. Tube findings are very definite for diagnosis in these cases. Gastritis is often an associate of cancer, but it often occurs as a disease by itself. X-ray findings are, as a rule, negative in chronic gastritis. They may show an atonic stomach with sluggish peristalsis. Feces findings are negative.

10. Ptosis of the stomach.

The history of this condition is not very definite. Many cases exist without stomach symptoms. Often the symptoms which are called stomach symptoms are intestinal symptoms or general symptoms of relaxations and low blood pressure. Tube findings are as a rule, negative. There may be delay in the emptying of the stomach, but it does not amount to twelve-hour food stasis. X-ray findings show a low stomach but are often otherwise normal. Six-hour bismuth residue may sometimes be present. Atonic peristaltic action may be present.

11. Hyperacidity of the stomach.

Where this condition exists as an independent condition, *i. e.* not as an associate of ulcer, we often get a history absolutely resembling the history of ulcer cases, both gastric ulcer and duodenal ulcer, *viz.* a long period of dyspepsia with distress or pain coming long after food with heartburn and pyrosis, sometimes with vomiting. The distress is often described as a gnawing sensation and is relieved by food. Spells of trouble are, as a rule, intermittent with periods of freedom.

Tube findings may show a fasting contents of 50 to 100 c. c. of clear fluid containing free HCl and no food or blood, *i. e.*, hypersecretion.

Test meal findings show an excess of free HCl in percentage. The fluid portion of the contents is large. Sometimes there is no fasting hypersecretion, simply a test meal hyperacidity.

X-ray findings, as a rule, show no abnormality in pure uncomplicated hyperacidity, as they commonly do when the hyperacidity is associated with ulcer. It is important to remember that though hyperacidity is a common symptom of ulcer, it does occur unaccompanied by the lesion.

12. Hypoacidity is a not uncommon condition. It may be an associate of cancer or chronic gastritis or atrophy, but it occurs in uncomplicated form. There is no definite history to these cases. Often the condition is discovered where no record of stomach symptoms is present. Tube findings show a normal fasting contents, absence of free HCl being a frequent normal finding in the fasting contents. The test meal contents show no free HCl.

13. Organic disease of the cardiac orifice and esophagus. Cancer at the cardia or just above in the esophagus may cause obstruction to the passage of the tube. The tube may bring up undigested food content, with no acid if there is obstruction here. If no food has been taken recently or if obstruction is not marked the tube may bring up mucous contents containing an excess of cellular elements. Often fresh blood is obtained.

X-ray in such cases may show retention of bismuth at the cardia, often dilatation of esophagus—sometimes the cancer shadow involving cardia with absence of contraction here.

Cases of cardiac spasm not due to organic disease of cardia may show tube findings of food or mucus as in organic trouble, but not the cellular content found often in cancer. X-ray shows retention and dilatation, but no shadow. Diverticulum may show clearly by x-ray examination.

A STUDY OF THE EFFICIENCY OF MIXED TOXINS (COLEY) IN INOPERABLE SARCOMA. A CRITICAL ANALYSIS OF 134 MICROSCOPICALLY PROVEN CASES.

By TORR WAGNER HARMER, M.D., BOSTON.

Assistant in Anatomy, Harvard Medical School; Junior Assistant Surgeon, Children's Hospital; Assistant in Surgery, Massachusetts General Hospital.

(Continued from page 377.)

CASE REPORTS.

ABDOMINAL WALL.

CASE 41. (Table, Case No. 110.) Case of Dr. M. E. Green. Small round cell sarcoma of the abdominal wall. A man of 20 with growth four inches broad extending from pubes to umbilicus.

Pathological Report. Small round cell sarcoma. After 60 injections of mixed toxins tumor disappeared. Patient in good health without recurrence four and a half years later. Recorded in Group F.

AXILLA.

CASE 42. (Case No. 8.) Small round cell sarcoma of axilla. J. G., 45, female. Shortly after an

incomplete operation to remove tumor in axilla, mixed toxins were started and continued several weeks. The mass was of several months' duration, invested axillary vein, and upon microscopical examination proved to be round cell sarcoma. No recurrence 7 years 10 months later. Recorded in Group F.

CASE 43. (Case No. 9.) Large round cell sarcoma of axilla. P. B., 67, male. Mass of glands in axilla of three years' duration, varying in size from a hazel nut to a walnut, in all $2\frac{1}{2} \times 3$ inches. Excised as much as possible. Operation incomplete. Toxin treatment immediately started and continued for about 7 months. Recurrence below clavicle 2 years later. During removal of same, axillary vein torn and sutured. Toxins resumed. Arm still swollen 4 months later. (Question of tied vein or recurrence.) Recorded in Group D.

GROIN.

CASE 44. (Table, Case No. 66.) Small round cell sarcoma of groin. Case of Dr. Tritch of Findley, Ohio. 62, male. Twice recurrent sarcoma of groin.

Pathological Report. Small round cell sarcoma. Toxin treatment for 3 or 4 months, with gradual and complete disappearance. Patient in good health without recurrence $1\frac{1}{2}$ years later. Recorded in Group F.

CASE 45. (Case No. 17.) Small round cell sarcoma of groin. E. C. B., 21, male. A mass in left groin of 3 weeks' duration, developing after a growth was excised.

Pathological Report. Small round cell sarcoma. Quick recurrence. Two months later toxin treatment started. Injections into tumor and buttocks with well-marked reactions. Maximum dose, 5 minims. Tumor practically disappeared, but recurred when treatment was less regularly given. Toxins resumed regularly with entire disappearance. Patient in good health without recurrence over 5 years later. Recorded in Group F.

CASE 46. Personal Case. Referred by Drs. D. F. Jones and Wyman Whittemore. Round cell sarcoma of the groin and pelvis. A. A. K., a Syrian of 25. House No. 194236. March 7, 1914, admitted with hard mass size of small grape fruit covering Scarpa's triangle on the left, and passing 2 cm. beneath Poupart's ligament. In places fluctuant, slightly movable and tender. This growth first noticed one year ago and remained size of peanut for two months. For past two weeks growth very rapid with constant pain.

March 8. Operation, Dr. Jones. Semi-circular flap turned inwards, exposing growth, which firmly invests femoral vessels. Incision carried above Poupart's and dissection made along iliac vessels retroperitoneally. Chain of glands felt extending far back in the pelvis. Eradication impossible.

Pathological Report (143-45). Dr. Whitney. Lymphoma. A tumor size of croquet ball with smaller nodules in a chain at one point. Soft, grayish homogeneous section. Microscopical examination shows structure of a lymph node with well marked follicles and great increase of pulp.

Recurrence steadily appeared and in a month, despite x ray treatment, filled Scarpa's triangle and extended above Poupart's into pelvis. This mass was firm, about $3\frac{1}{2}$ inches broad and 6 inches long.

Toxin treatment started April 9, 1914, and still

being given (now ten months). Injections into growth every second or third day. Maximum dose, 11 minims. Reactions often severe. At first there was marked softening and decrease in the size of the mass, then began to grow, producing considerable varicocele. Treatment, however, continued and a gradual diminution in size has occurred. Mass has several times ruptured and discharged. Now there is present, just below Poupart's a mass about $1\frac{1}{2} \times 1$ inches, and another above Poupart's apparently distinct from the first, which evidently extends into the pelvis, seems about size of small egg. The patient is in excellent flesh and color. Recorded in Group E.

INTRA-ABDOMINAL.

CASE 47. (Case No. 48.) Round cell sarcoma of omentum, ascending colon, small intestine and liver border. E. J., 23, female. Laparotomy discovered an inoperable mass involving above-named structures.

Pathological Report of Section. Round cell sarcoma. Toxin treatment continued for about 5 months. Injections alternately into abdominal wall and buttocks. Patient in good health without evidence of recurrence 12 years later.

CASE 48. (Table, Case No. 1.) Spindle cell sarcoma of cecum, omentum, and mesentery. Case of Dr. Mynter. Laparotomy discovered inoperable growth involving above-mentioned structures.

Pathological Report. Spindle cell sarcoma. Toxin treatment for two months, with entire disappearance of mass. Patient well 4 years later. Recorded in Group F.

CASE 49. (Table, Case No. 8.) Inoperable spindle cell intra-abdominal sarcoma. Case of Dr. H. L. Williams, Rochester, N. Y. A woman with an intra-abdominal mass. Section removed.

Pathological Report. Spindle cell sarcoma. Treatment one month with mixed toxins with entire disappearance of mass. Patient well 17 years later. Recorded in Group F.

CASE 50. (Table, Case No. 35.) Recurrent intra-abdominal spindle cell sarcoma. Case of Dr. Zabriske, Greenfield, Mass. A woman of 40. Attempted removal of intra-abdominal growth followed by recurrence.

Pathological Report. Spindle cell sarcoma. Treatment with unfiltered toxins for one year with disappearance of mass. Patient well 12 years later. Recorded in Group F.

CASE 51. (Case No. 49.) Round cell sarcoma of iliac fossa. R., 55, male. At exploratory operation a mass the size of two fists of six months' duration was discovered deeply seated in right iliac fossa. Section removed.

Pathological Report. Round cell sarcoma. Toxin treatment with intervals of rest for about a year with almost complete disappearance. Patient well one year later. Recorded in Group E.

CASE 52. (Case No. 18.) Round cell sarcoma of small intestine mesentery and glands. W., 25, female. Exploratory laparotomy discovered tumor size of fist, involving above-mentioned structures. Section removed.

Pathological Report. Round cell sarcoma. Toxin treatment started in one month and continued over 4 months. The mass had disappeared, but symp-

toms of local peritonitis developed (due to necrosis of tumor), and a fecal fistula developed. Patient recovered temporarily but recurrence ensued with death in a few months. Recorded in Group C.

PELVIS.

CASE 53. (Table, Case No. 14.) Inoperable round cell sarcoma of pelvis. Case of Dr. Packard of Boston. 15, female. Pelvic mass which proved inoperable.

Pathological Report of Section. Round cell sarcoma. Treated with unfiltered toxins for a few weeks with disappearance of mass. Patient well 33 months later. Recorded in Group F.

CASE 54. Personal Case. Referred by Dr. S. J. Mixer. R. B., young man.

August 6, 1912, Dr. Mixer enucleated a retro-peritoneal mass from the pelvis the size of a fist. The boy's body showed many large brown spots (congenital). In the right thigh just below Scarpa's triangle a hard, nodular, somewhat tender tumor, 2 x 3 x 1 inches. Many other smaller masses scattered over extremities and trunk. Two large masses and one smaller mass were excised.

Pathological Reports (Dr. W. F. Whitney). 1. A small fibro-neuroma of the leg. 2. A large 10 x 3 cm. myxo-fibroma of the leg. 3. A lobulated, firm mass 14 x 6 cm. from the pelvis, a large spindle cell sarcoma. "It is interesting to find these three types of growth, the last two probably degenerative forms of the generalized fibro-neuromatosis. (Von Recklinghausen's disease.)"

For 8 months progressive gain in strength and weight.

June 10, 1913, operation by Dr. Mixer. Cecum and lower sacrum removed, permitting the shelling out of a mass in several lobes. A mass higher up could still be felt. Through an abdominal incision this growth was found to be the size of a small orange, but its removal was thought inadvisable.

Pathological Report (Dr. W. F. Whitney). Lobulated tumor masses together the size of a fist. On section they were soft, homogeneous and of grayish color. Microscopical examination showed interlacing bundles of large spindle cells. The blood channels had little else for walls but tumor tissue. Spindle cell sarcoma.

The boy's suffering prior to and after this operation was excruciating. Morphia in doses of $\frac{1}{2}$ to $\frac{3}{4}$ grains was necessary every few hours. In addition, during the 24 hours he received phenacetine, aspirin, codeia, and cannabis indica.

Toxin treatment started June 25, 1913. Injections into abdomen daily, then every other day, then every third day, for $5\frac{1}{2}$ weeks. Maximum dose, 18 minims. Despite severe reactions recurrence rapidly occurred and patient died Nov. 19, 1913.

The toxins gave striking relief of pain for several weeks after their institution. Only small doses of morphia were occasionally necessary.

UTERUS.

CASE 55. (Case No. 67.) Recurrent round cell sarcoma of uterus. McM., 50, female. Removal of large pelvic tumor one year ago.

Pathological Report. Round cell sarcoma. A recurrence which infiltrated the whole pelvis developed, producing bladder symptoms. Toxin treatment started and continued for $2\frac{1}{4}$ years (118 injections). During two weeks the treatment was

stopped followed by return of severe pain. When toxins resumed, pain ceased. Mass entirely disappeared. Patient well 4 years later. Recorded in Group F.

CASE 56. (Case No. 66.) Malignant leiomyoma of uterus. Mrs. X., 42. Hysterectomy for large tumor.

Pathological Report. Leiomyoma. Recurrence within a few months, filling pelvis and apparently involving bladder. Its outline was irregular and consistency hard. Suffering great. Mixed toxins treatment with intervals of rest for 3 years. Pain ceased, mass became progressively smaller and softer and finally disappeared. Three years 11 months after treatment stopped patient in splendid health, and showed on examination little more scar tissue than is natural to hysterectomy. Recorded in Group F.

CASE 57. (Case No. 5, p. 142.) Mixed cell sarcoma of uterus. Case of Dr. J. M. Hundley, of Baltimore. Mrs. A. C., 38. Hysterectomy for infiltrating ovarian tumor size of fetal head.

Pathological Report. Round and spindle cell sarcoma of uterus. In less than a month recurrence firmly fixed to pelvic wall. Toxin treatment started and continued for 33 injections into cervix. Tumor disappeared in 8 months. Patient in good health without recurrence 9 years later. Recorded in Group F.

CASE 58. (Table, Case No. 39.) Mixed cell sarcoma of uterus. Case of Dr. J. C. Willy, New Orleans, La. Woman of 40. Toxin treatment started for large inoperable sarcoma of uterus. Continued with intervals of rest for 5 years. Mass nearly disappeared so that patient was able to get about and perform her regular duties. Went to Europe 6 years later. Recorded in Group E.

CASE 59. (Case No. 71.) Spindle cell sarcoma of uterus. Mrs. S. F., 42. Laparotomy was performed for removal of large pelvic tumor. This was seen to arise from the uterus, but was so extensively adherent that its removal was abandoned. Section taken.

Pathological Report. Edematous leiomyoma. Toxin treatment started and continued for 8 months. Injections into gluteal region. Reaction marked. Mass diminished in size and became more mobile. Second operation then performed. Very extensive.

Pathological Report. Spindle cell sarcoma. Two years later patient perfectly well without evidence of recurrence. Recorded in Group E.

OVARY.

CASE 60. (Table, Case No. 72.) Spindle cell sarcoma of ovary. Case of Dr. F. L. Tosier, Washburn, Maine. Woman of 22. Exploratory laparotomy revealed an inoperable mass arising from the ovary. Section removed.

Pathological Report. Spindle cell sarcoma. Toxins continued for 3 months with entire disappearance of mass. Patient in good health 4 years later. Recorded in Group F.

CASE 61. (Case No. 74.) Inoperable round cell sarcoma of ovary. Mrs. E., 26. A fixed mass, which filled pelvis and extended to umbilicus, was

found at laparotomy to be a nodular, dark bluish-white, vascular, very adherent tumor arising from ovary. Section removed, abdomen closed.

Pathological Report. Angiosarcoma. Toxins started in about 2 months and continued for 3 months (47 injections). Progressive decrease in size and increase in mobility. Second operation then performed. A freely movable mass size of a child's head with small pedicle easily removed.

Pathological Report. Round cell sarcoma. Necrotic. Healthy child subsequently born. One year 8 months after toxins stopped, death from acute pneumonia. No evidence of recurrence. Recorded in Group E.

CASE 62. (Case No. 72.) Recurrent inoperable mixed cell sarcoma of ovary. M. C., 16. Large tumor of left ovary removed.

Pathological Report. Round and spindle cell sarcoma. In 3 months an inoperable recurrence discovered at laparotomy. A retro-peritoneal tumor filling pelvis and lower abdomen. Toxin treatment. Reactions often severe. No mass evident one month later. Toxins continued. Patient ran a slight temperature attributed to absorption of broken down tumor. Died 22 months after first operation. Recorded in Group C.

CASE 63. (Table, Case No. 93.) Recurrent round cell sarcoma of ovary. Case of Dr. Porter, Fort Wayne, Ind. Woman of 40. After operation developed inoperable recurrence in pelvis. Toxin treatment for 2 months with disappearance of mass. Recurrence 4 years later not controlled by toxins. Recorded in Group C.

KIDNEY.

CASE 64. (Case No. 6, p. 143.) Round cell sarcoma of kidney. Case of Dr. H. K. McDonald, Halifax, N. S. M. P., 27, female. Incision in loin disclosed tumor of kidney adherent anteriorly to a larger growth. Section removed. Laparotomy revealed large inoperable retro-peritoneal mass.

Pathological Report. Round cell sarcoma. Toxin treatment started in two weeks and continued for about a month with disappearance of tumor. One year later in good health without evidence of recurrence. Recorded in Group F.

CASE 65. (p. 146.) Hypernephroma. Case of Mr. Arthur Connell, Sheffield, England. M. W., 37, female. Mass of 4 years' duration in right loin with hematuria. Operation from behind disclosed irregular tumor of kidney. Section removed.

Pathological Report. Hypernephroma. Two weeks later transperitoneal nephrectomy. Huge recurrence 4 months later. Toxin treatment for 4½ months with disappearance of tumor. One year later in good health without evidence of recurrence. Recorded in Group F.

CASE 66. Personal Case. F. M., 40, male. Referred by Dr. C. G. Mixer. On May 25, 1913, Dr. Mixer opened a large perinephric abscess through an incision in left flank. After ten ounces of pus had been evacuated a mass larger than a grapefruit still persisted towards median line. Section removed.

Pathological Report (Dr. W. F. Whitney). Sarcoma of kidney involving lumbar muscles.

Toxin treatment started June 15 and continued by Dr. E. H. Baxter of Hyde Park under my direc-

tion until Aug. 26 (10 weeks). Maximum dose, 16 minims. Reactions often severe. Five and one-half months after toxins discontinued there still existed a constantly discharging sinus in the flank leading to a mass much reduced in size, not tender and causing no discomfort. He has gained 50 pounds since operation. This small persisting mass may be purely inflammatory residue or a temporarily quiescent sarcoma. He refuses further operation. Recorded in Group E.

BONE (not giant cell).

CASE 67. (*Annals of Surgery*, November, 1914, Case 6, p. 540.) Periosteal round cell sarcoma of femur. 58, male. Condition regarded by Dr. W. J. Mayo too advanced even for hip amputation. Toxin treatment with entire disappearance. Patient well 5 years later. Recorded in Group F.

CASE 68. (*Annals of Surgery*, November, 1914, p. 562.) Round cell osteo-sarcoma of humerus. A. C., 31, female. An extensive growth of the upper humerus, tip of coracoid and glenoid cavity was curetted as much as possible. Mixed toxins started.

Pathological Report. Round cell osteo-sarcoma. Treatment continued 3 or 4 months with entire disappearance of growth. Four years later no trace of sarcoma. Working as house-maid. Fourteen years after treatment right cerebral hemorrhage with almost complete unilateral paralysis. No trace of sarcoma. Recorded in Group F.

CASE 69. (Case No. 66.) Large round cell sarcoma of spine with metastasis in lower jaw. C. E. C., 27, male. Operation was performed for tumor of lower lumbar region the size of two fists.

Pathological Report. Large round cell sarcoma. Within 2 months huge recurrence with depressed unhealed area 6 x 8 inches. The lower jaw presented a growth involving the entire horizontal ramus. Toxin treatment in gluteal region (49 injections). Maximum dose, 8 minims. Softening of jaw and back tumors occurred. Wound healed. Tumors disappeared. Five years and 3 months later patient well and without evidence of recurrence. Recorded in Group F.

CASE 70. (Case No. 43.) Spindle cell sarcoma of spine. S., 44. An incomplete operation for growth of spine followed by inoperable recurrence.

Pathological Report. Spindle cell sarcoma. Toxin treatment for two months. Injection into tumor and at a distance. Mass entirely disappeared. Patient well 8 years later. Recorded in Group F.

CASE 71. (Table, Case No. 64.) Mixed cell sarcoma of superior maxilla. Case of Dr. Lillenthal. 20, female. An excision of superior maxilla failed to eradicate growth.

Pathological Report. Spindle cell osteo-sarcoma. Mixed toxins were started and continued several months. Patient well two years later. Recorded in Group F.

CASE 72. (Case No. 9, p. 147.) Round cell sarcoma of superior maxilla with metastases. Case of Dr. O. K. Winberg, Lake Park, Minn. A. Y., 41, male. Four weeks after being struck by horn of steer developed tumor of superior maxilla. Resection of upper jaw did not eradicate disease and re-

currence developed. Swelling of abdomen and joints ensued, also metastases in axilla. Toxin treatment for 5 months (103 injections) with disappearance of jaw tumor and axillary growth. No evidence of recurrence 6 years later, when he died from acute nephritis. Recorded in Group F.

CASE 73. (Table, Case No. 85.) Round cell sarcoma of inferior maxilla. Case of Dr. F. R. Calkins, Watertown, Ill. Boy of 12. At operation it was found impossible to eradicate malignant growth of lower jaw.

Pathological Report. Round cell sarcoma. Toxin treatment for 4 months. One and one-half years later boy in good health without recurrence. Recorded in Group F.

CASE 74. (Case No. 23.) Round cell sarcoma of radius. F. S. 25, female. Exploratory operation upon a growth involving the lower end of the radius of 6 or 7 months' duration, revealing on microscopical examination round cell sarcoma. One week later this growth involved about 3 inches of radius and presented a fungating mass at site of recent incision. Toxin treatment instituted in 3 days and continued 6 weeks. Maximum dose, 5 minims. Reaction marked. Growth entirely disappeared in 3 weeks. Two years and 9 months later patient perfectly well. Recorded in Group F.

CASE 75. (Case No. 37.) Recurrent spindle cell sarcoma of tibia. W. F., 27, male. Canadian farmer. Two efforts at removal with curetting of bone were followed by recurrences.

Pathological Report. Spindle cell sarcoma. Toxin treatment started when a mass at junction of middle and upper thirds of tibia was 3 x 4 inches in extent and ulcerated. Treatment continued for 2 months. Tumor rapidly disappeared. While bone cavity was healing developed a severe attack of erysipelas. Healing complete 2 or 3 weeks later. Fourteen years after treatment discontinued, patient in excellent health with sound and useful leg. Recorded in Group F.

CASE 76. (Case No. 22.) Recurrent inoperable spindle cell sarcoma of iliac fossa. Mrs. D., 40. Exploratory laparotomy revealed an inoperable mass in the right iliac fossa size of a cocoanut, attached to ilium and abdominal wall. Section removed.

Pathological Report. Spindle cell sarcoma. Toxin treatment for 6 weeks with entire disappearance of mass. Recurrence of mass extending from crest of ilium to median line and to above umbilicus. Toxin treatment with intervals of rest for 3 months with marked diminution in size. About 3 months later mass had increased considerably. Toxins resumed and continued for 7 months. Tumor entirely disappeared. Twelve years after treatment patient in good health with no traces of the tumor. Recorded in Group F.

CASE 77. (Table Case No. 100.) Chondro-sarcoma of ilium. Case of Dr. William Tietz, Spangle, Washington. 34, male. Toxin treatment instituted for mass size of child's head arising from ilium. *Pathological Report* had been chondro-sarcoma. Treatment continued for 5 months with entire disappearance of growth. Patient well 1½ years later. Recorded in Group F.

CASE 78. (Case No. 32.) Recurrent spindle cell sarcoma of metatarsal bone. F. K., 16, female

Growth developed on foot after injury. Third and fourth metatarsals were removed. After a second injury to foot recurrence quickly developed. Foot amputated at ankle joint. The following year a recurrence appeared after an injury to the stump, followed quickly by metastasis in popliteal space. This became size of child's head and was removed. Mixed toxins started for tumor of stump. This entirely disappeared but was followed in 18 months by recurrence both in stump and popliteal space. High amputation (just below trochanter) was followed by recurrence in buttock. An attempt to remove this was unsuccessful. Toxin treatment resumed and continued with intervals of rest for 3 years. Growth disappeared. Patient well 10 years later. Recorded in Group F.

CASE 79. (Case No. 29.) Spindle cell sarcoma of sternum. Mrs. G., 38. Tumor of upper sternum involving articulation of clavicle, size of one-half an egg. Section removed.

Pathological Report. Spindle cell sarcoma. Toxin treatment for ten months. Reaction marked. At first tumor increased in size and metastases appeared in neck. Growths later softened, broke and finally disappeared. Maximum dose 30 minims (largest dose in Coley's experience). Four years later death from another cause with no evidence of recurrence. Recorded in Group F.

CASE 80. Personal Case. Referred by Dr. W. J. Mixer. Multiple leiomyomata. A. F., female, 55.

Back has always been weak since injured by sled when a child. Fifteen months ago "eleven lb. fibroid-uterus" removed by another surgeon. Seven months ago "small fibroid" removed from sacro-iliac region. For six weeks terrific pain between scapulae. For three weeks pain and progressive weakness of legs. For ten days walking impossible.

Back presents kyphosis and lateral scoliosis of fourth to tenth dorsal vertebrae, and numerous subcutaneous masses (question neurofibromata) one chestnut size opposite seventh cervical vertebra and one walnut-size over sacrum. Right leg can be moved only with great effort. Knee jerks, Babinsky and Oppenheim reflexes all present and extremely active. Right ankle clonus greater than left. Retention of urine, and occasional incontinence of feces.

Dec. 6, 1914. Removal of tumor over sacrum for diagnosis. Pathological report, probably leiomyoma.

Dec. 8. Removal of tumor of right shoulder. Pathological report, leiomyoma.

Dec. 10. Dr. Mixer performed laminectomy at sixth cervical to third dorsal; dura not opened. Upon retracting cord tumor mass visible extending anteriorly and passing above cord in saddle fashion. This growth was of infiltrating character, had invaded marrow of the vertebrae and pleural cavity through one intercostal space. Excised as thoroughly as possible with removal of considerable bone from body of vertebra and first rib. Impossible to eradicate growth. Pathological report, Dr. Whitney, spindle cell sarcoma.

Dec. 11. More power in right leg, and has voided normally.

Dec. 12. Legs better but weakness of left arm.

Dec. 15. Left arm improved but right arm weaker, cannot be raised but can be flexed.

Toxin treatment started Dec. 21, and still being given, now eight weeks. Injections into abdomen. Reactions mild. Maximum dose 23 minims. Progressive increase in strength of legs, arms slowly

improving, can walk with assistance. Recorded in Group E.

CASE 81. (Case No. 38.) Inoperable sarcoma of spine involving brain. Baby boy of two years nine months. Tumor of upper spine with paresis of both arms. Exploratory operation showed tumor arising from cervical vertebrae. Section removed.

Pathological report. Fibrosarcoma. Toxin treatment instituted and was still (over two years) in progress when case reported. Maximum dose, 6 minims. Good reactions. After eight months movements of hands and power to hold up head returned. Legs still practically useless. Recorded in Group E.

CASE 82. (*Annals of Surgery*, Nov., 1914, Case XV, p. 541.) Periosteal round cell sarcoma of femur. Case of Dr. Wilmuth of Louisville, Ky. Under toxin treatment tumor of femur practically disappeared. Patient apparently well 18 months later. Recorded in Group E.

CASE 83. (Case No. 40, p. 70.) Round cell sarcoma of femur (periosteal.) H. K., boy of ten. Pain of increasing severity in left leg for several months, when fusiform enlargement of entire left femur $6\frac{1}{2}$ inches long and within $2\frac{1}{2}$ inches of either extremity was discovered. Section removed.

Pathological report. Small round cell sarcoma. Gradual diminution in size. Fifty-seven injections. Maximum dose, 11 minims. Tumor disappeared in a year but shortly afterwards metastases occurred in both orbits and boy died in a few months. Recorded in Group D.

CASE 84. (Table Case No. 34.) Recurrent small round cell sarcoma of superior maxilla. Woman of 29. Had been operated upon for tumor of upper jaw; eradication impossible. Recurrence developed which involved the orbit.

Pathological report. Round cell. Daily injections into tumor for five weeks. Maximum dose 12 minims. Entire disappearance by sloughing. Fourteen months later no local recurrence but probably metastasis in tibia. Recorded in Group D.

CASE 85. (Case No. 31.) Periosteal spindle cell sarcoma of humerus. M. L., 35, male. Spiral fracture of left humerus. X-ray showed no growth. Two weeks later growth at site of fracture which increased rapidly in size. Several months later an exploratory operation showed growth involved upper third of bone. Central portion of growth curetted.

Pathological report. Spindle cell sarcoma. Toxin treatment in a few days and continued for 18 months. Marked diminution in size and immediate cessation of pain. Spontaneous union of pathological fracture in a few weeks. Despite several curettings growth persisted and finally shoulder joint amputation performed. Six months later metastases in pectoral region removed and toxins resumed. Two years later patient in good health. Recorded in Group C.

(To be continued.)

Book Reviews.

Guiding Principles in Surgical Practice. By FREDERICK EMIL NEEF, B.S., M.L., M.D. New York: Surgery Publishing Company. 1914.

Dr. Neef has, according to his own statements, undertaken the tedious task of formulating a system where there was none. It is an attractive little volume of somewhat less than 200 pages. Although he limits his title to General Principles, he goes into accurate and satisfactory details in all applications of these principles, at least in so far as the principles are those applicable to the surgical operative attack, the preparation for this attack and its after treatment. He has reduced things to their simplest essentials and avoids unnecessary elaboration. In his chapter on Anesthesia, after referring to reasons for displacing chloroform by the less toxic ether, he adds, "chloroform has not yet been displaced." Upon this point we could hardly agree for with the exception of the exigencies of war and in the tropical countries, chloroform has been displaced to a very considerable degree, and is being constantly displaced more and more. Local anesthesia, spinal anesthesia and anoci-association are not considered. The book is interesting and pleasant to read. Marginal notes in red ink attract the eye, and on the whole are an addition to the mechanical structure of the book. With so many large text-books at hand containing long chapters upon surgical principles, it may happen that Dr. Neef's volume will not attract the attention it merits.

Operative Surgery. The Head and Neck, the Thorax and the Abdomen. By EDWARD H. TAYLOR, M.D., B.S. (Dub. Univ.), F.R.C.S.I.; Professor of Surgery in the University of Dublin; Surgeon to Sir Patrick Dun's Hospital. New York: William Wood and Company. 1914.

It would seem as if there existed at present a sufficient number of worthy text-books on the subject of operative surgery; yet the more we examine Taylor's book, the more we must acknowledge that it justifies its existence, and that it has added a literally beautiful book to our surgical library. The plates, whether they are diagrams, outlines, photographs, half-tones, or color plates, are extremely fine. They justify superlatives. The book comes from the pen of an Irishman and covers only the operative procedures most frequently required in general surgical practice upon the head and trunk. Surgical anatomy preceding the various sections is concise, but adequate. At the end of the sub-divisions of the chapters are valuable and always suggestive comments. Excellent use is made of the varying sizes and styles of type in headings and sub-divisions of the text. The book is a large one in appearance, although as a matter of fact it contains but 500 pages. It produces a most favorable impression on the reviewer, and on account of the unusual combination of brevity, the high level of illustration and the extensive experience and undoubted ability of its author, it should become a favorite reference book in America.

THE BOSTON Medical and Surgical Journal

An independently owned Journal of Medicine and Surgery, published weekly, under the direction of the Editors and an Advisory Committee, by the BOSTON MEDICAL AND SURGICAL JOURNAL SOCIETY, INC.

THURSDAY, MARCH 18, 1915.

EDITORS.

ROBERT M. GREEN, M.D., *Editor-in-Chief.*

WALTER L. BURRAGE, M.D.
FREDERICK T. LORD, M.D. *For the Massachusetts Medical Society.*

COMMITTEE OF CONSULTING EDITORS.

WALTER B. CANNON, M.D. ALLAN J. McLAUGHLIN, M.D.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States. \$6.56 per year for all foreign countries belonging to the Postal Union.

The editor will be in the editorial office daily, except Wednesday and Sunday, from twelve to one-thirty p. m.

Papers for publication and all other communications for the Editorial Department should be addressed to the Editor, 126 Massachusetts Ave., Boston. Notices and other material for the editorial pages must be received not later than noon on the Saturday preceding the date of publication. Orders for reprints must be returned in writing to the printer with the galley proof of papers. The Journal will furnish the first one hundred reprints for half the cost price.

All letters containing business communications, or referring to the publication, subscription, or advertising department of the Journal, should be addressed to

ERNEST GREGORY, *Manager.*

26 Massachusetts Ave., Corner Boylston St., Boston, Massachusetts.

HARMONIZATION OF STATE AND FEDERAL NARCOTIC LAWS.

IN another column of this issue of the JOURNAL we publish a communication presenting questions about the operation of the new Harrison anti-narcotic law. These questions are excellent examples of the type of queries which must naturally arise in the minds of practitioners under the somewhat puzzling new conditions established by the enactment and enforcement of his law. They, therefore, deserve particularly careful and explicit reply, since the questions which have occurred to one will undoubtedly occur also simultaneously to many.

As we have very clearly stated in these pages, there are two narcotic laws which affect us at this time, the state law, which has been in effect since Jan. 1, 1915, and the federal law, which became active Mar. 1, 1915.

We also called our readers' attention to the fact that these two enactments do not harmonize, and directed particular attention to the provi-

sion in the state law governing compound pills, tablets and powders. These preparations may be dispensed and no record made of them, under the state law, if they do not contain more than 1/20 gr. of morphine or 1/4 gr. codeine, or any of their salts. Tablets containing heroin are not exempt, nor are suppositories.

The federal law does not exempt any of these preparations.

The state law does not exempt any drugs from record which are dispensed at the time of a personal visit. The federal law does this, but does not define the length of time covered by a personal visit. It may be reasonably interpreted to mean such medication as is needed to carry the patient along until the next visit of the physician, or for a period of 24 hours. It will be seen by this that the administration of morphine hypodermatically and the dispensing of morphine tablets in the case cited would comply with the federal law, if no record were made, but would violate the state law.

At a meeting of the Chamber of Commerce of the United States of America, on February 3, 1915, Mr. Charles Wesley Dunn presented an address advocating uniformity of state and national food and drug laws throughout this country; and on February 15 a special committee of the Chamber of Commerce reported a series of recommendations for legislation toward this end. Among these was recommended the enactment throughout the Union of a uniform state narcotic law "modeled after, and supplementing to the necessary degree, the recently enacted (Harrison) federal narcotic law, thereby to promote the effective, coöperative and harmonious regulation of the commerce in and the handling of narcotic drugs throughout the United States." A suggested draft for such a law was appended to the report, "with due appreciation of the fact that modifications may probably be necessary to meet local and other conditions."

In Massachusetts the movement has already been undertaken to establish such state legislation as shall accomplish this end and remove the present discrepancies and conflicts between the federal law and the previously existing state law. The bill proposed for this purpose (House No. 1814) has been reported in part as follows by the committee of public health:

"Section 1. It shall be unlawful for any person, firm or corporation to sell, furnish, give away or deliver coca leaves or any cocaine or any alpha or beta eucaine or any synthetic sub-

stitute for them, or any salts, compound or derivative thereof, except decocainized coca leaves and preparations thereof, or any opium, morphine, heroin, codeine or any preparation thereof, or any salt, compound or derivative of the same, except upon the written order of a manufacturer or jobber in drugs, wholesale druggist, registered pharmacist actively engaged in business as such, physician, veterinarian, dentist registered under the laws of the state in which he resides or an incorporated hospital, college or scientific institution through its superintendent or official in immediate charge, or upon the written prescription of a physician, dentist or veterinarian, registered under the laws of the state in which he resides, bearing the date when given, his office address, the registry number given him under public acts two hundred and twenty-three of the sixty-third congress, approved December seventeenth, nineteen hundred and fourteen, *the signature in full of the physician, dentist or veterinarian giving it, the name and address of the patient for whom prescribed, which prescription, when filled, shall show the date of filling and shall be retained on file by the druggist filling it for a period of at least two years. The prescription shall not again be filled, nor shall a copy of the same be made, except for the purpose of record by the druggist filling the same, and it shall at all times be open to inspection by the officers of the state department of health, the board of registration in pharmacy, the board of registration in medicine and the authorized agents of said departments and boards and by the police authorities and police officers of cities and towns.*"

The remainder of this section provides the exceptions applying to the prescription, sale or distribution of preparations not containing more than a stated minimal quantity of the given narcotic drug.

"Section 2. It shall be unlawful for any practitioner of veterinary medicine or surgery to prescribe any of the drugs mentioned in section one of this act for the use of a human being, and it shall be unlawful for any physician or dentist to prescribe, sell, give away or deliver any coca leaves or any cocaine or any alpha or beta eucaine or any compound, derivative or synthetic substitute for them, or opium, morphine, heroin, codeine or any preparation thereof, or any salt, compound or derivative of said substance to any person known to such physician or dentist to be an habitual user of those drugs.

"Section 3. The provisions of this act shall not be construed to prevent any lawfully authorized practitioner of medicine or of veterinary medicine or of dentistry from prescribing, administering or dispensing any drugs that may be indicated for any patient under his care."

The remainder of this section outlines the form and method in which the record book of drugs prescribed, dispensed or administered

shall be kept; and concludes with a provision that the "above record shall not be required where the physician or dentist administers, *outside of his office*, any of the drugs mentioned in this act, to a patient on whom he personally attends."

Sections 4 and 5 contain provisions relating to manufacturers or jobbers of drugs, wholesale druggists and registered pharmacists.

Sections 6 and 7 define the necessary licensure of persons coming within the provision of the act.

Section 8 provides for the exemption of common carriers engaged in transporting narcotic drugs, including nurses or assistants acting as the agents of physicians, dentists and veterinaries.

The remainder of the act is as follows:—

"Section 9. The provisions of this act, except those sections which require the ordering of the above enumerated drugs on an official order blank, and the keeping of the same on file, and the keeping of the record relative thereto, shall apply to cannabis indica and cannabis sativa, except the same shall not apply to prescriptions, preparations or remedies which do not contain more than one-half grain of extract of cannabis indica or more than one-half grain of extract of cannabis sativa in one fluid ounce, or if a solid or semi-solid preparation, to the avoirdupois ounce, nor to liniments, ointments or other preparations containing cannabis indica and cannabis sativa, which are prepared for external use only.

"Section 10. The repeal of any law by this act shall not affect any action, suit or prosecution pending at the time of the repeal for an offense committed or for the recovery of a penalty, or forfeiture incurred under any of the laws repealed.

"Section 11. Whoever violates any provision of this act shall be deemed guilty of a misdemeanor, and shall be punished by a fine of not more than one thousand dollars, or by imprisonment in the house of correction or jail for a term not exceeding one year, or by both such fine and imprisonment.

"Section 12. Chapter six hundred and ninety-four and chapter seven hundred and eighty-eight of the acts of the year nineteen hundred and fourteen and sections two to six, inclusive, of chapter three hundred and eighty-seven of the acts of the year nineteen hundred and ten are hereby repealed.

"Section 13. This act shall take effect upon the first day of April, nineteen hundred and fifteen."

Two points in this proposed law seem to deserve particular comment. In Section 1 it is provided that each prescription shall bear "the

signature in full of the physician, dentist or veterinarian giving it." Literally interpreted, this clause would mean the signing of the full Christian and middle name, if any, a procedure inconvenient and likely often not to be complied with. A clause should be added to the bill at this point defining the term, "signature in full," which, for the purposes of this act, is presumably equivalent to legal signature, that is, the habitual manner in which a name is signed.

The second point calling for comment is in the provision at the close of Section 3, which, as it stands, would require every physician or dentist to keep a complete record of any narcotic drugs administered to patients *in his office*. With the increasing use of local anesthesia for minor and even semi-major surgical operations performable in a surgeon's office, the inconvenience and impracticability of complying with this provision are obvious. There seems no valid reason why the same exemptions should not apply to drugs administered by a physician or dentist in his office, as to those administered by him to patients in their homes or at hospital. The clause, "*outside of his office*," should, therefore, we believe, be stricken from the prospective act.

In conclusion, we strongly urge the adoption of the personal visit exemption clause in the proposed state law which has been introduced in the House in an attempt to harmonize the state with the federal statute. Physicians who feel that this is desirable should regard it as their duty to the profession, as well as their personal interest, to express their opinion immediately to their representatives in the legislature.

FAMILIAL DISEASES.

In another column we publish a detailed report of a series of cases of progressive neuromuscular atrophy occurring in a family without heredity. The complex group of conditions, of which the cases described are examples, is attracting more and more attention as experience widens in these often exquisitely hereditary conditions. The cases reported by Dr. Hatch are of interest from the fact that although the disease described must be regarded as one of the hereditary type, it could not be discovered that it had appeared in previous generations. It must, of course, happen, and frequently has been

observed, that such diseases occur spontaneously in one generation, to be thereafter indefinitely transmitted; but what the conditions are which should suddenly cause this degenerative tendency remain, as yet, wholly obscure. It is not to be questioned that the intensive studies now being made on syphilis as a cause of race degeneracy must be considered in this connection, but as in all such problems, whatever its influence may prove to be, it can manifestly at present not be demonstrated why these particular forms of degeneration should occur. The future, no doubt, opens a wide field of speculation and possible investigation in this really practical field. In general it may be said that students of heredity may, with advantage, devote their energies to the investigation of such demonstrated family affections, rather than be led astray, as they too often are, into unfruitful fields. Apart from the interest which is connected with the family appearance of this group of disorders, a more satisfactory classification than we have at present is much to be desired, as, for example, a clearer line of demarcation, if such can be made, between the primary myopathies, the spinal atrophies and transitional forms, such as the cases reported by Dr. Hatch. We desire particularly to call attention to the original contribution of Dr. Hatch's article in the use of electrocardiograms to demonstrate graphically muscular tremors. It is altogether possible that the further use of this method may throw light upon the question of tremors in general and their possible diagnostic significance. A further contribution of importance is the systematic examination of the spinal fluid in such cases. Although these fluids were negative, so far as Wassermann reactions were concerned, they showed interesting alterations in the albumin and globulin content and a pathological gold chloride reaction. This also affords a valuable suggestion for future research. Such cases as these should be reported in detail in order that ultimately statistical material may be secured from which classifications of value may be made.

THE HARVARD EXPEDITIONARY UNIT.

ON Wednesday of this week, March 17, the Harvard unit sailed from Boston, aboard the

steamer *Canopic*, for Gibraltar, whence it will proceed for service at the American Ambulance Hospital in Neuilly, Paris. This unit will relieve that from the Western Reserve Medical School of Cleveland under charge of Dr. George W. Crile, which has served at the hospital since January 1. The Harvard unit will have control of 150 beds and will continue on service from April 1 to June 30. It will be in charge of Dr. Harvey Cushing as surgeon-in-chief and Dr. Robert B. Greenough as surgeon and executive officer. The further personnel of the unit will be made up as follows:—

“Richard P. Strong, M.D., professor of tropical medicine, bacteriologist; Robert B. Osgood, M.D., instructor in orthopedics, orthopedic surgeon; Beth Vincent, M.D., assistant in surgery, assistant surgeon; Walter M. Boothby, M.D., lecturer in anesthesia, anesthetist; Fred A. Collier, M.D., '12, Elliot C. Cutler, M.D., '13, Philip D. Wilson, M.D., '12, and Marius N. Smith-Peterson, M.D., '14, resident surgeons; Lyman G. Barton, Jr., M.D., '12, surgical assistant; Orville F. Rogers, Jr., M.D., '12, medical assistant; George Benet, M.D., '13, laboratory assistant; Miss Edith I. Cox, Miss Geraldine K. Martin, Miss Helen Parks and Miss Marion Wilson, operating nurses.”

The JOURNAL extends its most cordial good wishes for the safety and success of this Boston expedition, whose work will be not only of profit to its members, but of distinction and credit to the profession of this city and of New England. It is the expectation and hope of the JOURNAL to publish, for the interest and instruction of its readers, frequent communications from members of this expedition while it is at the front, and, after its return, more extended articles of medical research based on its experience.

COMPLIMENTARY DINNER TO DR. THEOBALD SMITH.

AFTER a service of more than twenty years to the Harvard Medical School, Dr. Theobald Smith is to sever his connection with the University, to assume larger duties in conjunction with the work of the Rockefeller Institute for Medical Research. The distinction of Dr. Smith's services to his college and to the advancement of medical science leads his colleagues to desire that some permanent memorial should be made on the occasion of his departure. The interest of Mr. Bela Pratt has been secured, and

it is proposed to present a bas-relief of Professor Smith to the Medical School. Reductions of this relief will be made and presented to contributors to the fund.

In addition to this permanent memorial, invitations have been issued to a complimentary subscription dinner to be given to Dr. Smith on Saturday evening, April 17, at the Harvard Club of Boston. The governors of the club have given the use of the large hall, and President Lowell is to preside. Already 150 acceptances have been received so that a large and successful gathering is assured. It is desired, however, that as many physicians as possible should take advantage of this opportunity to express the appreciation and realization of the profession of the importance and distinction of Dr. Smith's service to medical science and research, and their cordial good wishes and confidence in his promise of even greater achievement in the new duties to which he goes. The subscription (\$5.00) of all those wishing to take part in this occasion should be sent by March 20 to Dr. Marshal Fabyan, 379 Commonwealth Avenue, Boston.

MEDICAL NOTES.

BRITISH VITAL STATISTICS FOR 1914.—Statistics recently published in England show that during the year 1914 the crude death-rate of England and Wales was 13.9, the infant mortality 105 per thousand births, and the birth-rate 23.6. It is somewhat striking that the birth-rate is 25 in the larger cities, 24 in the smaller towns, and only 22 in the rural sections, whereas the corresponding infant mortality in these respective regions is 113, 104 and 93, respectively. The city of London, however, shows a higher birth-rate and a lower infant mortality than those of any of the other large British cities.

OVERCROWDING AND TUBERCULOSIS IN BRADFORD.—In a discussion before a recent meeting of the English National Anti-tuberculosis Association, Dr. Harold Varrow of Bradford, Yorkshire, called renewed attention to the much greater prevalence of tuberculosis among the overcrowded population of that city. In Bradford 106,000 live in houses having three rooms or less and 170,000 live in houses having four or more rooms. Nearly two-thirds of the pulmonary tuberculosis in the city occurs in the former group. Dr. Varrow pointed out that the eradication of tuberculosis is hardly to be expected until such overcrowding of urban population is controlled.

LOW DEATH-RATE IN NEW YORK.—The mortality in Greater New York for the past week was noteworthy by reason of the extreme low point reached by the death-rate, namely, 13.91 per 1000 of the population. This is an unprecedentedly low figure for this season of the year in this climate. The good showing of the figures of the past week, as compared with those of the corresponding week of 1914, is heightened by reason of the high mortality this time a year ago, due to exceedingly trying meteorological conditions and to the increase in the prevalence of influenza. A comparison of the two weeks will show that in the week of March 7, 1914 the deaths from influenza were almost treble, from diphtheria and croup and scarlet fever almost double, and from measles quadruple those of last week.

Viewed from the point of age, every age group showed a noticeably decreased mortality from the week of 1914. Under 5 years of age, the decrease was 118 deaths, between 5 and 65 years of age the decrease was 174 deaths, at 65 years of age and over, the decrease was 117 deaths.

These comparisons are made without allowing for any increase in population. If such allowance be made, the total decrease in the mortality of the past week with that of 1914 would be 486 deaths.

The death-rate for the first ten weeks was 3.90 per 1000 of the population, as against 15.41 for the corresponding period in 1914, a decrease of 1.51 of a point.

SANITATION IN PORTO RICO.—A recent report of the director of sanitation of Porto Rico, reprinted from the report of the governor of that island, records the activities of the department of public sanitation for the fiscal year ended June 30, 1914. During this period the total number of deaths in the island was 21,775, corresponding to a rate of 18.6 per thousand, as contrasted with a rate of 31.5 in 1888 and 40.8 in 1900. The report contains statistics of morbidity and mortality for the northern, eastern and southern districts of the island and an account of mosquito eradication in 50,574 premises on which a total of 55,567 breeding places were found and variously destroyed. The report also describes details of water supply, sewer system and municipal sanitation. The division of veterinary inspection reports forty-three positive cases of glanders. There are careful accounts of the prevalence and control of the various important infections on the island and a description of the work of the biological laboratory. The remainder of the report is occupied with statistical tables.

FOOT AND MOUTH DISEASE IN NEW YORK.—Report from Syracuse, N. Y., states that on March 8 a quarantine order was extended by the New York State Commissioner of Agriculture over Onondaga County because of the recent spread of foot and mouth disease in that region.

The situation is said to be particularly serious in the territory surrounding Syracuse, where 231 cattle have recently been killed.

AWARD OF THE GROSS PRIZE.—It is announced by the trustees that the Samuel D. Gross prize of the Philadelphia Academy of Surgery for the year 1915 has been awarded to Dr. John Lawrence Yates of Milwaukee, Wis., for his essay on "Surgery in the Treatment of Hodgkins' Disease." The amount of this prize is \$1500.

RABIES IN CALIFORNIA.—The California State Board of Health has recently published the results of an investigation which it has made in the prevalence of rabies in that state during the past five years. Since 1909 the disease has occurred in every section of the state except the northern coast and the mountain counties, and a few others where the population is very sparse. In 1912, 300 positive cases occurred in dogs, and in 1913, 320. During the last nine months of 1914 there was an abrupt decrease in the number of cases, which reached a total of only 100 in that year. During the quinquennium in question, there were 25 human deaths from the disease in California. It is interesting to note, and somewhat contrary to the usual conception, that, at least during the period under consideration, the disease was more prevalent in winter than in summer.

INFANTILE IMMUNIZATION AGAINST TUBERCULOSIS.—At a recent session of the British Royal Institute of Public Health in Edinburgh, Dr. Rist of Paris discussed the subject of bovine tuberculosis, to which he considers infants are peculiarly susceptible. At this meeting it was also suggested that early bovine infection, from which a child recovers, may, perhaps, serve the purpose of permanent immunization against infection with the human tubercle bacillus in later life.

EUROPEAN WAR NOTES.—Report from Serbia, by way of Berlin on March 11, states that typhus fever is extensively prevalent in Serbia. Nine American nurses have been infected, 63 physicians, including 2 Americans, have died of the disease, and the total number of deaths from it is said to reach several thousand.

It was announced on March 10 that the American Red Cross will soon send to Europe two additional units, of 3 surgeons and 12 nurses each, for service with the Belgian army in the field.

On March 11, the total of the New York Belgian relief fund amounted to \$969,851.24; the New York Red Cross fund to \$467,779.75; the American Ambulance Hospital fund to \$348,389.82; the American Jewish relief fund to \$532,937.14; and the New York Polish relief fund to \$25,225.47.

On March 13, the total of the New England Belgian relief fund amounted to \$233,127.57; the Massachusetts Red Cross fund to \$111,904.93; the Boston Jewish relief fund to \$44,274.42; the Polish relief fund to \$36,175.18; and the Lithuanian relief fund to \$12,303.95.

BOSTON AND NEW ENGLAND.

HOSPITAL BEQUESTS.—The will of the late Calvin W. Capen of Dedham, Mass., which was filed recently in the Norfolk Probate Court, leaves a residuary bequest, which it is estimated will amount to about \$100,000, to the Elizabeth F. Capen Hospital fund. This fund of \$40,000 had been already given by the testator to build a hospital in memory of his wife.

The will of the late William H. Storey of South Boston, Mass., which was filed on March 8 at the Suffolk County Probate office, contains a bequest of \$10,000 for the Boston Floating Hospital. The remainder of the estate is left in trust for the benefit of the testator's family, but after the death of certain beneficiaries, one-quarter of the income of the residue is to be paid to the Vincent Memorial Hospital of Boston.

EPIZOÖTIC OF FOOT AND MOUTH DISEASE.—On March 4 the quarantine in this state for foot and mouth disease was extended to include the town of Woburn, although no cases have, as yet, been discovered in that community.

On March 5 the quarantine was also extended to Melrose, Mass., and a number of infected or suspected cattle were killed in Lexington and Waltham, Mass. Two suspected human cases of the disease have been reported at Worcester, Mass., one of which is believed to be positive. No new cases among cattle have been reported since March 2, when 30 were found at North Grafton, Mass. At the same time additional powers have been given by the executive council to Dr. Lester H. Howard, commissioner of animal industry, to meet the situation arising from this recrudescence epizootic.

The order approved authorizes the commissioner to restrict at any time by order the movement of cattle, sheep, other ruminants and swine in any city or town of the Commonwealth, when, in his opinion, the control and eradication of foot and mouth disease require such action. He is empowered to extend or diminish the radius of quarantined areas surrounding premises on which foot and mouth disease exists or has existed since Nov. 5, 1914.

According to present indications, the total number of cattle destroyed by this second epizootic will approximate 900, as compared with 1156 in the first outbreak.

On March 9, nine new cases of foot and mouth disease were discovered at Marlboro, Mass., and on March 10, on account of the prevalence of the disease in Everett, the local quarantine was extended to the adjacent city of Chelsea.

CASES OF INFECTIOUS DISEASES reported to the Boston Board of Health for the week ending March 9, 1915: Diphtheria, 77, of which 7 were non-residents; scarlatina, 77, of which 7 were

non-residents; typhoid fever, 3; measles, 134, of which 2 were non-residents; tuberculosis, 73, of which 1 was non-resident. The death-rate of the reported deaths for the week was 18.17.

Obituary.
SAMUEL WOOD LANGMAID, M.D.

DR. SAMUEL WOOD LANGMAID died in Brookline, February 3, 1915, in his 78th year, closing a medical career which covered the period of half a century. He was born in Boston, June 26, 1837. His parents, Samuel H. and Dorcas Sawyer Langmaid, at the time of his birth were living on Charles Street; later they moved to Roxbury, and in 1855 to Cambridge. He was fitted for college at the Roxbury Latin School and was a member of the Harvard Class of 1859. A year after graduation from college he entered the Medical School, completing his course as surgical house officer at the Massachusetts General Hospital, and graduating in 1864, with the degrees of A.M. and M.D.

In June, 1864, Dr. Langmaid volunteered, and became acting assistant surgeon in the United States Army. He was at first ordered to White House Landing, Va., but the next month was sent to the hospital at Readville, Mass., where he served until the closing of the hospital a year later. After a few months in Europe he began general practice in Boston on Park Square. He was on the surgical staff of the Carney Hospital from 1868 to 1880. In 1866 the Children's Hospital was founded and he became one of the surgeons, serving until after the new building on Huntington Avenue was opened in 1882. He then gave up general surgery and established a department for diseases of the throat, of which he had charge for many years.

When Dr. Langmaid began practice the specialty of laryngology was slowly developing in Europe. On account of his own voice and his association with singers, he followed with interest everything connected with the larynx, and became one of the pioneers of the specialty in this country. He joined the American Laryngological Association in 1880, two years after its foundation, and was president in 1891, when the Association met in Boston. In 1881 he was appointed assistant physician for diseases of the throat in Dr. Knight's clinic at the Massachusetts General Hospital, and took charge of this clinic for six months in every year until 1892, when he resigned. He became a member of the American Climatological Association in 1887, and was vice-president in 1901. He was a member of the Massachusetts Medical Society, and of other medical societies and clubs in Boston.

Dr. Langmaid's private practice became more and more limited to the upper respiratory tract and after about 1880 he gradually withdrew

from other work. He had many patients among the musical and theatrical professions, and was often consulted by visiting singers and actors. He occasionally contributed to the literature of the larynx. He had three papers in the old *Archives of Laryngology*, which in 1880 started its short lived career. These papers were on "The Application of the Principles of Vocal Culture," "On the Singing Voice," and "A Common Form of Vocal Disability." He later published a dozen or more other articles, which are listed in the *Transactions of the American Laryngological Association* for 1898 and 1908. During the latter years of his life his health became poor, and he finally retired from practice in 1912.

Dr. Langmaid did much for vocal music in Boston. He had a beautiful tenor voice and he took every opportunity to promote good singing. While in college he sang in the college chapel, and was leader of the Glee Club. So irrepresible was his music that he was once summoned before the authorities for singing as he walked through the yard. In the course of his life he became a member of many musical associations, the Chickering Club, the Parker Club, the Boylston Club and later the Apollo Club and the Cecilia. Of his many interests, perhaps the one nearest to his heart outside of medicine was the Harvard Musical Association, of which he was president for many years. He was also a director of the New England Conservatory of Music. For a quarter of a century he sang tenor in the quartet at Trinity Church, before the establishment of the vested choir. He had a large acquaintance, not only among the musical people of Boston, but also among the noted singers of the world, several of whom were at times his patients.

His interests and his friendships were not confined to medical and musical circles. As a boy he spent his summer vacations in New Hampshire, and acquired a true sportsman's love for the woods, and for hunting and fishing. In later life, whenever he had the opportunity, he went off with his dogs into the country, or with his rod to some trout stream. He thoroughly enjoyed the life in the open, and the intelligence of his dog, and the fine art of fishing. But equally he sought the society of his fellow men and was a particularly sociable and congenial companion. He was a charter member of the Tavern Club and for some time a member of the Saint Botolph Club.

Dr. Langmaid married in 1870 Miss Ella M. Tuttle, and had two daughters, Miss Bertha Langmaid and Mrs. Conrad Hobbs. Mrs. Langmaid and both daughters survive him.

Miscellany.

MEDICAL EXTRACTS FROM SEVENTEENTH CENTURY LETTERS.

In a recent issue of the *Lancet* are published a number of extracts on medical topics from seventeenth century letters in the valuable manuscript collection of the Duke of Portland at Welbeck Abbey. Some of these are as follows:—

"*Richard Andrews to the Countess of Newcastle*, at Welbeck. London, May 10th, 1633.—"I understand your ladyship is with child, and that therefore you decide to be furnished with such help in physics as shall be fit, and such as you have had heretofore. I have therefore sent down to you a powder to hasten the birth and make it more easy. It is made of cassia, saffron, and borax. When you are in travail I would have you take of the powder as much as will lie upon a groat in a spoonful of burnt white wine, or bezoar water, or spirit of saffron. If you should be long in labour and grow faint, there is an excellent cinnamon water to take a small spoonful of to refresh your spirits. But there is a water in a little glass, called Adrian Gilbert's water, which is commended above all others in child-birth. There are other comfortable waters and spirits sent down in a little 'seller,' of which you may make use now or at any time. There is a glass of *confectio alehermes* to take a little of when you are fainting, and in the evening you may take the quantity of a dry bean, either alone or mingled with cordial water, and four or five grains of bezoar stone. I have also sent you an eagle stone which in time of labour being tied about the thigh will make the labour easier."

"*Matthæw Boucherett to the Earl of Newcastle*, Welbeck. April 23rd, 1637.—To enter into a discourse of the mineral waters lately found in Derbyshire, in Kedleston Park, though I could wish it had fallen into the hands of a more skillful inquisitor of nature, yet since your lordship commanded it from me I will deliver my opinion briefly. That I may treat of them in order, it is necessary to find out from what mineral they borrow their quality. That which we first meet with is their strong smell, which shows the waters pass through a matrix where bitumen or a kind of clammy clay, like pitch, being of the nature of brimstone, is generated. If anyone had rather determine that they pass through sulphurous veins, I am not he that will absolutely contradict him, yet I must tell him the country people affirm that silver being cast into that water, taken from the spring head, was presently died of a gold colour, and I cannot conceive how that should come from sulphur, but rather from the aforesaid bitumen joined with nitre or some other fossil salt, whose tenuity doth dye the silver of a gold colour. Moreover, that country is so replenished with mines of coal, which are nothing else but bitumen petrified,

that I may believe these waters pass through veins where coals are yet in their first principles, I mean before they be grown to a hardness, and from thence these waters borrow their quality. Besides some of these waters being distilled do show the same, for nothing whatsoever remains in the bottom of the lymbeck, but a little portion of salt with a certain black substance which clearly shows the smell, colour, and savour of bitumen. I cannot find any reason that they pass through veins of iron or vitriol. The taste denotes no such thing. I have mixed gall with them, which is accustomed to turn such waters to ink, but this hath not changed the colour of these. Out of these things it may be lawful to declare those waters to be bituminous and a little nitrous. From hence it is evident that they are of a hot temperament and abound with their spirits. Now, if it be safe to drink these waters they are good against ulcers in the neck of the bladder. If they be actually hot, they are good against all old pains in the joints arising from moist and cold causes, being used in manner of a bath. As they are, they are good to exsiccate all external ulcers."

The freedom of speech in the former of these letters reminds one of the French lady in Sterne's *Sentimental Journey*. Another group of letters deals with the smallpox and its treatment:—

"*Samuel Wildey to the King*.—1660, October 8, Rotterdam—The general report being here that his Highness the Duke of York is by God's Almighty hand visited with the small pox, I most humbly pray your Majesty that a drop of blood should not be drawn from the veins of his Royall Highness, being very dangerous in his condition and firstly cause the death. The long experience that I have in that sorte of sickness make me so bold to sent my advice to your Majesty."

"*The Same to the Same*.—(No date.)—Remedy for the small pox: Take new laid eggs, three yolkes and whites, fry them in fresh butter that was never salted, twelve ounces, till the eggs be very hard. Then pour the butter from the eggs into a basson full of fayre cold water. Let it stand till the butter be cold and eaked, then take it off from the water and put it into a fayre vessel and beat it with a wooden spatter, continually adding three or four drops of damaske rose water, till the butter with beating come to be white. Then take of that unguent four ounces, add to it *saccarum* sugar-candy, *albi* two drams, finely pulverizated misse, *fyat electuarium*. Be sure to give of this three times a day, and so in the night the quantity of a nutmegg upon a knife point. Let it dissolve in his mouth and swallow it down—this by God's grace and assistance will cure the small pox in the throat which is the cause of most men's death in that disease. Then take the unguent without the candy and warme it in a saucer and anoynt the face and eyes with a feather morning and evening, and this preserves the eyes and keeps the face from

pitting. . . *Probatum est*. Now if it please God that his Royall Highness the Duc of York cannot sleep, lett a live pidgeon be slitt in two, and one halfe be applyed so soone as it is splitt to the sole of one foot and the other halfe to the sole of the other foot, fast bound with rowlers and so remaine twenty-four houres, and by God help that will procure sleep and extract the venemous quality of the disease from the heart and vitall spirits."

Still another group deals with cancer of the breast:—

"*Margaret Lady FitzJames to her Sister, Lady Harley*.—1673, Aug. 1, Fairfield.—My sister is now in ease, and as cheerful as it can be expected. The wound in her breast is narrower than it was but very deep, to the very bone. The doctor fears it is incurable. She has been for four days before I came in extreme pain which was caused by Sir John Wroth's tricks, exciting his horse into a fury. . . The doctor says my sister may live some years, but if the humor should come to be sharpe, as it was once before, I fear her time will not be long. The doctor speaks of ten years."

"*Ann Palmer to her Sister, Lady Harley*.—1673, Aug. 2.—I have a great deall to say if I were with you but can't in a letter. My breast is broke as I beleve you have heard, and it eats away more and more, soe as the doctor tells me plainly that there is noe cure but by manuall operation, and that is soe dangerous and painfull as I thinck not to submit to it, for he saith the cancer is fixt, and, as he thinckes, the rib is fouled. Though it was the first as I heard speak of it yet to mee it was not straining, because I thought it was soe afore. There are waters in this country which have cured a cancer in a woman's breast but it is not like mine; but being now in a desperate condition I am willing to try it as it is approved by the doctor to allay pain and keep the melancholy humor low. I was for a fortnight in great pain but now I am at ease."

THE FUNCTION OF THE CORPUS STRIATUM.

THE knowledge of the function of the corpus striatum in the human brain has long been involved in considerable obscurity, since electric stimulation of this region fails to elicit definite motor response. Evidence of degeneration in the lenticular portion of this basal mass of grey matter may however be clinically evidenced by a syndrome of symptoms characterized by motor disturbance, spasm and tremor. In the issue of the *Lancet* for April 27, 1912 (p. 1115), Dr. S. A. K. Wilson described this lenticular syndrome at length. In a recent number of *Brain* (vol. xxxvi, p. 427), Dr. Wilson further recorded the results of experimental lesions of the corpus striatum and their significance. This latest re-

search has been editorially reviewed in the *Lancet* in part as follows:—

"Electrical stimulation of the lenticular nucleus failed to induce any motor effect, thus confirming the results of most other observers. Electrolytic destruction, however, of definite portions of this nucleus was carried out on monkeys, which, after a period of three weeks, were destroyed, and the degenerated areas carefully examined. The results showed, in the first place, that the corpus striatum is independent of the cerebral cortex; it is also not connected directly with the spinal cord. Connections are more intimate, however, with the optic thalamus and regio subthalamica, including the red nucleus, and this fibre system links especially with the globus pallidus portion of the corpus striatum. It is clear that this body is an autonomous centre. Its function is exercised independently of the cerebral cortex but is motor in type, and is exercised in an efferent or caudal direction. Developmentally, it appears that in the lower forms of vertebrate life the corpus striatum exercises a more dominant motor control than it can exert in the higher forms, although such control cannot attain the complexity and range afforded by the elaboration at a later phase of the cortical brain or neopallium. The final function of the corpus striatum appears to be something of a 'steading' influence upon pyramidal innervation exerted through the strio-rubro-spinal tract. How this effect is brought about is suggested to be by virtue of what Sherrington terms the 'final common path.' The idea conveyed by this definition is that an end neuron effect, of motor type for instance, depends for its manner of action upon the particular stimulus applied to its arborisations at its proximal end, which stimulus, however, may be of varying nature, and may also reach the end neuron along different converging channels. The type of final stimulus is itself determined by the coördinate relationships between the possible sources. Amongst such channels are recognized cortical and cerebellar influences, for example: in addition, the corpus striatum is claimed to be capable of exerting an effect. Clinically it is suggested that absence of striate control induces tremor, well exemplified in cases of progressive lenticular degeneration. One question remains to be answered: Why is it that in the experiments performed tremor did not result? The reason suggested is that possibly the wide variation in functional capacity of the lenticular nucleus in different species, a variation worthy, apparently, of particular comment, forbids the anticipation that results gained in experiments upon the ape need necessarily be identically reproduced in man."

It may be that, situated as it is in intimate relation to the internal capsule, the corpus striatum when undergoing degenerative processes would affect the function of the motor fibres in the capsule. Such processes would be likely to arise from arterial disease of the twigs from the

anterior choroid artery supplying this region. Apparently the demonstrated functional activities of the corpus striatum are resident rather in its lenticular than in its caudate portion.

INVESTIGATION OF POLIOMYELITIS IN VERMONT.

IN the issue of the JOURNAL for Dec. 24, 1914, we noted the arrangements for a comprehensive study of poliomyelitis in Vermont by the State Board of Health in coöperation with Dr. Simon Flexner of New York and Dr. Robert W. Lovett of Boston. The following letter to the daily press from Dr. Charles S. Caverly, president of the Vermont Board of Health, states interestingly the progress and plans of this valuable piece of research:—

"In common with most of the Northern states, Vermont has suffered quite severely at times during the last 20 years from this disease. The first notable outbreak of the disease recorded in literature occurred in this state.

"We have during the last five years had two rather sharp outbreaks, and each outbreak of course leaves the usual number of cripples. It has become a very serious problem, and the medical profession throughout the country has been taking a very live interest in solving the problems presented by this disease. As is well known, these problems have received much attention at the Rockefeller Institute in New York, and at various other points, especially Boston, where Dr. Lovett himself has been prominently identified with the work.

"The state board of health of Vermont has recently been given a considerable sum of money by a loyal Vermonter, who has been observant of the disastrous effects of these epidemics of infantile paralysis. With this money, the board has undertaken three lines of work.

"First, it has been able to interest and secure the coöperation of Dr. Robert W. Lovett, of Boston, who has been to five points in the state to examine and recommend treatment for those who have been maimed by the disease. It would be difficult to overestimate the success so far of Dr. Lovett's work. He has succeeded in interesting physicians, nurses and parents, so that everywhere his suggestions, seconded by those of his assistant, Miss Wright, are being most carefully and persistently followed out. The detail of the work undertaken by the board seeks to minimize the effects of the disease.

"The second line of work undertaken by the board in this connection has been research work into the cause and methods of transmission of the disease. The board has been exceedingly fortunate in securing the help of Dr. Simon Flexner of the Rockefeller Institute in the work, and he has detailed Dr. H. L. Amoss, his assistant, to conduct the work in Vermont. The board

has fitted up a laboratory in the College of Medicine at Burlington, which was placed at its disposal by the university authorities. With the aid of animal experimentation, it is hoped to throw some light upon the baffling problems presented by the epidemiology of this disease. Dr. B. H. Stone, the director of the laboratory, will have charge of this work in Dr. Amoss's absence from Vermont, and Dr. Towne, a young graduate, has been engaged to devote all his time to the details of the laboratory work.

"In the early summer it is planned to have meetings at various places in the state, to which physicians will be invited to listen to the best authorities available on the subject of the cause and prevention of infantile paralysis. This is the third detail of the campaign we are conducting.

"There were approximately 275 recognized cases of this disease in Vermont during the last summer. Fifteen per cent. of these were fatal. The disease has been at times quite prevalent throughout the Northern states, and it is not known that Vermont has suffered more than her neighbors.

"We have been keeping very close track of the cases and made a detailed study of the disease, as it has occurred in our state. The most careful preventive measures are being everywhere adopted, as it presents itself.

"CHARLES S. CAVERLY.

"President of the State Board of Health
"Rutland, Vt., Feb. 24."

MEMORIAL OF DR. HENRY CUTLER BALDWIN.

The following memorial notice of the late Dr. Henry Cutler Baldwin recently appeared in a Boston daily paper:—

"Those who have been privileged to receive the ministrations of Dr. Henry Cutler Baldwin feel that in his death they have suffered an irreparable loss. He was a wonderful physician; he had an insight that gave him, as it were, a power of divination; he brought to all his immense knowledge and skill, to his observation and experience, an imagination that penetrated to the hidden all, controlled by a vigorous judgment. Some of the cures that he wrought were like miracles. His earnestness, his determination, his interest, his will, that sometimes seemed as if it would dominate fate, were all factors in his success. Those who have seen him bring the all but dead to useful life, make the dumb speak, find the concealed malignity that no one else suspected, build up sick nerves, control the insane, keep mania in check, could only feel that he was incarnate wisdom. But his personal characteristics were as valuable as his medical knowledge and skill. His gentleness, his willingness, his benignity, his courage, his power of in-

spiring confidence, were like an atmosphere. When he came in he brought sunshine with him, and care and apprehension vanished.

"From his youth he was of stainless purity and lofty ideals. In moments of relaxation there was a charming boyishness about him that was very engaging; he had a fine and delicate sense of humor; he enjoyed poetry and a good book; he was exceedingly fond of music, having a rich and pure tenor voice, and being one of the leading singers of the Cecilia Society. He had been round the world with a patient in the early years of his practice, and had visited Europe and the Pacific Coast many times afterwards. He had seen the best of art in Europe and Asia and the islands of the seas, and was really a connoisseur, although without pretensions. He was very fond of animals, devoted to his dogs, and a daring horseman.

"His home life was very beautiful, full of gentle courtesies and sweet appreciations, full of recognition of the cheer and comfort and sympathy he received. And for the rest, his charity was unbounded. There should be a host of grateful patients from whom he refused to take a penny to rise up and call him blessed. He died, at far too early an age, a victim to his absorption in his work for his fellow men, a martyr to his profession.

"HARRIET PRESCOTT SPOFFORD.

"March 5, 1915."

Correspondence

AN OLDEN-TIME NUTRITION LABORATORY.

Boston, March 5, 1915.

Mr. Editor: The following is from the *Spectator*, contributed by Addison, and well describes the "Mallade Imaginaire" of Molière.

"The following Letter will explain it self, and needs no Apology.

"Sir,

I am one of that sickly Tribe who are commonly known by the name of *Valetudinarians*; and do confess to you that I first contracted this ill Habit of Body, or rather of Mind, by the Study of Physick. I no sooner began to peruse Books of this Nature, but I found my Pulse was irregular, and scarce ever read the Account of any Disease that I did not fancy my self afflicted with. Doctor *Sydenham's* learned Treatise of Fevers threw me into a lingering Hectick, which hung upon me all the while I was reading that excellent Piece. I then applied my self to the Study of several Authors, who have written upon Phthisical Distempers, and by that means fell into a Consumption; till at length, growing very fat, I was in a manner shamed out of that Imagination. Not long after this I found in my self all the Symptoms of the Gout, except Pain; but was cured of it by a Treatise upon the Gravel, written by a very ingenious Author, who (as it is usual for Physicians to convert one Distemper into another) eased me of the Gout by giving me the Stone. I at length studied my self into a Complication of Distempers; but, accidentally taking into my Hand that Ingenious Discourse written by *Sanctorius*, I was resolved to direct my self by a

cheme of Rules, which I had collected from his Observations. The Learned World are very well acquainted with that Gentleman's Invention; who, for the better carrying on of his Experiments, contrived certain Mathematical Chair, which was so Artificially hung upon Springs, that it would weight any thing as well as a Pair of Scales. By this means he discovered how many Ounces of his Food pass'd by perspiration, what quantity of it was turned into nourishment, and how much went away by the other channels and Distributions of Nature.

"Having provided my self with this Chair, I used to Study, Eat, Drink, and Sleep in it; insomuch that it may be said, for these three last Years, to have lived in a Pair of Scales. I compute myself, when I am in full Health, to be precisely Two hundred Weight, falling short of it about a Pound after a Day's Fast, and exceeding it as much after a very full Meal; so that it is my continual Employment to trim the Ballance between these two Volatile Pounds to my Constitution. In my ordinary Meals I fetch myself up to Two hundred Weight and a half Pound; and if after having dined I find my self fall short of it, I drink just so much Small Beer, or eat such a quantity of Bread, as is sufficient to make me weight. In my greatest Excesses I do not transgress more than the other half Pound; which, for my Health's sake, I do the first Monday in every Month. As soon as I find my self duly poised after Dinner, I walk till I have perspired five Ounces and four Scruples; and when I discover, by my Chair, that I am so far reduced, I fall to my Books, and study away three ounces more. As for the remaining Parts of the Pound, I keep no account of them. I do not dine and sup by the Clock, but by my Chair; for when that informs me my Pound of Food is exhausted I conclude myself to be hungry, and lay in another with all diligence. In my Days of Abstinence I love a Pound and an half, and on solemn Fasts am two Pound lighter than on other Days in the year.

"I allow my self, one Night with another, a Quarter of a Pound of Sleep within a few Grains more or less; and if upon my rising I find that I have not consumed my whole quantity, I take out the rest in my Chair. Upon an exact Calculation of what I expended and received the last Year, which I always register in a Book, I find the Medium to be Two hundred Weight, so that I cannot discover that I am impaired one Ounce in my Health during a whole twelve-month. And yet, Sir, notwithstanding this my great Care to ballast my self equally every Day, and to keep my Body in its proper Poise, so it is that I find myself in a sick and languishing Condition. My Complexion is grown very sallow, my Pulse low, and my Body Hydropical. Let me therefore beg you, Sir, to consider me as your Patient, and to give me more certain Rules to walk by than those I have already observed, and you will very much oblige

"Your Humble Servant!"

Possibly the unfortunate plight of the gentleman so graphically described by Addison has a lesson for modern times, so that, when calculating calories for our patients, we must not lose sight of the *psychic* element and its influence on metabolism.

Yours truly,

WM. PEARCE COYES, M.D.

QUESTIONS ABOUT THE HARRISON LAW.

CAMPELLO, MASS., March 4, 1915.

Mr. Editor: I have noted your several explanations of the Harrison Bill. There are still at least two points not clear to me, viz.: If a physician "personally attends" a patient with severe "gall-stone colic" and administers a dose of morphia hypodermatically and feels the patient may need more morphia before morning or before he can again visit him, would the contingent dose or doses be included under the phrase "personally attends"?

Again, many of us have long been in the practice of personally dispensing compound cough tablets containing codein heroin, etc. The Harrison bill does not mention such contingency. Will you kindly enlighten me as to what are my privileges in such cases and greatly oblige,

Yours very truly,

J. H. AVERILL, M.D.

[NOTE.—We have answered these questions in the leading editorial of this issue of the JOURNAL.—ED.]

BELGIAN PHYSICIANS' RELIEF FUND.

REPORT OF THE TREASURER OF THE COMMITTEE OF AMERICAN PHYSICIANS FOR THE AID OF THE BELGIAN PROFESSION FOR THE WEEK ENDING MARCH 6, 1915.

Deficit\$3.10

F. F. SIMPSON, M.D., Treasurer,
7048 Jenkins Arcade Bldg.,
Pittsburg, Pa.

All interested in the welfare of those remaining in desolated Belgium have felt serious concern on account of the more recent diplomatic notes issued by the belligerent countries and the disquieting inferences drawn from them. From about the first of December until the present time, all the warring nations have given the American Commission for Relief in Belgium the sole right to carry supplies for civilian citizens into Belgium and have strictly respected the flag of the Commission both at sea and on land. Such assurances still exist but the restrictions rendered necessary by the urgent requirements of drastic war measures greatly increase the difficulties of transporting supplies to Rotterdam and thence to the ultimate ramifications in Belgium.

The practical significance of all this is:

First. The English government has withdrawn its monthly contribution of seven million dollars for the relief of civilian Belgians.

Second. The difficulties of transporting food from England to Rotterdam may be expected materially to reduce the shipment of supplies from individuals and charitable organizations in England to Belgium.

Third. The need for redoubled efforts on the part of Americans is correspondingly more urgent.

The following communications which appeared in the *New York Times* and other papers throughout the country March 3 and 4 are interesting and significant:

"London, March 2.—Walter Hines Page, the American Ambassador, today addressed a letter to Herbert C. Hoover, chairman of the American Commission for Relief in Belgium, explaining the diplomatic conditions under which the Commission must work.

"First. All foodstuffs must be the absolute property of the Commission for Relief in Belgium.

"Second. Foodstuffs must become the property of the Commission at the port of departure. In no other way can safety of delivery to Belgium be secured.

"Third. Foodstuffs must be transported in ships under the control of the Commission because these are the only ships whose safety the belligerent governments guarantee.

"Fourth. The distribution in Belgium must be carried out absolutely under the control of the Commission, because supplies cannot reach the people through any other channel and because the governmental guarantees hold only with reference to food belonging to the Commission."

"New York, March 3.—Mr. Linden W. Bates, Vice-Chairman of the Commission for Relief in Belgium, who is the directing head of the Commission's work in this country, at his office, 71 Broadway, was asked yesterday if he had any comment to make on the latest move with reference to the transportation end of the Commission's work. Mr. Bates made this statement:

"In connection with the reports that relief work in Belgium may be hampered by the channel and North Sea situation, it can only be said that the work for relief must go on, and we expect surely to continue to get food into Belgium. In response to inquiries made today from the State of Kentucky and elsewhere as to whether the Commission would continue to receive or buy food, I answered that it would."

The American Commission for relief in Belgium is undertaking to deliver the supplies we furnish without cost to our Committee.

Of course, it is conceivable that some of the vessels carrying supplies for the American Commission for Relief in Belgium might strike mines or might otherwise be interfered with, but that in no wise diminishes the urgent need for persistent effort to supply the necessities of life for the destitute civilians of Belgium. The greater difficulties confronting us must be met with renewed energy and increased effort.

SOCIETY NOTICE.

NEW ENGLAND PEDIATRIC SOCIETY.—The thirty-seventh meeting of the New England Pediatric Society will be held in the Boston Medical Library, Friday, March 26, 1915, at 8.15 P.M.

The following papers will be read:

1. "The Management of Breast Feeding with Case Reports," Dr. C. K. Johnson, Burlington, Vt.
2. "Air and Water as Curative Agents," Dr. Roland G. Freeman, New York City.

Light refreshments will be served after the meeting.

E. M. BUCKINGHAM, M.D., *Pres.*
RICHARD M. SMITH, M.D., *Sec.*

APPOINTMENT.

Dr. Edward W. Barrett of Medford, Mass., has been appointed city physician of that community. He is a member of the American Medical Association, The Massachusetts Medical Society and the Medford Medical Society.

RECENT DEATHS.

DR. JOHN P. DENNETT, who died of heart disease on March 3 at Arlington, Mass., was born in Barnstead, N. H., in 1840. After studying dentistry at the Baltimore Medical College, he settled in the practise of his profession at Gloucester, Mass., from 1867 to 1887. In 1888 he removed to Boston where he continued in practise until his retirement in 1903. He is survived by his widow and by three daughters.

DR. ALBERT SIMON NEWCOMB, who died of heart disease recently at Schenectady, N. Y., obtained the degree of M.D. from the Albany Medical College in 1866. During the Civil War he served for a time as surgeon of the 24th New York Regiment and was subsequently medical examiner for various life insurance companies. He retired in 1903. He is survived by his widow.

DR. THOMAS HENRY MAGUIRE, who died of pneumonia on March 4 at Dorchester, Mass., was born in South Boston in 1878. After graduating from the Boston Latin School he studied medicine at the Harvard Medical School from which he received the degree of M.D. in 1900. After serving as a house officer at the Carney Hospital he settled in the practise of his profession at Dorchester. He was a member of the American Medical Association, The Massachusetts Medical Society, the Harvard Medical and Carney Hospital Alumni Associations. He is survived by his widow and by one daughter.

DR. OMAR ALPHA FLINT, a retired Fellow of The Massachusetts Medical Society, died at his home in Dracut Center, February 16, aged 71 years. He was a graduate of the University of Vermont College of Medicine in 1885. He was at one time superintendent of the Westford Reformatory and also superintendent of schools at Billerica.

DR. ALFRED MASON AMADON, formerly of Boston, died at Saranac Lake, N. Y., March 6, aged 48 years. Dr. Amadon was a graduate of the Dartmouth Medical School in 1897 and became a Fellow of The Massachusetts Medical Society in the same year. He had been in poor health for several years.

THE RÔLE OF THE STATE SANATORIUM IN THE TUBERCULOSIS PROBLEM.*

BY ELLIOTT WASHBURN, M.D., RUTLAND, MASS.,

*Superintendent, Rutland State Sanatorium,
Rutland, Mass.*

IN Massachusetts, as elsewhere, the tuberculosis problem is the care, relief and cure, if possible, of those afflicted with the disease and the prevention of its spread to those not so afflicted.

In our attempts to solve the problem we have several existing agencies, which may be classified as State, Municipal and Private.

Of private agencies we have anti-tuberculosis societies and various philanthropic organizations which maintain tuberculosis camps, dispensaries and clinics, tuberculosis nurses, visiting nurses and social service workers.

Municipal agencies comprise local boards of health, municipal hospitals and dispensaries for the care of the tubercular, visiting nurses, and medical inspectors of school children.

The agencies maintained by the State include the Trustees of Hospitals for Consumptives, the State Department of Health, State Inspectors of Health, Industrial Health Inspectors, four State Sanatoria for the tubercular, the tuberculosis wards of the State Infirmary at Tewksbury, the Prison Hospital for the reception of male tuber-

* Read before the Medical Association of Northern Berkshire, at North Adams, Mass.

cular prisoners, the tuberculosis wards of the various state hospitals for the insane, and the follow-up nurse of the Trustees of Hospitals for Consumptives.

In this problem what is the rôle of the state sanatorium? How is it performing this rôle? Do the results obtained justify the expenditure of the large sums of money necessary for its maintenance and continuance?

The first state sanatorium in Massachusetts, and for that matter in the United States, was established at Rutland and opened its doors October 1, 1898. The original intent of those through whose wisdom and influence the sanatorium was made possible, was to provide a place in which early and favorable cases of pulmonary tuberculosis might, in the first instance, be restored to health and earning capacity, and, in the second instance, might become so educated at the sanatorium in the steps and precautions necessary to prevent the spread of the disease that upon returning to their homes they might act as disciples or apostles to carry the doctrine of prevention broadcast throughout the state or wherever they chanced to go.

As time went on it was found that this initial scope of the sanatorium was too narrow; that while it provided for the care of the early and favorable case it made no allowance for the care of that case which was advanced to the stage where hope of its arrest was either much lessened or was wholly lost, and which was often far more dangerous to the health of the community in which it existed than was the early case. Thus it became necessary in the absence of local facilities for the hospital care of such cases for

the state to establish and maintain other sanatoria in which cases of the disease in all its stages might be received. So that to the original two functions of the state sanatorium was added this third, the care of the advanced case, not so much with the thought of getting him well as of removing from his home and community an active focus of the spread of the disease. Rutland was still reserved, and today is still reserved, as much as possible for the reception of the early cases.

Time next demonstrated that while it was possible for the sanatorium to carry out in a satisfactory manner the first two of its functions it was not always possible to do so in the case of this third function—the care of the advanced case—because in many instances these advanced cases, placed in the state sanatoria far removed from their homes, refused to remain there and insisted upon returning to their homes. This was the not unnatural instinct of persons very ill and weekly growing worse, to be at home with their families and friends. To this fact, perhaps more than to any other, is due the establishment of local or municipal hospitals for the care of this disease, which is now mandatory upon cities in this Commonwealth and upon towns when so requested by the State Department of Health. The supreme hope is that eventually enough of these municipal hospitals will be established to care for most of the advanced cases which need hospital care and have established a legal settlement in their respective cities and towns. This would leave the state sanatoria for the care of the early cases and for such advanced cases as are “State cases” so called,—that is to say, those who have no municipal settlement, which would to a large extent do away with the present long waiting list of applicants for admission to all of the state sanatoria. Early cases are, as a rule, contented to remain in a state sanatorium, even if at some distance from home, so long as they continue to show improvement.

We find, therefore, that the rôle of the state sanatorium is of a three-fold nature,—the care and arrest of favorable cases, the education of its patients to the end that they may disseminate their knowledge of the methods necessary to prevent the spread of the disease, and the care of advanced cases, which makes possible their removal as foci of disease in their homes and communities.

How are the several functions of its rôle being performed?

In the sanatorium the care and arrest of favorable cases stands upon a tripod, of which one leg is rest, one leg is fresh air, and the third is a combination of a regulated diet and supervised exercise and work. To my mind the relative importance of the pedal extremities of this tripod is in this same order. Drug medicines play an extremely minor part in the “treatment” and unless used in connection with these three principal methods of attack ordinarily will ut-

terly fail. Nor does the physician in private practice who prescribes medicine for his tuberculous patient, and stops there, fulfill his entire obligation to his patient.

Again, the sanatorium finds that rest, air and regulated life are not in themselves sufficient to restore favorable-stage patients to health and working capacity. The co-operation of the patient himself is a highly important factor; without it the “treatment” is not given a fair chance. Thus there enters the question of the personal equation of every patient, his temperament, his mental make-up, his willingness to carry out his instructions and the sanatorium rules in regard to the details of the treatment. So that we find today in our state sanatoria that we have to deal with two very distinct classes of patients and we so classify them, the “Sanatorium or Co-operating or I’ll try” class and the “Hospital or Non-co-operating or I don’t much care,” class. Already it has been demonstrated that more recoveries and more improved cases occur in patients of the “Sanatorium” class than in patients of the “Hospital” class. Those of the first class carry out the treatment as it is outlined for them to the best of their ability. Those of the second class either are careless and indifferent in their attitude or else are openly defiant to the rules laid down for the improvement of their physical welfare. The records show that those of the second class pay physically a heavy penalty for their indifference, neglect or willfulness.

More and more it is coming to be recognized that the sanatorium has not performed its whole duty to its favorable cases when it has merely restored them to health. They need something else which is quite essential and indeed vital to their future and that is their restoration to working, earning capacity. There is grave danger that prolonged residence in the sanatorium may, as Dr. Herman Biggs has so well said, “convert working invalids into fairly healthy loafers.” Many enter the sanatorium who work almost up to the day of admission. The inherent danger exists that some may leave the sanatorium, restored to health, it is true, but by their long stay in the sanatorium rendered so “soft” so “out of training” for the task of earning their own living and, in some instances I fear, so saturated with the fixed idea that the State must take care of them, that they return to their communities unfit, physically and temperamentally, to work at supporting wages until after considerable periods of time have elapsed. I would by no means give the impression that this is true of all cases; far from it; but in some instances it does occur. In what way does the sanatorium seek to avoid this unfortunate phase? By a system of graduated and supervised work while in the sanatorium. Work is a necessary and important part of the treatment, graduated and carefully supervised work, commencing with a half hour daily and working slowly up to six or seven hours daily work of such

kind as the sanatorium is able to provide. And in this last clause we find a weak spot in our treatment and a hindrance to the effective carrying out of our plan, for the sanatorium is able to provide only a limited amount of work and of very limited kinds.

The ideal carrying out of the plan would provide for every patient work similar to that to which his ante-sanatorium life has accustomed him. This is obviously out of the question in the sanatorium and all that we can provide is light work about the wards and grounds with an occasional job at carpentering for the men and sewing for the women. We need workshops in which light manual labor of a productive kind may be carried on under the watchful supervision of an officer paid for that sole purpose.

Such graduated, supervised work not only serves to occupy the patients' minds, to relieve the tedium of their sanatorium life and to keep them contented and out of mischief, but it serves the more important purpose of putting them in such physical condition that upon leaving the sanatorium they can at once enter upon a productive and self supporting life. So I say that such work is a very essential part of the treatment.

Occasionally we find the patient who flatly states that he does not propose to do any work unless he is paid for it; that he does not intend to work for the State for nothing. For such ingrates the Trustees have provided a remedy—dismissal. The law forbids our paying for such work, although in some sanatoria in other states, notably at Otisville, New York, the plan of paying patients for work has been found to work very well inasmuch as patients are thus enabled to send money home to their families and are themselves enabled to stay longer at the sanatorium than they otherwise would be able to stay.

At Rutland, ever since its opening, the custom has prevailed of taking suitable persons on as paid workers upon their discharge as patients. Through this custom many have been enabled to live and support themselves who might otherwise have been obliged to return to unsuitable, or unhealthy, conditions of climate, home surroundings or occupations, and who in all likelihood would under such conditions have broken down or become permanent dependents or have died. This custom, although it possesses certain advantages to the ex-patients as outlined, has also certain disadvantages as far as the economy and efficiency of sanatorium administration are concerned, into which we will not go. At the present time approximately fifty per cent. of all employees upon the Rutland pay-roll were at one time or another patients in the sanatorium.

The second function in the rôle of the state sanatorium is the education of its patients, its nurses, physicians and other employees. As far as the patients are concerned this education is imparted by talks to groups of patients or by individual conferences with individual patients

but to a much greater extent by their constant observation of the methods employed at the sanatorium in the prevention of the spread of the disease from the sick to the well. Even patients of the "Hospital" class unconsciously assimilate considerable education in this manner while the majority of all patients are eager to learn not only how they themselves contracted the disease but also how they may when they leave the sanatorium instruct others in its prevention.

This educative function of the sanatorium should properly include the instruction of the medical profession. There is in our state sanatoria a magnificently neglected opportunity for physicians to perfect themselves in the diagnosis and care of pulmonary tuberculosis. An abundance of clinical material, well equipped laboratory facilities, a hearty invitation to physicians and a cordial welcome on the part of our medical staffs have not served, save in rare instances, to overcome their reluctance to travel a few miles out of the beaten paths or the instinctive dislike of things tubercular which extends even to the medical profession itself. This opportunity is freely offered to the medical profession. It is seldom improved.

The third function, the care of advanced cases, is fulfilled by the provision of proper medical care for such cases and by making their last months and days as comfortable as possible. These are the open, active cases, many of them alternately ambulatory and bed cases for long periods of time, which are dangerous to the health of their homes and communities unless they can be cared for in a state sanatorium, a municipal tuberculosis hospital, or in their own homes under proper and competent guidance which is often impossible and oftener impracticable.

In the performance of this function the sanatorium is handicapped by the fact already mentioned of the difficulty in keeping advanced cases in a state sanatorium, far from their homes, when they find that they are gliding down hill physically. This desire to return home plus the fact that many cities and towns have no adequate facilities for the reception and care of such cases results in the return of these patients to their homes where in many instances the care afforded to the patient and the protection rendered to his family are neither adequate nor satisfactory. Thus in a measure this function of the sanatorium is defeated and the State has wasted time and money on such patients to the detriment of more favorable cases who have been kept out of the sanatorium because the beds were filled.

Still again we have to deal with that class of dangerous consumptives who have been styled the "incorrigible," the "unteachable" the "wilfully careless" consumptives. These often appear to care for no one but themselves and sometimes not even for themselves. These are they who through ignorance, wilfulness or just sheer "cussedness" neglect or refuse to take any

necessary precaution, who wilfully and flagrantly violate the spirit and the letter of all sanatorium laws and rules and of similar laws in their own communities and homes, who through the abuse of alcohol or otherwise, even in the sanatorium, deliberately offset any physical good that the sanatorium can possibly offer to them. These are thirty-third degree members of the "Hospital" class. What of them? We cannot hold them in the face of their violation of our rules; we have to discharge them; usually we are glad to see them go. And yet of all consumptives they are the greatest menace to the public health. They drift from one sanatorium to another until the doors of all have been closed to them because of their own faults and mis-behaviour. No law, or at least none so plainly written that the average local board of health dares to enforce it, exists for the compulsory isolation of this type of patient. The legislature in its wisdom has repeatedly refused to pass such a salutary measure and yet without it much of the effort of the Commonwealth in the tuberculosis problem inevitably comes to naught. Furthermore, there is no place in which these patients may be so isolated. The sanatorium cannot hold a patient against his will. We have no option in the matter. So we find ourselves and you in your communities find yourselves with no real remedy against this very real and dangerous phase of the problem. Under existing conditions money expended on these individuals is thrown away. It is patients of this class who make the life of the superintendent of a sanatorium anything but a bed of roses. The very patients of all patients who ought to be held we are obliged to discharge back in their communities in order to preserve sanatorium order, decency and discipline.

Now is all this worth while? Does the Commonwealth receive an adequate return for its expenditures? Is sanatorium treatment worth while?

How shall we estimate the results except by the number of persons restored to health and earning capacity who return to their communities fit to resume their positions as productive members of the body politic; and by the educative influence which they exert upon those communities; and by the number of foci of disease removed from homes and communities.

With numerical statements I shall not bore or confuse you. We have them, however, and they bear out in every way the statement that the results do justify the expenditure of the large sums necessary to maintain and continue state sanatoria in Massachusetts.

In a paper appearing in the BOSTON MEDICAL AND SURGICAL JOURNAL under date of March 19, 1914, and the caption "Is Sanatorium Treatment Worth While?" Miss Gertrude L. Farmer of the Social Service Department of the Massachusetts General Hospital studied the results of sending 419 patients who appeared at that department to the state sanatoria. Her conclusions, in part,

somewhat changed as to wording but not in spirit or intent, follow:

"Owing to the limited number of beds provided in the Commonwealth for the care of its consumptives it is apparent that the State Sanatoria have so far played a relatively small part in caring for individuals. Their educative value cannot be computed. The discharged patients have carried the gospel of hygienic living to thousands. The day seems far distant when state care for the phthisical patient will be so organized that private societies can withdraw from the field. Only in few, if any, localities is municipal work able to fill the gap."

The gradual and continuous establishment of municipal hospitals and dispensaries, the beds in which already total almost 1500, will as time goes on slowly relieve the strain upon the state sanatoria and in a measure will fill the gap to which Miss Farmer alludes. Nor should we overlook the value of the work which has been done by the follow-up nurse employed by the Trustees of Hospitals for Consumptives in relation to patients discharged from the sanatoria.

Many have been restored to permanent, full time earning capacity; many have been restored permanently to part time working capacity; many others to temporary working capacity in full or in part; many others have been enabled to prolong their days on earth even if unable to resume productive labor; still again the last days of many more have been made comfortable and pleasant. The benefit to community health by the removal of inherently dangerous foci of disease through their isolation in state sanatoria cannot be adequately estimated although it must be great.

It is true that many cases upon returning to their homes fail to hold the gain which they made at the sanatorium; it is true that many are obliged to return to the sanatorium a second or even a third time; it is true that in the case of "incurables" most of our time, effort and money is wasted. On the other hand it is also true that many of these physical lapses are the direct result of improper home conditions, or of unhygienic surroundings in places of employment, or in the majority of instances, of the faulty spirit of the patient himself in neglecting to carry out at home the principles of treatment which he learned at the sanatorium. The sanatorium is not willing to assume the responsibility for such lapses under such conditions nor should they be charged against its account in the determination of its real value.

Beyond question restoration to health and working capacity is of great value and likewise is the removal of foci of dangerous disease but, it seems to me, beyond both of these is the importance of the key-note which Miss Farmer sounded, that discharged patients have carried and continue to carry to unknown thousands the gospel of the method of prevention of the spread of this most pitiful disease.

These three benefits bestowed by the sanator-

ium constitute the state's recompense for its expenditures and warrant the continuance of its efforts to relieve the burden of tuberculosis in this Commonwealth in spite of the fact, that cannot be denied, that the money, time and effort expended upon the "tramp," "malicious" and "incurable" types of patients, who obtain entrance to the sanatorium and pull down its standards, are absolutely wasted, which will assuredly continue to hold true until some other provision is made for such types.

Original Articles.

REMARKS ON THE DIAGNOSIS AND TREATMENT OF PULMONARY TUBERCULOSIS.*

BY BAYARD T. CRANE, M.D., RUTLAND, MASS.

DIAGNOSIS.

It was no less an authority than Sir William Osler who said that the family physician is a most important factor in the eradication of tuberculosis since he is the first to be consulted when illness arises.

This fact will stand extremely strong emphasis. In fact, is there a more important single principle in the entire tuberculosis situation today? In the future, compulsory examinations of a large part of the public may be adopted—examination of pupils, students, teachers, factory employees, club and lodge members, city, state and national employees—whereby the responsibility for recognition of this disease may be placed upon special agents chosen for this work, but until this or some other innovation is adopted, the indisputable fact remains that in this country the family physician, whether he wishes it or not, whether he realizes it or not, stands almost alone in the front rank, opposing the onslaught of this disease. Surely this is no light responsibility!

The profession in this State has improved in ability to diagnose early tuberculosis since the establishment of public sanatoria, albeit errors in diagnosis and delays in diagnosis are still rampant. Upward of four thousand (4000) persons die annually in this State of this disease and it is not proper to fail to realize that some of these deaths are due directly to the errors and delays in diagnosis.

The general practitioner is in an unenviable position—in fact he is, in my opinion, in an irrational position in that it is his expected task so to watch over the populace that he shall detect this disease (and that always early), freeing humanity thereby of its most dread scourge.

* Read at a meeting of the Worcester District Medical Society held December, 1914.

but he must do this by means of the bare diagnostic powers acquired during a general medical education.

We will not deny that the profession has made great advances in scientific accuracy in many lines, nor that it has many glorious conquests to its credit, all within recent years, nor will we deny a great adaptability and tolerance to changing conditions, but we can not justly expect the general practitioner to acquire and display expert medical knowledge in all branches of his activities, nor can he be expected to display refined diagnostic skill in branches which were not appropriately taught him in his student days and in which, since graduation, he has not had the necessary opportunities to perfect himself.

It seems to me that those who have "berated the general practitioner in season and out of season for his dereliction" have been too optimistic about the ease of acquiring the necessary skill to detect early tuberculosis, forgetting that they themselves spent months, and more usually years, in intimate contact with the disease before they unlearned the mis-conceptions they had previously acquired and before they considered themselves dependable to make an early diagnosis. Are we not, in short, straining for the impracticable and perhaps unattainable when we attempt to train the general practitioner, with his multiform duties, invariably to detect early tuberculosis?

I take it that it is hardly necessary to reiterate the profound advantages in material economy, and in human happiness, which result from early detection of this disease in comparison to detection in its later stages. I will merely state that seven times better results are obtained in incipient cases than in the far advanced cases, and four times better results are obtained in incipient cases than in the moderately advanced cases. It may be properly asked, "By what means, then, other than by the general practitioner, may the general detection of early tuberculosis be made?"

The reply is that no means yet employed can guarantee at once such general, invariable detection, but in some way specially trained physicians must come into intimate contact with the masses. As it is now in this country, examinations are made only with the voluntary consent of the examined and, in the case of the illiterate and uneducated classes, the cause of delays in diagnosis are largely due to this same illiteracy, lack of education and attendant poverty. By some method, then, it would seem necessary to make skilled routine examination compulsory among the illiterate and uneducated classes at least. This suggestion opens up a tremendous field for the operation of ingenuity, influence, and aggressive work on the part of the enlightened medical profession. Massachusetts, to hold its prestige, must hasten to take this advanced view.

Lastly, the general medical public must ac-

knowledge that modern tuberculosis has created a new order of things and that old principles are not comprehensive enough now.

The eradication of this social scourge must depend, as far as the profession is concerned, upon early detection *at any cost*, and then upon an insistent, aggressive mastery and thorough control of the patient, also *at any cost*, until he is wholly well or at least until perfectly trained as to his responsibilities and power of infecting others.

To carry out these requirements, the medical profession must possess courage, insight, industry, and at times, self-sacrifice.

Hazy doubts in diagnosis should be cleared away promptly by consultations, and if a complete control of the patient is not possible at home, he must be sent away where sufficient control can be had.

What are the causes of failure to detect tuberculosis?

They are the same cases that have existed from the outset, though it is undoubted that they are gradually diminishing. They still consist of

- (1) Delays in making diagnosis, and
- (2) Errors in Diagnosis.

DELAYS IN DIAGNOSIS UNTIL THE DISEASE HAS PASSED BEYOND THE EARLY STAGES.

The delays arise most often, I believe, from inability to detect the slight changes from the normal in physical signs and symptoms, but they also arise from a failure to apply the findings to their logical place. It is a case of the absence of a clear, accurate mental picture of tuberculosis in its outset. To be able to detect early tuberculosis requires a talented use of the stethoscope, a keen ear, and a power to discriminate between the normal and a slight variation from the normal in many bodily functions.

It is difficult to make general interpretations on this subject, but it is justifiable to state that there still seems to be an adherence to the older traditions and teachings about "Consumption" that existed before sanatoria were established, and we continue to make our diagnoses on such clinical symptoms as correspond and co-exist in the types of tubercular lesions which we had pointed out to us in our student days. In those days tuberculosis was taught chiefly in the pathological and post-mortem departments. The clinical histories that corresponded with those cases so often mentioned high temperatures, emaciation, hectic flush, profuse expectoration, night sweats, and cavities that *now* our minds are too prone to cling to those symptoms as belonging to all cases of tuberculosis.

But such is radically erroneous. Our early favorable cases usually present not one of these symptoms. These symptoms arise usually as the lung begins to break down and are generally indications of a late stage or of an acute process.

Truly incipient cases have "slight infiltration limited to the apex of one or both lungs, or a

small part of one lobe; slight or no constitutional symptoms (including particularly gastric or intestinal disturbance or rapid loss of weight), slight or no elevation of temperature or acceleration of pulse at any time during the twenty-four hours; expectoration small in amount or absent; tubercle bacilli may be present or absent and there are no tuberculous complications."*

Another cause of delay in diagnosis is the tendency to lean upon the laboratory report, assuming that a positive sputum report is essential. Speaking at random, far less than one quarter of the cases admitted to sanatoria require a diagnostic sputum test, because the clinical history and physical signs are sufficient generally in the hands of an experienced tuberculosis practitioner to make the diagnosis.

It seems puerile at this date to reiterate that the patient's clothing should be removed to the waist during examination and that each spot should be auscultated after a forced cough followed by full inspiration and expiration.

Among the gross, more readily elicited diagnostic signs, occurring in many favorable cases but rarely in the really incipient, is a lack of expansion on the affected side. To elicit this, the patient should be exposed directly in front of a single source of bright light and asked to take a full breath while sitting or standing with hands in the lap and knees not crossed.

The excursion of the angle of the scapula and of the nipple on the affected side will be often appreciably diminished. This sign is not to be depended upon except to suggest or corroborate tuberculosis, and naturally is not as marked in early as in later stages.

Another comparatively easily elicited sign is an increase of intensity of the respiratory murmur over the affected area. A still more accurate gross sign is the more high pitched or intense whispered voice over the affected area.

The use of hypodermic tuberculine for diagnosis should not be undertaken by one who has not the ability to make a skilled physical examination.

ERRORS IN DIAGNOSIS.

The commonest errors of diagnosis are Bronchitis, Pleurisy, "Grippe," "Bleeding from the throat" and "Debility." In regard to the first (perhaps the most common) I would advise one invariably to be skeptical of the diagnosis of a benign bronchitis, and more especially, to assume that unilateral "bronchitis" is tuberculosis.

"Pleurisy" in most cases accompanies parenchymatous involvement or is an independent tuberculous process.

So-called "Grippe" frequently ushers in frank tuberculosis, and "bleeding from the throat" is so nearly invariably due to tuberculosis that the invariable first assumption should be tuberculosis. It may appear as mere specks, as a diffused pinkish discoloration of a small mass of sputum,

* Vide: Classification adopted by the National Association for the Study and Prevention of Tuberculosis and by the American Sanatorium Association.

as a few bright streaks in the sputum, or as a chocolate colored or blackish, mottled mixture. These small blood spittings are often a most fortunate episode in the case as they are quite apt to disturb the patient sufficiently to rouse him to see a physician.

Some of the more rare symptoms of pulmonary tuberculosis are dyspnea, mental irritability, languor and weariness. Psychasthenia often develops as tuberculosis appears. I would urge a sharp lookout for this condition, more particularly in women, so that such treatment as may be instituted will be in harmony with this condition and so that the patient's comfort will be most fully protected. The psychasthenia may take the form of fears, apprehensions, depressions, or hallucinations, and in these cases isolation and bed treatment, individualization and an harmonious environment will be very valuable.

TREATMENT.

It may be well to take a general review of events as they have occurred in the tuberculosis field (chiefly in this state), calling attention to progress and failure so that we may the more wisely deal with the problems of the future.

In 1885, Dr. Edward L. Trudeau established the Adirondack Cottage Sanitarium, thereby introducing sanatorium treatment into this country. The modern kind of tuberculosis activities in this country may be said to have begun there and then. This noble man was a worthy sponsor of a great cause.

In establishing his institution in the mountains, he adopted the theory of the beneficial effects of altitude and of inland climate in the treatment.

In February, 1891, Dr. Vincent Y. Bowditch established a sanatorium in Sharon, Mass., at a general elevation of about 300 feet, and achieved remarkable success. Influenced chiefly by this success, the State of Massachusetts elected to try the experiment of treating favorable cases of tuberculosis under its own supervision. It chose a site at an elevation of about 1200 feet in Rutland and appointed Dr. Bowditch and others to its medical staff.

This State Sanatorium, doing pioneer work, achieved such success and popularity that a country-wide policy of establishing State Sanatoria soon followed.

But after a few years of effective operation, outside words of criticism and disappointment were heard. The criticism was aimed at the incompleteness of the benefit received, or, in other words, to the tendency to relapse which some patients showed after discharge from the sanatorium, and incidentally the climate and altitude and other things took their share of criticism. The criticism accumulated and finally assumed the proportion of definite counteracting and corrective propaganda.

Home treatment, even in crowded cities, in congested quarters was enthusiastically hailed.

Day camps were established in many large cities, regardless of altitude and climatic conditions. *Tuberculosis classes* were instituted in Boston and adopted in many large cities of other states. *Tuberculosis dispensaries* took on new expansions. Even the State Tuberculosis Commission, then reorganized, showed the existing discontent at sanatorium results as realized at Rutland by using considerable pressure to utilize the then-building three new state institutions for the reception and treatment of favorable cases on a par with Rutland, though these institutions had been located with slight regard to climatic advantages, but chiefly so that they might be near populous districts.

At about the same time, to one who had followed the trend of the annual meetings of the National Association for Study and Prevention of Tuberculosis from the outset, a lull of enthusiasm became apparent in its meetings.

All these conditions were tending to establish a real belief that sanatorium treatment was not as valuable as it had been claimed by the originators and that non-institutional treatment was as good, and that all climates and all kinds of climate were equally valuable in curing tuberculosis. This belief prevailed for several years. Since then, however, class treatment has been largely abandoned, day camps have fallen from grace somewhat and some, who had enthusiastically endorsed home treatment, have since become equally enthusiastic over the great curative power of the bracing, clear air of hills and mountains.

These facts are significant and can all be explained readily. The corrective propaganda were tried out and found less capable of producing results than sanatoria had been.

It is today to be noticed wherever experienced tuberculosis workers of all kinds gather (social workers, district nurses, dispensary physicians, city physicians, clinicians and sanatorium workers) that there is a prevailing general conviction *that patients should first go to a sanatorium* because of the better chance of cure there obtained and because of the more thorough health education there received. In other words, *good sanatoria were never so popular as today*. Stated in other terms, it is now recognized quite generally among tuberculosis workers, after impartial trial of various agencies, that sanatoria are fixtures as long as tuberculosis exists, and that in the great preponderating majority of cases, those patients are far more fortunate who can have the advantages, during a part of their treatment at least, of a good sanatorium. Before long the same conviction may be expected to take possession of the profession at large, and coincidentally, I venture to say, will the tuberculosis death-rate show a more rapid decline.

It is not easy to explain convincingly the reasons why institutional treatment produces better results than home treatment, yet an analysis of the individuality of the disease will reveal some peculiarities which certainly would suggest the

probability that institutional treatment would be preferable.

1. For instance, the disease is *subtle* and *insidious* and is not accompanied with marked bodily distress. Hence the patient is apt to overlook a backsliding in his health until it has become marked and serious, but if he is in an institution he is under the frequent observation of nurses or physicians who are trained to detect slight variations of symptoms.

2. *Regularity of routine* seems to be a valuable element of treatment and it is quite apparent that a home can rarely be systematized to operate with the precision of an institution.

3. There is a large element of *effort* and *task* about the treatment when properly pursued. It is apparent that with the family at hand, the patient may be often excused from the effort when an institution would insist upon it.

4. At home the patient is bound to be brought in contact with *petty cares* and *annoyances* of which he would probably be ignorant if he were away.

5. The treatment is a *tedious, long continued* process, during which the fund of moral support, wise counsel and patience of a family may give out.

6. The treatment is *progressive* and requires frequent alterations of orders by the physician, but if at home the patient, when feeling well, is apt to consider a visit from the physician as an unnecessary expense.

7. *Education about the disease* by observation of other patients is to be had in an institution and not when taking treatment alone.

These are some of the reasons of preference for sanatoria. In a small percentage of cases, temperament is such that institutional treatment must not be thought of.

Sanatoria, then, stand as the chief means of treatment of the disease, and yet it is all too apparent that sanatoria can never eradicate the disease alone. All the combined methods of attack upon the disease, including better housing, cleaner cities, public parks, pure water supply, open air schools, out-door sleeping, shortened hours of labor, cleaner milk, hospitals for incurables, fumigation of apartments, prohibition of spitting, etc., etc., have made a strong impression, but apparently the greater part of the task still remains undone.

To return to the subject of the sanatorium patient, I would reiterate that the extent of control of his disease on his discharge (with consent) is limited to an *arrest* but not a cure. The sanatorium at best has subdued, but not eradicated his disease and has educated him into better methods of living, but the purely sanatorium duty stops there. What happens to him after discharge cannot rightly be the responsibility of the sanatorium.

In many cases the disease relapses after discharge. *The after-care of the consumptive is the weakest point in our whole scheme today* and

little has been accomplished to improve this defect.

Shall the patients who came from unsanitary homes and whose previous work is now unsuitable for them, be sent to work colonies, supported by the state, for physical training to fit them for the requirements of the general labor market and for manual training in more healthful occupations?

Until some comprehensive solution of the after-care problem is made, it is well to keep in mind that arrested and non-arrested cases are returning into our midst with need for wise medical counsel.

The treatment of a curable case of tuberculosis may be divided into two distinct stages:

In the first we must create and maintain such a form of living by the patient as will build up a controlling resistance to the tubercular toxine and establish a normal degree of nourishment, by means of such a readjustment of his habits and of the actions of the leading organs of his body as will maintain the toxine resistance and normal nourishment even under moderate activity. When this is accomplished the disease is arrested. In practice this will require an aggressive, alert, patient, optimistic resourceful, skilful action on the physician's part. This may well be called the sanatorium phase of the treatment and is well comprehended and indicated in the word "*sanatorium*," which comes from the verb "*sanare*," to heal.

The second stage of treatment is quite different. It is planned on the principle to hold ground already gained until cure is established or arrives. It is less aggressive than the first phase and is more accurately a problem of *prophylaxis*. Its chief aim is not to improve on what has already been accomplished in improved habits and bodily functions, but to prevent the reappearance and re-establishment of any form of bodily overtax.

The first stage will require of the physician ability to note and interpret the changing physical signs and symptoms, and a knowledge of the influence of rest and exercise upon the pathological process, a knowledge of foods and of the action of air upon the body.

The second stage will more particularly require a knowledge of the normal in housing, hours of work, sanitary conditions and food, and incidentally will reveal the fact that society, though partly responsible for the patient's illness, yet adheres to such prejudices against him that he faces severe restrictions and finds few avenues for the use of his talents.

The one who assists in this prophylaxis of tuberculosis must do his part then in social uplift work, but so intertwined is tuberculosis with all the great human problems, of the individual and of the community, that changes of great magnitude, entailing colossal outlay of money and effort, must doubtless be wrought before this scourge shall be cast off.

Consider alone the outlay necessary to bring housing conditions up to a healthful point in our cities. More than almost any other disease tuberculosis possesses social phases, and the physician who comes into even occasional contact with it may well pause to consider whether in his handling of a case the obligations to society are properly considered. We have the opportunities and abilities to see clearly the basic causes of this far-reaching scourge. Our position has enabled us to trace out the human faults and deficiencies that produce the thing. No other profession, no other group of people, knows so well when humanity begins, by its omissions and commissions, to endanger itself with this trouble. Ours being the first eyes to see the impending misfortune, so also is ours the duty to warn early against the dangers,—to counsel in private and public the truths we know, to teach, to preach, to educate,—to create, in short, public enlightenment.

Let the profession realize that the pioneer tuberculosis physicians have known well what they needed in state institutions to make success, but that they must wait for the consent of legislative bodies. Let us realize that slow progress can often be traced to bad politics and we will see clearly what the remedy is.

Help to disseminate the information that able physicians often shun public institutions because of the dangers and futile obstacles therein.

Able hospital superintendents deserve co-operation and support from the profession. The percentage of recoveries being dependent greatly upon a complete authority and control of patients, it follows that coöperation by the profession with the hospital staff will assist to increase recoveries by establishing confidence and co-operation between patients and staff. We should attempt to aid the staff to have untrammelled authority and power.

Let us have a policy in regard to our city and county tuberculosis hospitals. These are chiefly isolation places, and the management will require chiefly palliative measures until the end. But some curable cases may enter here, and for them an aggressive, particular routine must be instituted or they may fail to recover.

MORTALITY AFTER PROSTATECTOMY, BASED ON A STUDY OF 229 FATAL RESULTS.*

By BENJAMIN TENNEY, M.D., BOSTON,

AND

HENRY M. CHASE, M.D., BOSTON.

The observations which this paper presents are obtained from the consideration of 106 fatal cases following prostatectomy contributed for our

* Read at the annual meeting of the American Urological Association in Philadelphia, 1914.

study by members of the American Urological Society, from other cases already in print and from a paper on Mortality after Prostatectomy published by us in 1906.

As many of the reports cover cases dying before our modern methods of investigation became common and others have been made up from incomplete records, the totals of the different observations vary. It may be regretted that this paper does not cover the percentage of recoveries as well. Possibly this may be taken up at another time, but this paper will be confined to a study of fatal cases and their relation to the conditions which existed before operation.

We have discarded the reports on cases operated under fifty years of age as likely to be complicated by acute infection of the urinary tract and by cancer. One hundred and sixty cases arranged by decades with the cause of death appear in Table I.

Table I

	50-59	60-69	70-79	80-89	90	Totals	Cases from Previous Paper	Totals
Uremia	7	15	16	3		41	25	66 30%
Sepsis	1	9	8	1		19	6	25 11%
Hemorrhage	3	10	13	4		30	11	50 22%
Shock	1	3	5			9		
Embolism	3	12	7	2		24	3	27 12%
Pulmonary	1	3	5	4	1	14	8	22 10%
Cardiac	1	4	6	1		12	9	21 9%
General Debility		3	2	1		6	1	7 3%
Acidosis		1	1			2	0	2 1%
Accident	1	2				3	6	9 4%

It appears that there were more deaths from uremia than from any other one cause. We have listed the deaths from sepsis next because some deaths assigned to this cause occurred so early as to suggest the influence of renal inadequacy in producing so early fatal results. Legeu goes even further and in a recent paper says: "Minute investigation of the conditions under which prostatic patients die compels us to attach more and more importance to renal insufficiency. Death from uremia fully explains the accidents currently ascribed to embolism or pulmonary complications which in reality only play a secondary part. It would seem that alongside and vastly more than the liver, lung and heart it is the kidneys which most frequently kill our patients after operation and which furnish the underlying cause of many of the pathological troubles in those who recover."

The next most frequent cause of death is hemorrhage and we have listed shock after this because the two are so often associated and because some patients who were said to have died of shock lived for twenty-four hours or more before the end came.

It is our opinion that a reduction in mortality from these two causes is possible and that a dis-

tinct improvement over the results of ten years ago is already here.

The large number of deaths between sixty and eighty corresponds with the larger number of patients who were operated in these decades. Our previous paper, based on 816 operations by many different surgeons, showed that 80% of all prostatectomies were done on patients in these two decades. It may be interesting to reproduce the table from that paper showing the mortality in the different decades.

= TABLE II =

	50-59	60-69	70-79	80-89	90
Number of Patients	120	422	240	24	2
Percentage of Fatal Operations	5.8%	9.5%	15%	33%	50%

This table was made up from ninety-one fatal results in the work of many different operators with a general mortality of ten per cent.

DURATION OF OBSTRUCTION.

There are 100 cases in which the duration of obstruction can be compared with the cause of death.

Table III

	Duration of obstruction up to one year	One to three years	Over Three years.
Uremia	9	5	15
Sepsis	5	1	4
Hemorrhage	5	7	13
Shock			
Embolism	5	2	7
Pulmonary	0	6	3
Cardiac	1	1	6
General Debility	0	1	2
Accident	0	2	0
Total	25	25	50

The larger proportion of deaths from uremia, sepsis and embolism in patients operated within a year of obstruction, suggests that patients with impaired renal and circulatory apparatus are more likely to seek help early than those who have no disabilities outside of the bladder.

PREPARATION UNDER HOSPITAL CONDITIONS.

There are 101 cases in which the preparation under hospital conditions can be compared with the cause of death.

TABLE IV
PREPARATION

Cause of Death	Two days or less 44 cases	3-7 Days 30 cases	8-14 Days 20 cases	Longer 10 cases
Uremia	16 = 37%	9 = 30%	5 = 25%	3 =
Sepsis	6 = 14%		3 = 15%	1
Hemorrhage	7 = 16%	8 = 27%	4 = 20%	1
Shock		1 = 3%		
Embolism	9 = 20%	3 = 10%	5 = 25%	1
Pulmonary	1	3 = 10%	2	
Cardiac	3 =	9 = 10%	1	4
General Debility	1			
Acidosis				
Accident	1			

The diminishing percentage of deaths from uremia, as we compare the immediate operations with those delayed is certainly suggestive of the desirability of preparation before operation.

Along this same line it appears in Dr. Hugh H. Young's monograph of 1906 that while some few of his patients were operated within a day or two of admission, there was an average delay of more than eighteen days. You will remember that he reported seven deaths in a total of one hundred and forty-five cases.

PRELIMINARY DRAINAGE.

Thirty-six of these fatal cases were drained by catheter and ten by cystotomy before the prostatectomy. Drainage varied from one to ninety days. Fifteen were drained less than one week.

= TABLE V =

	Catheter Drainage Cases	Cystotomy
Uremia	10	5
Sepsis	3	1
Hemorrhage	8	1
Shock	2	
Embolism	7	1
Pulmonary	4	1
Cardiac	1	1
General Debility		
Acidosis		
Accident	1	

These cases show nothing except that the drainage used was not adequate to protect them from the usual proportion of deaths from uremia, hemorrhage and embolism. It is a question whether drainage for less than a week makes any material difference in the condition of the bladder and kidneys.

If we are to drain before operation we should do it for a certain effect rather than for a certain number of days. If there is any reason for using drainage in preparation of patients that reason should be removed before drainage is given up. The replies to our question are too few to show anything as to the comparative value of long and short preliminary drainage.

FUNCTIONAL TESTS.

The results of functional tests are reported in twenty-six fatalities.

= TABLE VI =

	Cases with Functional Tests	General Percentage
Uremia	10%	30%
Shock and Hemorrhage	10%	22%
Embolism	23%	12%
Sepsis	4%	11%

The functional tests reported are phenolsulphonephthalein and urea percentage, the latter in two cases only.

We regret that the number of fatal cases in which some adequate test of renal function was

made is so small as to be no test of the value of any of these recent methods. It does appear, however, that the percentage of deaths from uremia and sepsis is smaller among cases tested than among the general run of cases. We believe that the rapidity with which the phenol-sulphonephthalein appears in the urine is of great value in estimating the progress made by a patient during his days of preparation. The new ferment which makes the estimation of urea in the blood and urine comparatively easy will doubtless bring the "uremic constant" into frequent use on this side of the ocean. No report of its use has come among these cases.

The hemoglobin test is reported in eighteen cases only. Four having hemoglobin of 80% or better died of hemorrhage; six with hemoglobin, between 70% and 80%, of uremia; four with hemoglobin of 80% or better died of embolism.

The blood pressure is given in thirty-one cases. Of those with pressure of 200 or over two died of uremia, one of hemorrhage and one of sepsis. Of those with pressure of 140 or below three died of hemorrhage, one of embolism and one of cardiac disease.

The presence of edema is mentioned in only four cases.

In nearly all the cases dying of hemorrhage the mental condition is given as "Good" or "Fair." In the cases dying of uremia the mental condition is given as "Good" or "Impaired."

The effect of "clean bladder" in twenty-six cases is not apparent, one case dying of sepsis which is not far from the general proportion.

ANESTHESIA.

The anesthesia is reported in 106 cases.

Table VII
= Anesthesia =

	Ether	Spinal	Nitrous Oxide	Chloroform	Local	Gas Ether Chloroform
Uremia	15	6	4	6	2	
Sepsis	4	1				
Hemorrhage	14	1				1
Shock	5					
Embolism	17	1			1	
Pulmonary	5	1	4			
Cardiac	3	2	1	1	1	
General (Debility)	2	2	1	1		
Acidosis			1			
Accident	2					

The proportion of deaths from uremia under chloroform and spinal anesthesia is larger than with the other anesthetics which may or may not be due to using these in the worst cases. Certainly neither anesthetic gives perfect security against death from this cause.

The causes of death as related to the type of operation appear in the following table.

Eleven fatalities following the two stage suprapubic operation, and seventeen following the transcapsular perineal operation are included in the above tables as both show the usual causes of death and do not materially alter the above figures. If we may regard the deaths from

TABLE VIII

	Suprapubic	Perineal
Uremia	18 = 22%	19 = 31%
Sepsis	4 = 5%	8 = 13%
Hemorrhage and Shock	16 = 21%	17 = 28%
Embolism	13 = 20%	7 = 11%
Pulmonary	9 = 12%	6 = 10%
Cardiac	8 = 10%	2 = 3%
General Debility	4 = 5%	
Acidosis		1
Accident	2	

uremia, sepsis, shock and hemorrhage as being more likely preventable than those from other causes, it is worth noting that 48% of the deaths following the suprapubic route were from these causes, which may be compared with 72% in the perineal fatalities.

GENERAL CONSIDERATIONS.

The three cases dying of accident were one from embolism following air distention of the bladder, one of sudden death with ether anesthesia while the patient was in the Trendelenburg position, and one from distention of the abdominal cavity by irrigating fluid used after the operation.

Under the heading of general debility we have included one case said to have died from acute dilation of stomach.

COMMENTS.

"I am satisfied that air absorbed through the bladder walls or through a prostatic lesion was the cause of this man's death. I will never use air distention again."

"It is my opinion that the pressure of the perineal drainage tube on the purulent open vein field of the prostatic urethra forced the pus with blood clot into the veins on getting the patient out of bed, and this was followed by an embolic pneumonia and death."

"This patient was operated in a town nearby. I left the day after operation. I have since made it a rule never to operate away from home save in emergency."

"In talking with the various men doing this kind of work, I find that some insist that they will never operate outside of the hospital. I have seen cases in farm houses where something had to be done for relief immediately and where the suggestion of removal would not be listened to. I question very much whether some one will not have to do certain cases outside the hospitals."

"It is to be noted that I have never lost a private patient. All my deaths have occurred in hospital cases in which I was unable to secure the sort of pre-and-post operative treatment upon which I cannot but think so much depends in the question of death or recovery."

SUMMARY.

The greatest danger in the operation of prostatectomy is death from uremia or from condi-

tions closely associated with it. After examining a patient we should be able to say that he is a good, fair, or poor risk with reference to this condition. If he is not put in the first class, we should try to put him there before operation or at least get him as near there as possible. Three fatalities from uremia reported to us in patients who had been carefully treated for more than two months, show that we cannot always succeed, but the percentage of deaths from uremia among the cases operated within two days was 37%, while the percentage of deaths from the same cause among patients who were observed long enough to have functional tests made was 19%.

The second great danger in this operation is death from hemorrhage and shock. Is it possible that in our desire to avoid shock by doing a rapid operation, we have sometimes produced shock and hemorrhage by doing a needlessly rough operation? There are reasons in the reports sent us for thinking that this may have had some influence. It is fair to say that a patient whose hemorrhage has been thoroughly controlled seldom starts bleeding again unless the gauze or other means of control is removed too soon. Possibly some operators have been disappointed at nature's failure to stop a leaking vessel which they had failed to close before the patient left the table.

The third serious fatality is embolism, which may also be the cause for some pulmonary complications.

How can we avoid at least a portion of this risk?

Blood vessels are necessarily torn and left untied. The wound is in an infected region and constantly bathed in a septic fluid. A larger raw area is left exposed to this contamination than in almost any other operation. Constant irrigation does not prevent embolism. It occurs when perineal, urethral and suprapubic drainage tubes are used and after both operations. Is it possible that our well meant drains are responsible for some of these emboli as suggested by Dr. Barnett?

Suprapubic tubes long enough to rest in the prostatic cavity and perineal drains reaching the same distance are well placed to disturb the clots in the surrounding veins as the patient moves about. Is there any need of tubes after either operation? There will be no back pressure of urine with a good sized opening in the bladder and we would welcome an early closure of the incision we make, provided the patient does not suffer thereby.

The deaths under the heading of Cardiac and General Debility are many of them uncertain. Some with autopsy would have been called uremic and some embolic. Some apparently represent the general giving out of the machine after the accident of prostatectomy and some a myocarditis.

It is not yet possible to say what the mortality of the operation should be because operators

have such varied methods in their selection of cases.

A surgeon who believes that every old man suffering from prostatic obstruction is entitled to a chance of operative cure will have a higher mortality than the surgeon who refuses the desperate cases.

One skilful operator says privately that by selecting his cases he has done over ninety prostatectomies with one fatal result, and in contrast there is a mortality in some excellent hospitals of 20% or more. It is certain that the mortality rate is lower than it was ten years ago and a large credit is due Drs. Rowntree and Geraughty's study of color elimination in its relation to renal competency, for the improvement.

Before this work appeared many of us knew the wisdom of preliminary drainage but now we have a measure of the time necessary for this. Until some better method is made applicable, no prostatectomy should be done without testing the capacity of the kidneys for color elimination, using some chemical at least as reliable as phenolsulphonephthalein. By this intelligent delay many cases can be transferred from the desperate to the reasonably safe class of risks and those truly inoperable can obtain some measure of relief from their misery.

A STUDY OF THE EFFICIENCY OF MIXED TOXINS (COLEY) IN INOPERABLE SARCOMA. A CRITICAL ANALYSIS OF 134 MICROSCOPICALLY PROVEN CASES.

By TORR WAGNER HARMER, M.D., BOSTON,

Assistant in Anatomy, Harvard Medical School; Junior Assistant Surgeon, Children's Hospital; Assistant in Surgery, Massachusetts General Hospital.

(Concluded from page 446.)

CASE REPORTS.

BONE (Not Giant Cell).

CASE 86. (Case No. 41. and *Annals of Surgery*, 1913, vol. lviii.) Periosteal round cell sarcoma of femur with multiple metastases. A. G., 18, male. An extensive growth involving lower two-thirds of shaft of femur proved on microscopical examination to be small round cell sarcoma. Amputation at hip joint refused. After prolonged x-ray treatment, extensive metastases developed in pectoral and ilio-lumbar regions, involving ilium. Pectoral mass partially excised.

Pathological report. Round cell sarcoma. Toxin treatment instituted. In four weeks ilio-lumbar growth became necrotic and was drained. No trace of recurrence 10½ years later. Subsequently there developed epithelioma at site of x-ray dermatitis on chest and malignant tumors (epithelioma and sarcoma) at sight of x-ray dermatitis on thigh. The latter grew rapidly. Amputation was refused. Lung

metastases developed and the patient died. Recorded in Group C.

CASE 87 Personal case. Referred by Dr. Conant. Chondro-sarcoma of tibia with metastases. F. McH., an Irish stableman of 26.

Oct. 22, 1912. Gives following history. One and a half years ago growth appeared in right shin, increased to size of grape fruit, and was excised. It recurred within nine weeks, since which time it has been slowly and painlessly growing. Four days ago hemoptysis with pain in right chest. There is a slight dulness at right base with diminished respiration and tender area in posterior axillary line. A large firm mass involving whole leg just below knee, size of child's head, with ulcerated area about four inches in diameter. Markedly enlarged glands in groin.

Oct. 28. Dr. Conant amputated leg at mid-thigh under spinal anesthesia to rid patient of foul mass and prevent hemorrhage.

Pathological report. (1210-142) Dr. Whitney. Chondro-sarcoma. A lower extremity showing a tumor at calf with ulcerated surface. Section shows it infiltrated with muscle and fat, having a reddish-brown surface which in places was bony. Further section shows periosteum of tibia eroded by tumor growth. Section of tibia shows yellow marrow with firm cavity. Fibula not involved. Knee joint free. Enlarged lymph nodes from groin. Microscopical examination shows irregular area of hyaline cartilage, in places, however, with very abundant cells but without any definite type of structure.

Treatment with mixed toxins started three weeks later and continued $3\frac{1}{2}$ months. Maximum dose, 14 minims. Injections every two or three days. Reactions marked. Shortly after treatment started recurrence appeared on anterior surface of stump. This diminished in size but for last month unaffected by toxins. During period of diminution of recurrence there was no cough or pain in chest but three months after starting toxins patient had attack of chest pain with hemoptysis and from this time until treatment discontinued (March 6, 1913) patient steadily declined and recurrence on stump steadily progressed. Recorded in Group B.

CASE 88. (*Annals of Surgery*, Nov., 1914, p. 559.) Inoperable mixed cell sarcoma of clavicle and breast. R. B., male. Mass of two years' duration occupying whole left pectoral and axillary regions. Markedly protuberant and of variable consistency. Just above clavicle growth about size of hen's egg. Toxin treatment for two months with diminution in size and marked softening. Incision for drainage. Soon after toxins were discontinued the growth became rapid. Radium of no avail. Death. Recorded in Group B.

CASE 89. Personal case. Referred by Dr. Scudder. Small round cell sarcoma of tibia. Recurrent. M. B., a school girl of 15. House No. 180922.

Feb. 7, 1912. Three months ago fell wrenching but not striking right knee. Pain in knee persisted and in three weeks a swelling was noted just below the joint, motion became limited, and for past month has been confined to bed. Examination shows diffuse enlargement of right knee, slightly tender, not inflamed, no fluid in joint. X-ray shows typical periosteal sarcoma.

Feb. 10. Amputation at mid-thigh by Dr. Scudder.

Pathological report at time of operation. Small round cell sarcoma (Dr. Whitney).

Subsequent pathological report (122-42.) A leg amputated at thigh. Section in popliteal space shows a dense white tumor size of hen's egg grating under the knife. Microscopical examination of growth shows it to be composed of round cells with a rather homogeneous intercellular substance, in places infiltrated with lime salts, but nowhere with any true bone. Osteoid-sarcoma.

Nine days later toxin treatment started and continued every second or third day for 25 days. Maximum dose, 3 minims. Reactions good. Toxins then refused. Four months later (July 25) seen with recurrence in the stump, a deep mass about 1 by $1\frac{1}{2}$ inches, firm and fixed to deep tissues. X-ray shows periosteal sarcoma.

Toxin treatment resumed and continued one month. Injections every other day into tumor. Reactions sharp. Maximum dose, 16 minims. Although patient was having good reactions the growth was steadily increasing in size and the patient's general condition becoming much poorer. Died three months later (Nov. 18, 1912) of metastatic pneumonia and pleurisy. Recorded in Group A.

CASE 90 Personal case. Referred by Dr. Channing Simmons. Multiple periosteal sarcomata. L. E. S., a Portuguese barber of 19. House records W. S. vol. 637, p. 49 and vol. 671, p. 221.

July 15, 1909. Six months ago noted pain in left leg followed by "thickening of the bone." No known injury. Growth steady with very little pain. Now a hard non-tender fusiform swelling of mid-third of tibia about three times former size. July 16, amputation just below mid-thigh by Dr. Lothrop.

Pathological report. (97-45.) Periosteal sarcoma. Dr. F. C. Kidner. Left leg amputated just above the knee. Symmetrically involving the mid-third of the tibia is a hard, fusiform osteoid tumor rather cellular in appearance. The tumor partially involves the muscle. On section of the bone it is apparent that the growth is invading the medullary cavity. The tissue of the tumor is grayish in color. Microscopical examination shows masses of osteoid tissue with very small amounts of lime deposit and irregular and atypical cells. In the meshes of this badly formed bone lie masses of ovoid irregular cells, whose protoplasm shows many fibrillae extending from cell to cell. The cells are rather large and nuclei dense.

July 23, 1910. Patient reports with history of being well until six months ago when noticed pain and swelling in left shoulder. When shoulder had attained twice normal size pain ceased. For one week considerable pain in right shoulder. This he attributes to use of crutches. There is a fusiform symmetrical enlargement at left shoulder, size of very large grape fruit, extending from deltoid insertion up over acromion and coracoid. Smaller similar mass at inner end of right clavicle.

Treatment with mixed toxins started and continued three months. Injections every second or third day with good reactions. Patient's condition and size of masses about the same. Consistency of masses somewhat softer. Patient then returned to local physician, Dr. E. W. Smith, then of Provincetown, Mass., now of Boston, who continued toxins under my direction for six weeks. Maximum dose, 14 minims. Tumors still increasing in size when toxins omitted.

A letter from Dr. Smith Nov. 25, 1913 states that he believed the condition unaffected by the toxins. The left clavicle became involved and grew with the tumor of the right clavicle to such size that the patient was unable to turn his head. The growth of the humerus attained enormous proportions so that a specially constructed casket was necessary. He died June 12, 1911. Recorded in Group A.

CASE 91. Personal case. Referred by Dr. W. J. Mixer. Fibro-sarcoma of spine.

C. J. D., clerk, 43. May 24, 1913. Gives following history. For a year feeling of strain of back. Diagnosed as lumbago. Two months later drawing pain in front of left thigh relieved by lying down. One month ago numbness and severe pain of left leg which has persisted. Upper lumbar region shows stiffness and pain on motion; tenderness to pressure. Slight left scoliosis. No mass. Left knee jerk, absent. Reflexes and sensation otherwise normal.

May 25, 1913. Operation by Dr. Mixer. Laminectomy of first and second lumbar vertebrae, exposed a tough, infiltrating growth involving bone. Impossible to remove wholly.

Pathological report. (135-117) Dr. W. F. Whitney. Fibro-sarcoma with giant cells. A few rather firm, rather grayish fragments with muscle and a little tissue. Microscopical examination shows growth of fibrous tissue, in places quite cellular with rather hyaline fibers and here and there areas of scattered giant cells.

Treatment with toxins started in 12 days and continued for 7½ weeks, injections every other day. Maximum dose, 24 minims. Reaction after first fortnight marked, but mass became evident at operation scar and grew rapidly with development of complete paralysis of both legs. Treatment continued until day before death. Recorded in Group A.

CASE 92. Personal case. Referred by Dr. C. L. Scudder. Mixed cell sarcoma of lower jaw. Mrs. W., 32.

For 4½ weeks swelling of jaw accompanied by neuralgia of right side of face and beneath eye. Pain not great. Examination shows a swelling size of apple on outer side of right jaw, extending into mouth, with pus exuding from around teeth in this region. X-ray shows osteomyelitis. Mass is firm in places and in others somewhat fluctuant. Evacuation through incision in mouth. Tissue removed; evidently necrotic malignant disease.

Pathological Report. Sarcoma.

Sept. 9, 1914. Dr. Scudder performed a resection of one-half of lower jaw with removal of mass in mouth. Cervical glands not enlarged. Mouth mucosa sutured tight. Small drain in neck. Patient made a satisfactory convalescence.

Pathological Report (Dr. H. F. Hartwell). Osteoid sarcoma. The tumor of the jaw received on Sept. 9, consisted of a round, irregular mass about the size of a tennis ball. It was firmly attached to a portion of the ramus. On side was a foul necrotic mucous surface. A portion of the bone which was enveloped by the tumor was atrophic and friable. Section of tumor on the surface away from the mucous membrane showed a grayish-white firm substance. Microscopical examination of a number of sections showed a richly cellular tumor made up of large undifferentiated round cells with considerable eosin staining intracellular substance.

The nuclei were of large size and showed numerous mitotic figures and occasionally cells were seen containing several nuclei.

Nov. 4 patient seen with Dr. Scudder with recurrence size of crab-apple, firm, bluish-red, extending into floor of mouth. Mixed toxin treatment started following day and continued until Dec. 9 (5 weeks). Patient exhibited but little tolerance for toxins. Maximum dose 4 minims. Reactions always severe. Toxins without effect. Mass grew steadily in size, became quite soft and was early drained through incision in neck. X-ray treatment started. Despite massive doses every second or third day patient became progressively weaker and died Jan. 16, 1915. Recorded in Group A.

CASE 93. Personal Case. Referred by Dr. C. A. Porter. Spindle cell sarcoma of clavicle. M. A., Jewish printer of 20. House No. 171355.

Oct. 12, 1910. Admitted with history of small lump noted 5 years previously above right clavicle, which has grown steadily in size. Rather pale youth with tumor size of small orange above the sternal half of right clavicle and apparently slightly attached to same. The mass is not tender, not adherent to skin, and of firm consistency.

Aug. 13, Dr. Porter shelled out a tumor which was adherent to clavicle. Anterior half of sternal end of clavicle chiselled off.

Pathological Report. (108-56) Dr. F. C. Kidner. Spindle cell sarcoma.

Feb. 9, 1911. Readmitted with tumor size of a walnut adherent to mid-clavicle. Excision of clavicle refused.

June 9, 1911. Readmitted. Mass now size of peach. June 10, Dr. Porter did a partial excision.

Pathological Report. (116-45) Dr. H. F. Hartwell. Fibro-sarcoma.

Nov. 14, 1911. Readmitted. Has had x-ray treatment for over three months. Despite this the tumor is now size of a large grapefruit, involving clavicle, tense, red and ulcerated. Nov. 18, interscapulothoracic amputation by Dr. Porter. The entire mass could not be removed. The apex of the lung already involved.

Dec. 10. Mixed toxin treatment started with injections into a mass about the size of an egg. Continued for one month without apparent effect. Maximum dose, 5 minims. Reactions moderate. Patient died April, 1912. Recorded in Group A.

CASE 94. Personal Case. Referred by Dr. Porter. Giant cell sarcoma of spine (recurrent). A. J. M., boy of 16. House Records, orthopedic, vol. xx, pp. 67; W. S. vol. 761, p. 161.

June 10, 1912. Admitted to hospital with following story: Fell three months ago, striking spine. Pain and tenderness have persisted in this region ever since and for two weeks numbness over external and anterior surface of right thigh with absolute loss of sensation.

Patient walks with slight instability, complaining of weakness of right knee, steps with great care, the slightest jar causing excruciating pain in lower dorsal region of spine, shooting up to head. Slight depression in region of tenth dorsal spine with swelling about the size of hand in posterior subcostal region. Both legs may be raised over about one-third normal arc, beyond which pain in the back and to right side of spine. Ankle clonus and Oppenheim sign on right. Area of analgesia over external as-

pect of right thigh just below trochanter. X-ray negative.

June 21, 1912. Nerve consultant (Dr. Baldwin) finds double ankle clonus and Oppenheim with disappearance of tactile and pain sense over right anterior crural distribution. Diagnosis, partial paresis of traumatic origin.

June 22, 1912. Swelling of back appeared fluctuant but aspirating needle revealed nothing.

June 26, 1912. Operation. Dr. Porter. Ether. Bluish colored, rather tense, fluctuant mass exposed beneath muscles of back; incised with escape of quantity of dirty liquid which was found to be encapsulated in rather definite sac with thickened broken-down tissue in walls. Vertebrae involved. Cured out and during operation Dr. Wright reported giant cell sarcoma. Transverse process removed, bone curetted, capsule trimmed as much as possible. Bleeding profuse. Cavity tightly packed. Patient put to bed in very poor condition but recuperated rapidly.

Pathological Report (126-126), Dr. Hartwell. Giant cell sarcoma. "Specimen consists of soft irregular pieces of tissue. Microscopical examination shows richly cellular tumor composed of spindle cells with numerous giant cells. The cells are very atypical and their richness varies in different areas of the tumor, some places being quite fibrous. There are scattered necrotic areas in the tumor tissue."

Treatment with mixed toxins started at once and continued until Jan. 29, 1913, seven months. Injections every other day and then twice a week. Maximum dose, 18 minims. Reactions usually severe. Seen 108 times. Injected 62 times. Early injections into belly, legs, and arms, and later into recurrence, which rapidly developed. Recurrence became in length $5\frac{1}{2}$ inches, in breadth $3\frac{1}{2}$ inches, in elevation 2 inches, with paresis of right leg. Despite violent reactions treatment persisted in. Tumor began sloughing in several areas and in January, 1913, no evidence of any mass or disturbance of sensation of limbs.

Since that time patient has reported every week or fortnight; has steadily gained in strength and weight; no evidence of recurrence by examination or x-rays.

April 27, 1914. Shown before the International Society of Surgery at Massachusetts General Hospital through the courtesy of Dr. Porter.

In June, 1914, a routine x-ray examination discovered a small mass apparently arising from lateral surface of spinous process of third lumbar vertebra. This mass was not evident by inspection or palpation and was producing no symptoms. The boy was apparently in excellent health. At operation Dr. Porter removed a circumscribed bone cyst.

Pathological Report. Bone cyst, no evidence of malignancy. This was a benign cyst, an inflammatory reaction. It still seems fair to claim that the toxins averted invalidism with paralysis (perhaps lingering death) from the early rapidly growing recurrence.

Patient examined every two weeks. Last seen Feb. 1, 1915 (2 years since toxins discontinued). Well developed and nourished. Good color. No subjective or objective evidence of recurrence. Scars soft and not adherent to structures beneath. Has worked many months as chauffeur. Recorded in Group F.

CASE 95. (Case No. 44, Personal communication, and *Annals of Surgery*, 1913, pp. 772-774). Giant

cell sarcoma of spine with paralysis of bladder, rectum and legs. 21, male. Swelling of lower back treated as Pott's disease with plaster case for several months. Patient grew steadily worse. The mass had become very protuberant, occupying the entire region from the 8th dorsal to 3d lumbar vertebrae and extending 3 inches either side of vertebral line. Toxin treatment for 3 months with intervals of rest. Maximum dose, 3 minims. Reactions marked. Progressive diminution in size of tumor with restoration of motor and sensory functions. Entirely well 7 or 8 months later. Subsequently married and has two children. Working regularly. Well without evidence of recurrence 12 years after toxins discontinued. Recorded in Group F.

CASE 96. (Table, Case No. 54.) Case of Drs. N. S. Hunting and J. J. Thomas. (B. M. and S. J., 1901, vol. cxlv, pp. 367-372.) Giant cell sarcoma of spine, involving ribs and compressing cord. 39, male. Exploratory operation revealed inoperable involvement of vertebrae.

Pathological Report. Giant cell sarcoma. Mixed toxins continued for 2 years with restoration of health. Well 5 years later, when died of acute lobar pneumonia. Recorded in Group F.

CASE 97. (Table, Case No. 63.) Giant cell sarcoma of sacrum. Case of Dr. Vradenburg. A woman. Operation for tumor of sacrum but impossible to eradicate disease.

Pathological Report. Giant cell sarcoma. Toxin treatment with entire disappearance of growth. Patient well $1\frac{1}{2}$ years later. Recorded in Group F.

CASE 98. (Case No. 10, p. 148). Giant cell sarcoma of superior maxilla. Case of Dr. J. C. Whitely, St. Louis, Mo. E. W., female. Operation unable to eradicate disease.

Pathological Report. Giant cell sarcoma. Toxin treatment. Maximum dose, 20 minims. Injections into tumor and buttocks. Tumor disappeared. No evidence of recurrence over 2 years later. Recorded in Group F.

CASE 99. (Case No. 46.) Giant cell sarcoma of superior maxilla. E. S., boy of 8. Had had 3 teeth and portion of alveolar process removed for growth of superior maxilla. Disease not eradicated.

Pathological Report. Giant cell sarcoma. Evident recurrence in about a year. Toxin treatment then started and continued 3 or 4 months. Reactions often severe. Well with no sign of recurrence $3\frac{1}{2}$ years later. Recorded in Group F.

CASE 100. (Case No. 28.) Giant cell osteosarcoma of inferior maxilla involving mouth. C. J. V. W., 17 male. A growth $4\frac{1}{2} \times 2\frac{1}{2}$ inches occupying entire lower portion of jaw extending back nearly to the angle on either side, and the floor of the mouth was filled nearly to the teeth level with growth. Outer portions of the growth chiselled away.

Pathological Report. (Dr. James Ewing.) "Giant cell osteosarcoma. It is not the ordinary encapsulated giant cell sarcoma of the jaw, or of the epulis type, but a tumor infiltrating in all directions and of rapid growth with large amount of new bone formation." Mixed toxins in two days and continued for 10 months. Injections into pectoral region and tumor. Reactions moderate. Dose 5 min-

ims. Tumor rapidly disappeared leaving no deformity. Death in 5 months from nephritis. Recorded in Group F.

CASE 101. (Case No. 25.) Recurrent giant cell sarcoma of ilium and sacrum. Mrs. X., 30. Two months after a fall a hard swelling appeared on ilium. At operation growth found originating in upper and outer portion of bone. Too extensive for radical removal.

Pathological Report. Giant cell sarcoma. Treatment with x-ray and radium for a number of months without benefit. At length confined to bed suffering great pain. Tumor involved whole outer aspect of ilium with 3 discharging sinuses. Toxin treatment for 5 months. Maximum dose, 3 minims. Size diminished, tumor softened. Incision made for drainage of cavity size of two fists. Toxins resumed for 11 months. Drainage reestablished. One year 2 months later in excellent condition without trace of recurrence. Recorded in Group F.

CASE 102. (Case No. 12, p. 149.) Giant cell sarcoma of femur. For several months a mass occupying outer aspect of thigh. Exploratory operation revealed a growth arising from middle of femur. Section removed.

Pathological Report. Giant cell sarcoma. Growth very rapid. Toxin treatment started. Maximum dose, 3 minims. Reactions severe. Marked sloughing of growth. After 4 months incision and curettage of necrotic material. Repeated 9 months later.

Pathological Report. No evidence of recurrence. Bony union of fracture. Patient well 6 years later. Recorded in Group F.

CASE 103. (Case No. 24.) Giant cell sarcoma of radius. M. F., 26, female. X-ray of fractured wrist disclosed pathological process of bone. Tumor curetted out.

Pathological Report. Giant cell sarcoma. Seventeen days later no evidence of union. Amputation refused. After 6 weeks of toxin treatment bony union occurred. Patient well 5 years, 5 months later. Recorded in Group F.

CASE 104. (Case No. 39.) Giant cell sarcoma of sternum. Miss C. Enucleation of growth at junction of manubrium and second rib.

Pathological Report. Giant cell sarcoma. Toxin treatment at once, and continued several weeks. Maximum dose, 3 minims. A recurrence had developed which involved entire width of sternum $2\frac{1}{2}$ inches long and elevated $1\frac{1}{2}$ inches. Skin ulcerated. Metastases involving glands of both sides of the neck. Toxins resumed and continued 4 weeks with no effect despite marked reactions. Despite progressive growth and severe hemorrhages, toxins continued. Finally neck swelling disappeared and pain ceased. Tumor was gradually sloughing when patient died of nephritis. This case is regarded by Coley as giant cell sarcoma with metastases. Recorded in Group E.

CASE 105. Personal Case. Referred by Dr. F. G. Smith of Somerville, Mass. Giant cell sarcoma of thigh, invading pelvis. J. W., school boy of 14. May 10, 1913, gives following history:

Feb. 20, fell on ice in such a manner that point of skate struck anterior surface of the left thigh. Three days later a swelling appeared, which pro-

gressively increased in size. April 10, Dr. Smith excised as much as possible. Bleeding profuse.

Pathological Report (Dr. W. F. Whitney). Giant cell sarcoma.

Recurrence soon appeared and there is now present a sloughing mass the size of a cantaloupe on the anterior surface of the upper thigh, extending beneath Poupart's ligament into the false pelvis. Toxin treatment at once started and continued $7\frac{1}{2}$ weeks with some disintegration of tumor at site of injection. Maximum dose, 12 minims. Dr. Smith states that during this time pulmonary and hepatic metastases undoubtedly occurred. The father states that boy had a peculiar limp long before skating accident. Died July 8, 1913. Recorded in Group B.

CASE 106. Personal Case. Referred by Dr. H. C. Low, of Boston. Giant cell sarcoma of ilium, sacrum and spine. J. A., Italian, 34. O. P. D. No. 207888. Seen March 24, 1913. Had been operated upon at another institution for growth in left sacro-iliac region.

Pathological Report. Giant cell sarcoma. There is now present a healed scar in this region slightly raised upon a mass $1\frac{1}{2} \times 1\frac{1}{2}$ inches, adherent to ilium. X-ray shows flattening of body of 4th and 5th lumbar vertebrae, with pathological process in ilium and sacrum.

March 31. Mixed toxin treatment started and continued 13 weeks. Reactions often severe. Maximum dose, 16 minims. No appreciable effect. X-ray treatment for 2 weeks without benefit. Patient died Aug. 20, 1913, with ulcerated, bleeding mass size of football. Recorded in Group A.

FASCIA AND MUSCLE.

CASE 107. (Case No. 7, p. 144.) Spindle cell sarcoma of calf. Case of Dr. McArthur of Chicago. 40, female. Radical excision of tumor arising from fascia of calf.

Pathological Report. Spindle cell sarcoma. Recurrence in 7 months size of one-half an egg. Patient several months' pregnant. Toxins for 12 weeks with disappearance of tumor. No recurrence 18 years later. Recorded in Group F.

CASE 108. (Table, Case No. 90.) Recurrent spindle cell sarcoma of knee. Case of Dr. C. S. Cole, New York City. Excision of growth arising from fascia about knee and involving periosteum.

Pathological Report. Spindle cell sarcoma. Recurrence in a few months. Second excision followed by recurrence 3 inches long. Toxins for 3 years with intervals of rest. Maximum dose, 30 minims. Patient in good health 10 years later. Recorded in Group F.

CASE 109. (Table, Case No. 56.) Spindle cell sarcoma of thigh. Case of Dr. H. P. Underset, Toronto, Canada. 22, male. Treatment for 2 or 3 months with mixed toxins for spindle cell sarcoma of thigh with entire disappearance. Patient well 2 years later. Recorded in Group F.

CASE 110. (Case No. 65.) Recurrent fibro-sarcoma of buttock and thigh. Mrs. S., 30. Large recurrent tumor of left thigh, involving muscles and fascia of thigh posteriorly. Mixed toxin treatment for 3 months. Injections into tumor with marked reactions. Five years later two small, hard, movable masses at site of former tumor. Excision.

Pathological Report. Fibrous tissue; no trace of

sarcoma. Well without recurrence 20 years after treatment stopped. Recorded in Group F.

CASE 111. (Case No. 81.) Recurrent small round cell sarcoma of back. N. J., boy of 8. Tumor of scapular region developed 2 weeks after a fall, and in a month became size of orange and fluctuant. Aspirated, but promptly refilled. On account of size it was impossible to remove completely. Practically disappeared under 4 months' x-ray treatment, but 3 weeks later recurred. Then mixed toxins started with disappearance of growth. In good health without recurrence 11 years 6 months later. Recorded in Group F.

CASE 112. (Case No. 79.) Recurrent spindle cell sarcoma of arm. Mrs. H. W., 25. A mass arising from fascia of upper arm 12 x 5 x 4 cm. (pathological report, fibro-sarcoma) quickly recurred. Fifteen months later there existed a definite swelling of two-thirds of the upper arm, involving $\frac{3}{4}$ of its circumference. Mixed toxin treatment still in progress at time of report (1 year 9 months). Injections into pectoral region and tumor. Reactions severe. Growth somewhat diminished in size. Recorded in Group E.

CASE 113. (Case No. 51.) Recurrent spindle cell sarcoma of palm. Mrs. M., 18. Excision of tumor of palm half size of hickory nut, followed quickly by recurrence. This also was excised.

Pathological Report. Spindle cell sarcoma. A second recurrence developed. Mixed toxins for 3 months. Maximum dose, 20 minims. Tumor disappeared but recurred in two years, resisting further toxin treatment. Amputation of arm was followed by general metastases and death in a few months. Recorded in Group C.

CASE 114. (Case No. 52.) Six times recurrent spindle cell sarcoma of palm. A. C., 21, female. The sixth recurrence of a spindle cell sarcoma of the palm was treated for 18 months with mixed toxins. The necrotic tumor tissue was then removed. Recurrence in 14 months. Forearm was amputated followed by metastases in brain. Recorded in Group C.

CASE 115. Personal Case. Referred by Dr. E. H. Risley, of Boston. Spindle cell sarcoma of thigh. M. O., Russian, 40. O. P. D., No. 53388.

Dec. 27, 1905. For 10 years has had a tumor growing in thigh. At present extends from just below trochanter almost to knee. Solid, not adherent to skin and apparently not adherent to bone. Mass excised by Dr. Hugh Williams on following day.

Pathological Report (Dr. W. F. Whitney). Round cell cystic sarcoma.

June 1, 1908. Recurrence at original site size of crab-apple. This and two small masses size of marbles removed by Dr. F. T. Murphy from muscle bed.

Pathological Report (Dr. W. F. Whitney). Small spindle cell sarcoma.

Oct. 19, 1909. Recurrence 10 x 4 inches slightly movable on bone. No evidence of extension into abdomen. Treated with mixed toxins from this day until June, 1910 (8 months). Injections every other day at first, then twice a week. Maximum dose, 10 minims. For 3 months tumor remained practically the same size, perhaps of slightly softer consistency, then grew rapidly, breaking down into a sloughing cauliflower growth. Hemorrhages frequent.

In June the tumor was nearly twice the size of a football. Died 2 days after amputation at hip.

Pathological Report (Dr. W. F. Whitney). Small spindle cell sarcoma. Recorded in Group B.

CASE 116. Personal Case. Referred by Dr. Wm. M. Conant. Mixed cell sarcoma of thigh. W. P. S., a clerk of 42. House Nos. 186608, 186632, 186737 and 187278.

Dec. 17, 1912. For several months has had soreness in groin necessitating use of a cane for 2 or 3 months, and two canes for about a month. Pain almost constant. Patient has osteitis deformans. Left hip can be flexed to about right angle. Other motions normal. Mass on anterior aspect of thigh extending from pubes one-third way down the thigh and posteriorly to tuberosity of ischium (about 4 x 5 inches), firm, apparently encapsulated, only slightly tender. Mass size of orange removed for examination.

Pathological Report (Dr. W. F. Whitney). Large mixed cell fibro-sarcoma.

Toxin treatment started Jan. 25, 1913, and continued in hospital until Feb. 13. Injections every other day. Reactions very severe. Maximum dose, 6 minims. No change in size of growth, but consistency distinctly softer. Patient then discharged to local physician, Dr. S. E. Donovan, of New Bedford, Mass., who continued treatment under my direction until March 11, 1913 (total of 7 weeks). Injections every second or third day. Maximum dose, 12 minims. At end of this time suffering intense. Mass about 6 x 6 x 5 inches, extending within pelvis and encroaching upon bladder and rectum. Patient died April 6, 1913. Recorded in Group A.

CASE 117. Personal Case. Referred by Dr. C. L. Scudder. Spindle cell sarcoma of thigh. B. H. C., 22, male.

May 21, 1914. Two years ago began to have pain in right thigh, and a freely movable mass of firm consistency, size of a fist developed. This was removed March, 1913, in another city. A recurrence developed which was removed in 3 months. A second recurrence developed and was excised Jan. 14, 1914.

Pathological Report (Dr. H. T. Karsner). Spindle cell sarcoma. The recurrence after this operation was extremely rapid, a small tumor being already present when the patient was discharged from the hospital. Now a tumor of the posterior aspect of right thigh size of a small cantaloupe movable, not attached to bone. Skin covering tense and bluish-red. X-ray examination (Dr. W. J. Dodd) shows no evidence of involvement of bone. On the lower abdomen there is a small mass, firm, freely movable, apparently entirely within subcutaneous tissue, the size of a walnut. This mass excised.

Pathological Report (Dr. H. T. Karsner). Mass 2 x 2 x 1 cm., covered by skin. Cut surface pallid, bulging, fleshy mass with a few small points of necrosis. Fibroma.

Toxin treatment of thigh tumor started May 26, 1914, and continued for 5 days. Maximum dose, 3 minims. Reactions moderate. Discharged to local physician, Dr. J. N. Roy, of Webster, Mass., for further treatment. Dr. Roy writes: Toxins continued 4 weeks, when tumor broke. Maximum dose, 5 minims. Reactions severe. Patient died July 21, 1914, of sudden, severe hemorrhage from large vessel involved in growth. No metastases were evident. Recorded in Group A.

CASE 118. Personal case. Referred by Dr. Hugh Williams. Round cell sarcoma of thigh. E. S., factory hand, 55. O. P. D., No. 148376. Seen March 7, 1910.

On May 25, 1906, had growth of 4 years' duration on anterior aspect of left thigh removed. It was thought to be a lipoma.

July 7, 1909. Another operation in same city for tumor in same region.

Pathological Report. Round cell sarcoma, with tendency to large rather than small cells.

For the past 5 months a recurrence has been growing and extending upwards into abdomen. The mass is now roughly 8 x 6 inches and lobulated. Toxin treatment for 3 weeks without appreciable effect. Patient then lost sight of. Recorded in Group A.

SKIN AND SUBCUTANEOUS TISSUE.

CASE 119. (Case No. 1, p. 136.) Melanotic sarcoma of neck. Case of Dr. Greenwood, Leeds, England. Recurrence $2\frac{1}{2} \times 3$ inches after excision of melanotic sarcoma. Eight days later mixed toxin treatment started and continued for 2 years 1 month (105 injections). Maximum dose, 15 minims. Growth disappeared in 5 months. Well 2 years after disappearance of mass. Recorded in Group F.

CASE 120. (Case No. 76.) Recurrent sarcoma of shoulder. H. B. M., 56, male. A benign tumor, which had existed for many years, began to grow rapidly and was excised.

Pathological Report. Spindle cell sarcoma. A small recurrence in 5 months. Mixed toxin treatment for several months. Patient well without evidence of recurrence 9 years later. Recorded in Group F.

CASE 121. (Case No. 61.) Three times recurrent round cell sarcoma of lip. M. S., girl of 5. Three excisions of growth of lip followed quickly by recurrence. Growth $1\frac{1}{2}$ inches long when toxin treatment started. Injections near tumor. Reactions mild. Tumor became firmer and smaller. Then excised.

Pathological Report. No trace of sarcoma. Treatment continued with intervals of rest for one year. Patient well without recurrence 16 years later. Recorded in Group F.

CASE 122. Personal Case. Referred by Dr. E. H. Risley. Melanotic sarcoma of back. F. H. F., iron worker, 35.

Under treatment two years, two months; seen 224 times; injected 195 times; maximum dose 53 minims. July 14, 1911, Dr. Homans excised, in the O. P. D., a growth of five weeks' duration arising from a pigmented mole over the right scapular region.

Pathological Report (117-73). "Specimen for examination consists of a rounded tumor 3 cm. in diameter which is sessile and dark purplish red with a surrounding oval-shaped piece of skin and subcutaneous tissue, varying in width from 1 to 2 cm. Section shows the center of the tumor infiltrating the subcutaneous structures. Microscopical examination shows a richly cellular tumor containing much brownish yellow pigment. The cells appear to have an alveolar arrangement. They are fairly large and spindle shaped with rather deeply staining nuclei. The tumor seems to be surrounded by a

tough layer of fibrous tissue but in places this fibrous tissue is very faint and the tumor appears to have gone beyond it. Melanotic sarcoma."

Oct. 26, 1911, Dr. Cobb excised, in the House, a recurrence to the outer side of old scar.

Pathological Report (1110-129), Dr. W. F. Whitney. "A piece of tissue from the shoulder measuring $6 \times 4\frac{1}{2}$ cm., in the midst of which was a coal black nodule $1\frac{1}{2}$ cm. in diameter. Microscopical examination of the nodule showed large cells, many of them containing a black pigment with a little intercellular substance between and irregularly infiltrating into the periphery. Melanotic sarcoma."

I saw patient fifteen days later with recurrence in second scar $2\frac{1}{2} \times 1\frac{1}{2}$ inches, and a palpable mass in the axilla the size of a pigeon's egg. Toxin treatment instituted. Within twelve days a mass the size of an English walnut had appeared in the same scar. The two masses became confluent but were entirely sloughed out in one month, leaving a soft thin scar. During this time, however, a recurrence appeared in the upper scar, which became in size $3\frac{1}{2} \times 2 \times 1$ inches. This whole mass was entirely sloughed out by Jan. 13, 1913. A pigmented mass appeared in the right pectoral region early in January, 1912. It ruptured in three weeks with local injections but increased in size until 3×2 inches. There were several erysipelatous attacks, when whole pectoral region would be red, hot, tense, and tender, with appearance of a second gland in the axilla and another in the neck. The latter became the size of a cherry, but entirely disappeared in one month. The axillary masses became the size of hen's and pigeon's eggs during these erysipelatous attacks, but within a month became decreased to size of pigeon's and sparrow's eggs and never became any larger until treatment was discontinued eleven months later, i.e. the upper axillary mass which was present when first seen (Nov. 10, 1911) was no larger and just as movable twenty-six months later when treatment was stopped (Jan. 28, 1914). The entire breast tumor (3×2 inches) sloughed out with continuous appearance of dark pigment by August, 1913, and never recurred. At this time patient was in excellent flesh with good appetite and no evidence of internal metastases. I was arranging with social service department for light employment. He then disappeared on a spree, returning in nineteen days haggard and weak. Treatment was resumed, but he never regained his former tolerance for toxins. The average dose for the last months was only 4.8 minims but the reactions were just as severe as he had experienced when taking 40 to 50 minims. New masses began to appear on abdomen, arms, breast, and back. He died February 26, 1914, with metastases in the spinal cord and abdomen. Recorded in Group D.

CASE 123. Personal Case. Referred by Dr. G. W. W. Brewster. Spindle cell sarcoma of shoulder. W. K. S., Canadian janitor of 44. House No. 185026.

Sept 18, 1912, appeared with profuse hemorrhages of tumor of right arm at insertion of deltoid. Six months ago he had scratched a mole in this region, and since then it had painlessly increased in size until now it is as large as an orange. Tumor firm, lobulated, not connected with bone, and ulcerated in several places. A number of glands size of walnut in axilla. Consensus of opinion after examination was against radical operation. Tumor mass was therefore excised with wide margin, and 4 days

later axilla entered, but growth had infiltrated walls of vessels and was obviously inoperable. A mass size of lemon removed.

Pathological Report (Dr. W. F. Whitney, 129-77). Spindle cell sarcoma.

One week later treatment with mixed toxins started and continued for 15 weeks. Injections every 2 or 3 days. Reactions very severe. Maximum dose, 16 minims. When toxins were started there was a mass over deltoid size of walnut and 2 masses in axilla about same size. During first 3 months of treatment all masses became softer and smaller; that on arm practically disappeared; those in axilla becoming about the size of beans. From this time patient troubled with much nausea and vomiting so that dose was necessarily reduced. Two weeks later mass evident in abdomen for first time. Grew rapidly. Toxins stopped. Mass apparently involved liver and either stomach or transverse colon, and within a month had extended from right flank to anterior axillary line on left and from costal margin to level of umbilicus. Recorded in Group D.

CASE 124. Personal Case. Referred by Dr. Beth Vincent. A multiple melanotic sarcomata. M. J. R., 38, female. Cigar maker. Hospital Records. E. S., vol. 688, p. 127; E. S., vol. 736, p. 153; W. S., vol. 727, p. 121.

June 4, 1910, reports with history of injury to left hand 18 months previously, followed by lesion with scab of dark brown color, which has persisted and has painlessly increased in size. Discolored, ulcerated, slightly raised area $1 \times 1\frac{1}{2}$ inches. Excised by Dr. Brooks with wide margin. Pathological examination by Dr. F. C. Kidner showed cells, very many with mitotic figures, occurring in mass of evidently infiltrated character and with pigment, intra and extra cellular.

Sept. 27, 1911. Recurrence size of a walnut, dark bluish color, and mass in axilla size of half an orange, firm, smooth, somewhat adherent, not fluctuant or tender. Dr. Cobb made attempt to dissect axilla. Tissue melanotic and very vascular. Growth on hand excised with wide margin. Patient then received daily x-ray treatment.

Three months later mixed toxins started. In meantime patient had developed tumor of left breast size of an egg. Mass in axilla size of English walnut. Two masses above umbilicus size of marbles. The latter were excised and microscopic examination showed melanotic sarcoma. Treatment continued for two months. Maximum dose, 16 minims. Reactions severe. Injections were given in various masses, either singly or collectively. Practically no change for 3 weeks, when blue-black subcutaneous masses were noticed in left neck, over left scapula and left acromion. Injections subsequently caused swelling and softening of growths, but new subcutaneous masses appeared from time to time and toxins omitted at end of two months. Recorded in Group D.

CASE 125. Personal Case. Referred by Dr. J. B. Hartwell. Multiple melanotic sarcomata. H. B. S., an English blacksmith of 25. O. P. D., No. 216268.

April 25, 1913. Reports with history of excision of small tumors from the left parotid region and left supra-orbital region in England in January, 1913. Three weeks ago recurrence appeared in parotid region, but other smaller masses had appeared on chest two months ago. At present a nod-

ular, non-tender tumor over left parotid size of English walnut; several small tumors in left supra-orbital region size of peas; two or three small pigmented nodules over left breast; and two small pigmented nodules on left arm. I advised against toxin treatment, but it was undertaken as a last hope and continued for 3 weeks. Although some tumors softened and sloughed out, new metastases continued to form. Recorded in Group D.

CASE 126. (Case No. 80.) Recurrent melanotic sarcoma of toe. Dr. D. Second toe amputated for malignant degeneration of naevus.

Pathological Report. Melanotic sarcoma. Several months later a recurrence in the groin, size of an egg, was excised. Pathological report, pigmented sarcoma. In two weeks a recurrence 2×3 inches. Mixed toxin treatment for six months. Tumor disappeared in a month. Seven months later patient died of metastases in brain. Recorded in Group D.

PAROTID.

CASE 127. (Case No. 56.) Recurrent round cell sarcoma of the parotid. E. S., 55, male. Removal of tumor of the parotid size of hen's egg attempted.

Pathological Report. Small round cell sarcoma. Quickly recurred. Toxin treatment for eight months. Maximum dose, 2 minims. Reactions moderate. In eight months tumor had disappeared. No recurrence five years, eight months later. Recorded in Group F.

CASE 128. (Case No. 63.) Recurrent spindle cell sarcoma of the parotid. W. L., 41, male. Three operations upon tumor of parotid, followed by recurrence.

Pathological Report. Spindle cell sarcoma. Toxin treatment started when tumor involved parotid and submaxillary region. Treatment for ten weeks with entire disappearance of growth. Six years later death from hemorrhage from gastric ulcer. No evidence of sarcoma. Recorded in Group F.

CASE 129. (Case No. 60.) Thrice recurrent mixed cell sarcoma of the parotid. Mrs. B., 25. Three operations upon the parotid followed by recurrence.

Pathological Report. Mixed cell sarcoma. Toxin treatment begun when tumor size of small egg, infiltrating entire gland. Treatment continued four months. Mass reduced in size to small movable nodule. This was excised. Pathological report, no trace of sarcoma. Patient well ten years later. Recorded in Group F.

CASE 130. (Table Case No. 10.) Small round cell sarcoma of the parotid. Case of Czerny. A tumor of the parotid had been removed, followed by inoperable recurrence size of fist.

Pathological Report. Round cell sarcoma. After eighteen injections, tumor resolved to a small mass, which was removed. Patient well one year later. Recorded in Group E.

CASE 131. Personal case. Referred by Drs. F. T. Murphy and Farrar Cobb. Large spindle cell sarcoma of the parotid (recurrent). G. P. C., an English butler of 34. House No. 178774.

Feb. 10, 1911, Dr. Murphy excised right parotid for mass 3 cm. in diameter, not adherent to the skin, and without glands in neck.

Pathological Report (112-31), Dr. Whitney. Fibrosarcoma. An elliptical piece of skin 6 x 3 cm., with a rather firm indurated tissue beneath, 2 cm. in thickness. Microscopical examination showed normal parotid tissue, in part of which was a firm rather fibrous new growth composed of fibrous tissue, in places very cellular with large elongated nuclei. This tissue infiltrated between the lobules of the gland itself.

About ten days after operation three injections of the mixed toxins on successive days with marked reaction. Maximum dose, 2 minims. Further treatment refused.

Seven months later Dr. Cobb operated for considerable recurrence causing paralysis of the right mouth and right eyelid.

Pathological Report (1110-77) Dr. Whitney. Spindle cell sarcoma. A piece of skin 6 x 3 cm., with a rounded ulcerated area about 2 cm., beneath which was an infiltrating growth. Microscopical examination of the growth showed it to lie in the subcutaneous tissue, and to be formed of interlacing bundles of rather large elongated spindle cells with small openings hollowed out in the tissue for blood vessels.

Two weeks later recurrence size of walnut. Mixed toxins resumed and continued for two months. Reactions marked. Maximum dose, 6 minims. Mass practically disappeared in six weeks, but within a week reappeared, and in another week was the size of half a crab apple, with a second mass the size of a walnut, close by. Patient died in two months. Recorded in Group C.

CASE 132. (Case No. 69.) Fibrosarcoma of the nerve sheath (anterior crural), with involvement of the muscle and glands. B. C. C., boy of six. Mass in the right groin appearing three days after injury with baseball; grew rapidly. Excision with recurrence in fortnight. Toxins for three or four months. Reactions moderate. Two years ten months later patient well without recurrence. Recorded in Group F.

CASE 133. (Table Case No. 91.) Recurrent melanotic sarcoma of the retina. Case of Dr. T. S. McDermott of New Haven. An attempt at removal was followed by recurrence involving the orbit. This was hopelessly inoperable.

Pathological Report. Melanotic sarcoma. Toxins for three months with disappearance of growth. Three and a half years later, however, metastases in liver, and death. Recorded in Group D.

CASE 134. Personal Case. Referred by Dr. Balch. Round cell sarcoma of the spermatic cord involving the abdominal muscles. S. G., Italian of 40. W. S., vol. 675, p. 305. Sept. 8, 1910. Admitted with history of pain and mass in left groin after heavy lifting five months ago. This mass had increased in size until it now extends from the internal ring to base of scrotum. Sept. 9, Dr. Balch performed a left orchidectomy with excision of portion of lower abdominal wall for infiltrating tumor.

Pathological Report (109-32), Dr. F. C. Kidner. Round cell sarcoma.

Toxin treatment started in four days and continued one month. Despite severe reactions a recurrence quickly appeared and grew rapidly until size of a large pear when toxins discontinued. Recorded in Group A.

ERRATUM AND ADDENDA.

Under Conclusions (page 335) the last line of the sixth paragraph should read, An equal division of round and spindle cell, instead of "An equal division of round and small cell."

CASE 1 (page 336) was seen March 18, 1915. There was no objective or subjective evidence of recurrence (3 years, 11 months since toxins discontinued).

CASE 3 (page 337) has written (March 1, 1915) since the paper went to press that there is no evidence of the old trouble and that she is feeling perfectly well. (2 years, 11 months since toxins discontinued).

CASE 94 (page 442) was examined March 16, 1915. There was no objective or subjective evidence of recurrence (2 years, 1 month since toxins discontinued).

Medical Progress.

EIGHTH REPORT OF PROGRESS IN ORTHOPAEDIC SURGERY.*

BY ROBERT B. OSGOOD, M.D.; ROBERT SOUTTER, M.D.;
HERMANN BUCHOLZ, M.D.; HARRY C. LOW, M.D.;
AND MURRAY S. DANFORTH, M.D., BOSTON.

TUBERCULOSIS.

DaCosta¹, after a thorough discussion of the subject, concludes that the occurrence of traumatic tuberculosis is a necessary deduction from acknowledged facts. He does not believe that the dogmatic decision which has long been a precedent in court, that traumatism has nothing to do with the determination of tuberculosis, can be upheld.

[Ed. Note.—We called attention in the Fifth Report of Progress in Orthopaedic Surgery to the investigations of Wilson and Rosenberger², in which nearly the same conclusions were reached. The experience of the editors is also in general accord with this view. It is obvious that tuberculosis does not exist unless tubercle bacilli are present and that traumatism does not produce tubercle bacilli. Nevertheless, their very common existence in the body, without giving rise to symptoms, is well known, and in the light of these investigations it seems probable that trauma may be the direct exciting cause of their rapid development at the seat of the injury into a definite tuberculous lesion.]

Froelich³ has given much consideration to the tuberculous processes in infants and has pointed out certain special features which these infantile cases present. 1. A tendency to hypertrophy in both bone and joint affections with an early opening and a short sinus period. 2. The frequent involvement of the shaft of the bone in contradistinction to the usual epiphyseal lesion of later life. 3. The tendency to dislocation, especially in the diseases of the hip joint.

* This report is based on a review of 303 articles selected from about 500 titles having to do with orthopaedic surgery, appearing between March and August, 1914. References are given to only such articles as have been selected for note and comment.

4. The occurrence of an acute form most common in the knee and elbow, running a rapid course, healing soon after evacuation, and leaving little stiffness. 5. The common existence of multiple bone foci. 6. The predilection of the process for the testicle and the immunity of the prostate. In making the diagnosis syphilis and a staphylococcus infection must be carefully excluded. The mortality he considers to be about ten per cent. The process in the viscera and peritoneum runs the same grave course as in older children, but in other locations the tendency to spontaneous recovery is very noticeable. This should lead to much more conservative surgical treatment than in older children.

Huntington⁴ is still sceptical concerning the permanent cure of bone tuberculosis by rest, fixation, traction and general systemic treatment. He does not believe in the efficiency of conservatism and believes that most bone foci can be easily reached. He reports further cases in which following MacNamara he has tunnelled the neck of the femur through the great trochanter to reach foci in the head of the bone. He thinks epiphyseal lines are often invaded by the disease but need rarely be considered. The cavity may be treated with pure carbolic acid and alcohol, phenol, camphor, Beck's paste, etc.

[Ed. Note.—With the belief which Huntington seems to hold that tuberculosis of the joints is usually best treated by operation designed to remove the tuberculous disease, the editors cannot agree. Localized bony foci not involving epiphyses or epiphyseal lines may perhaps well be so treated in children. In adults surgical procedures designed to prevent the spread of the disease and bring about a bony ankylosis may be often advisable. Rogers' experiments on young dogs have shown that very decided disturbances of growth may result from tunnelling operations through the diaphysis into the epiphysis, and results from purely conservative measures coupled, as in Rollier's clinic, with heliotherapy leave little to be desired. The men who have had largest and longest experience with both radical surgical and conservative treatment in children are the ones who most strongly advocate rest, fixation, and general systemic treatment and oppose surgical procedures designed to radically remove foci of disease involving the joint structures.]

Vulpinus⁵ considers his results from the Albee operation of bone graft into the spinous processes in tuberculosis of the spine to have been very satisfactory. He emphasizes the eminent pain reducing effect of the operation and the increased activity of the children. He insists upon prolonged rest after the operation and applies a brace.

Jacobs⁶ advocates the Albee operation in cases where conservative treatment has failed or the element of time is an important factor, believing that the method represents a great advance in the treatment of Pott's disease except in early

childhood. He believes that a callus firm enough to stand the great longitudinal sliding strain in these bone grafts needs many months for its development. He thinks fixation in a jacket or brace should be maintained for six months or more.

Beecherle⁷ reports a case of fibroepithelioid tumor of the tendon sheaths of the hand. It is of interest in calling attention to the fact that tubercle bacilli may cause an atypical formation resembling a neoplasm.

ARTHRITIS.

Rosenow⁸ has failed in only three out of thirty-eight cases of "arthritis deformans" to isolate organisms from glands draining the affected joints. In fourteen cases he found streptococci, in nine a peculiar staphylococcus-like organism at first completely or partially anaerobic, in nine the bacillus Welchii, in three staphylococci, in one the bacillus mucosus, in one the gonococcus. The author states that "There is often great sensitiveness of the patient to injection of killed organisms (autogenous vaccines) isolated from these glands and marked improvement may follow the injection. These facts in conjunction with the affinity of the organism for joints and muscles of dogs and rabbits after intravenous injections would seem to leave little doubt that the bacteria found in the glands draining the joints in arthritis deformans are the actual cause of the disease." He attributes part of the joint changes to the shutting off of the blood supply of the joints by the plugging of the vessels from endothelial proliferation induced by the organism. This possibly is further suggested by the experiments of Axhausen,⁹ who produced the gross and microscopic changes peculiar to arthritis deformans by ligating the blood vessels supplying the structures of certain joints in dogs, and by the later work of von Manteuffel,¹⁰ who, following the work of Rudnicki on the soft parts, produced artificial sclerosis of the vessels and changes in the articular ends of the bones by freezing and congestion. In these experiments of von Manteuffel there was finally complete disappearance of the cartilage and of the entire joint with connective tissue ankylosis of the two bones.

[Ed. Note. From the Editors' point of view it is unfortunate that the types of chronic arthritis are not more accurately differentiated by Rosenow. We suppose that he refers to the toxemic or infectious types and not to the senile hypertrophic types of arthritis deformans, or as Nichols and Richardson call them, the degenerative non-ankylosing types. In these latter we should not expect bacteria to be found as the causative agents, though the diminished blood supply from lime deposit in the vessel walls may well exert an influence on the joint changes.]

Hastings,¹¹ realizing that cultures from the blood, joints, and possible foci cannot be made in

all of a series of cases and that no one of these would be considered as a determining factor in all cases, has chosen the complement fixation test as a means of determining the bacterial cause of the "chronic infective deforming arthritis." Hastings' observations cover some 75 cases. Forty per cent. of these reacted only to the complement fixation test for streptococcus viridens, in others the gonococcus, Wassermann, and other fixation tests were positive. He considers it very rare that the manifestations of "arthritis deformans" are due to the gonococcus.

Thalhimer and Rothschild¹² produced an arthritis in half the rabbits they injected with streptococcus mitis. In character this arthritis was similar to the process caused by the micrococcus rheumaticus. They think that it is evident that an arthritis can be produced experimentally by blood inoculations of various streptococci and micrococci of the less virulent (non-pyogenic) group, but that evidence is still lacking that any distinct variety or species of streptococci is the specific cause of arthritis, at least in rabbits.

Moore¹³ has studied the action of vaccines and concentrated antistreptococcus serum in experimental streptococcal arthritis in rabbits, and while there are yet too few cases for any conclusions, the work is suggestive. Moore's experiments were stimulated by the fact that antistreptococcus serum had not been altogether satisfactory and he desired to find out whether in the presence of certain antibodies the serum was of low potency, hence the trial of the concentrated sera. Concentrated serum does not appear to have any effect on acute arthritis, though it may act as a prophylactic against further experimental infection and it may produce an immunity of from one to two months.

Greeley¹⁴ writes rather positively concerning the cause, and very optimistically concerning the treatment of "chronic rheumatism." He considers that it is experimentally proven that the introduction into an animal of a parasitic organism whose virulence is nearly balanced with the host's power of resistance frequently results in the establishment of chronic foci of infection in locations not reached by the blood plasma and leucocytes in full concentration. He believes that pathologically the lesions of chronic rheumatism occur in this way where the circulation is at a minimum in the arteries in the ends of the bones. He considers that the results in fifty-three cases which he has treated by means of autogenous vaccines have been satisfactory. He obtained the vaccine five times from the blood, fifteen times from the urine, and thirty-three times from the throat, the latter source he considers to be always satisfactory except in gonococcal infection. The vaccines should be autogenous and should never be given in acute cases. The size of his dose (which does not seem to be necessarily exact) is from one hundred million to one billion, not oftener than once in eight to ten days. He believes implicitly in the future of this treatment.

[Ed. Note.—We should like to share in the optimism of Dr. Greeley, but a considerable observation of the results obtained from the use of autogenous vaccines, mainly derived from the throat, does not lead us to believe that the problem at present is either simple or sure of solution by this method. Not only have we failed to obtain any marked improvement in many cases in which we believe the vaccines to have been administered with knowledge and with judgment, but in certain cases it has been evident that the treatment had been too long continued until the patient did not react and seemed more susceptible to fatigue and other infection.]

Brackets's¹⁵ paper on arthritis associated with lesions of the genito-urinary tract is based on a wide experience, and his analysis of types and treatment seems to us clear and sound. He believes the responsible organism to be either the gonococcus or the colon bacillus. The gonococcal infections are of two types. One, usually monoarticular, in which there is a direct bacterial invasion of the joint characterized by an arthritis of sudden appearance, giving evidence of very acute synovial inflammatory involvement. This process later shows an inherent tendency to marked contractures with strong adhesions and destruction of articular cartilage. In the acute stage the organism may at times be recovered from the joint. The second type is polyarticular and of a mildly inflammatory nature, slowly damaging the joints from toxic infection. This type may develop with an entirely quiescent external urethral condition. Arthritis associated with a colon bacillus infection of the genito-urinary tract is of a severe persistent type of multiple distribution, having a predilection for the larger joints and frequently for the spine. The treatment in the acute type of Neisser infection should be directed toward the urethral focus and also toward the joint condition. This later requires often radical treatment; in the early stages hot salt solution lavage through a small incision and a subsequent drainage. The later stages of these cases offer ideal conditions for inflation with 4% iodoform oil. (See article on Iodoform Treatment of Ankylosed Joints, BOSTON MEDICAL AND SURGICAL JOURNAL, June 4, 1914). In the toxic types of gonorrheal infection and in the arthritis of colon bacillus origin, the treatment after search for and elimination of the focus should consist of measures aiding the absorption of exudates, improving nutrition, and favoring the return of motion.

Manning and Fassett¹⁶ report a case showing a typical clinical picture of Still's disease with small palpable glands in the cervical, axillary, and inguinal regions, in which carious teeth and a chronic otitis media were apparently the causes of the arthritis. Under general hygiene and the removal of the supposed sources of infection the condition rapidly improved. The case seems to be one more proof that Still's disease is an infectious or toxic arthritis.

O'Malley¹⁷ draws an interesting analogy be-

between otosclerosis and arthritis deformans, meaning evidently the osteoarthritic, hypertrophic, or degenerative type. He reaches the conclusion that they are due to the same cause. "The essential factor underlying the morbid changes in both diseases) is a chemical one affecting the nutritive stability of developing and fully developed bone and cartilage comparable to the rachitic phenomena, but how these chemical disturbances are actually initiated it is at present not possible to explain. Otosclerosis is osteoarthritis of the stapedio-vestibular articulation and of the bony labyrinth capsule."

[Ed. Note. We are interested in these conclusions of O'Mallay, working in another specialty. From a clinical point of view at least the hypertrophic or degenerative type of deforming arthritis occurring late in life has seemed to be best explained on a chemical rather than a bacterial theory of cause.]

We wish to mention a dissertation of Golant¹⁸ on ankylosis of the spinal column. This is based on a careful study of nine cases from von Bechterew's clinic, two of which died and were subjected to a careful macroscopic and microscopic study of the spinal column and the central nervous system. There are 26 illustrations and a bibliography of 221 titles. His most important conclusion seems to be that in certain cases symptoms of the involvement of the central nervous system predominate and at autopsy there are found both chronic meningitis and degenerative changes in the substance of the spinal cord and spinal roots which justified the separation of these cases into a special type known as Bechterew's disease.

Although Perthes¹⁹ has described the typical clinical picture of the condition, osteoarthritis deformans juvenilis, Drehmann²⁰ wishes to limit more strictly the use of the name by excluding all those cases showing any inflammatory signs or any tendency to contracture. The occurrence is in children between five and ten years of age and is usually limited to one hip. The first symptom is limping without much pain and with free motions except abduction. There is no outward rotation as in coxa vara,—in fact, sometimes slight inward rotation causing the trochanter to appear in the x-ray as slightly enlarged. There is as a rule no shortening. After several years the limp frequently improved and except for a more or less pronounced limitation of abduction there may be a perfect restoration of function. Perthes' pathological examination of a case showed intact cartilage, the head flattened, and its centre depressed. Drehmann, studying the course of cases by radiographs, has observed an atrophic area in the neck just beneath the epiphyseal line, which changed its form under pressure of the head. The primary change he believes to be in the neck, the head of the bone adapting itself to this. He considers the disease to be analogous to coxa vara adolescentium, but in this epiphyseal form the head shifts in the varus direction, *i.e.* downwards,

while in the osteoarthritis deformans juvenilis of Perthes the shifting of the head over the neck is in the valgus direction, *i.e.* upwards. Drehmann therefore proposes the name coxa valga epiphysaria. The cause of the condition is still obscure.

The paper of O'Reilly²¹ on Joint Syphilis is worthy of comment. It represents a study of 26 cases which show the necessity of careful history taking and both clinical and laboratory examinations in all cases of arthritis. O'Reilly found that 10% of the cases of arthritis in the clinic of Washington University Hospital in St. Louis were syphilitic in origin, and among these cases were many of supposed tuberculosis, osteoarthritis, and infectious arthritis. O'Reilly believes that the Wassermann reaction should be done in all cases of arthritis.

D. W. C. Jones²² suggests a new etiological classification for arthritis in line with that accepted for disorders of other parts of the body. This seems to the Editors to be simple, inclusive, and based on clinical knowledge. While it is perhaps no better than certain other classifications, it is added evidence of the more general acceptance of the fact of the existence of definite types of chronic and acute joint disease and of the importance of their recognition. The suggested classification is as follows: 1. Senility—Osteoarthritis. 2. Metabolic Toxemia—Gout. 3. Infectious Toxemia—Acute Rheumatism, Rheumatic Arthritis. 4. Focal Infection—Gonorrheal, Pneumococcal. 5. Granulomatous Infection—Tuberculous, Syphilitic. 6. Neoplasms (Rare). 7. Trauma—Traumatic Synovitis, Hemophilic Joints.

PARALYSIS.

Poliomyelitis—Obstetrical.

Poliomyelitis.—If their observations are verified, Saunders, Meisenbach, and Wisdom²³ have made a very important contribution to the epidemiology of Poliomyelitis. With others they have been impressed by the variety of diseases associated with paralysis which affect farm animals, children, hogs, dogs, pigeons, and others. They searched, therefore, for a larval fly which when ingested might produce these conditions. The common green backed fly (*Lucilia Caesar*) seemed to fulfill these requirements, depositing freely its eggs in the carcasses of animals. Upon these dead bodies chickens often feed. Experimentally they produced in monkeys and other animals a characteristic poliomyelitis by inoculating them with larvae obtained from the bodies of dead fowl. The course of the disease and the microscopic lesions were typical. They transmitted the disease by inoculations with emulsions of the spinal cord. They were able to produce the disease in hogs, chickens, rabbits, and guinea pigs by both inoculations and ingestions of the infected larvae. These larvae may be left by the fly on any piece of food upon which she rests and

the authors plead strongly for the extermination of the fly, the isolation of all sick animals, the covering of manure piles, and the screening of kitchens.

Francis²⁴ reports unsuccessful attempts to transmit poliomyelitis by the bite of the blood sucking cattle fly (*Lyperosia irritans*). Shaved monkeys, sick with poliomyelitis, were bitten by these flies for six days. The flies were then allowed to bite four well monkeys for six days. The disease was not transmitted in any instance.

Flexner, Clark, and Amoss²⁵ state that a strain of the virus of poliomyelitis transmitted through monkeys for four years showed three distinct stages of virulence each covering different periods of time. They suggest that this phenomenon of the cycles of change in the virulence may be correlated to the wave-like fluctuations in epidemics.

Robert Jones²⁶ has reviewed in his characteristically helpful manner the surgical treatment of poliomyelitis, emphasizing the important principles which should form the basis for all orthopaedic treatment. Perhaps the most essential factor is the possession by surgeon and patient of "boundless spirit and buoyant enthusiasm." In his description of his operations for correction of position and restoration of function in the paralyzed member by tendon transplantations, etc., he is most explicit, and one feels that no detail of technic is too small to be most carefully carried out.

Artificial ligaments and tendon fixations, especially the latter, he believes to be of great usefulness, not only because they improve function by maintaining a better position, but also because they allow over-stretched but not completely paralyzed muscles to regain some degree of power.

[Ed. Note.—Those who have had the opportunity to observe the results obtained by Mr. Jones by the use of the surgical measures he advocates need no better proof of the soundness of the principles which have dictated his exquisite technic.]

Netter²⁷, on the principle that the serum of persons who have had an attack of poliomyelitis might contain antibodies capable of exerting an effect upon the virus present in an acute attack, has made intraspinal injections of serum obtained from old cases of poliomyelitis. His most striking case was that of a man of 34 who was apparently recovering from a severe, acute poliomyelitis, when on the eighth day his legs became paralyzed. There was retention of urine and disturbance of sensibility extending up to the costal arch. On the ninth day, with the paralysis apparently progressing, Netter injected into the spinal canal 7 c.c. of serum obtained from a person who had had poliomyelitis seven years previously. By this time the anesthesia extended to the nipples, but on the evening of the day on which the injection was given the patient could "feel his toes." He was given ten injections in eleven days, the amount totalling 66 c.c., the

serum being obtained from eight different persons. Netter had applied this treatment in four other cases, but with such timid technic and with so few injections that although he says there was marked benefit apparent each time, yet some paralysis was left or the patients succumbed sooner or later.

Fraser²⁸ has reported the results of his careful clinical observation of ninety cases of acute epidemic poliomyelitis. He is doubtful of the great value of electricity. He is convinced of the value of early gentle massage and passive exercises, and later active and resistive exercises. We believe he emphasizes an important point when he speaks of the desirability of avoiding heavy braces and of persistent attempts to get the children to walk without any apparatus except that to prevent deformity.

Obstetrical Paralysis. Peltsohn²⁹, after a careful Roentgenological examination of eleven shoulders in ten cases of obstetrical paralysis, has found an injury to the upper epiphysis in nine. Of these nine, three were true paralyzes and six pseudo-paralyzes. In all cases, therefore, of pseudo-paralysis a definite separation was seen. Peltsohn believes that a real separation of the epiphysis is much more frequent than Lange considers it to be. The treatment in infants consists in fixing the arm in a position of elevation, abduction, and outward rotation, provided the epiphysis is united. If the epiphysis is still loose a position, of course, must at first be maintained which is most favorable to union. In older children manipulation may be helpful, but with a fixed distortion of the shoulder osteotomy below the insertion of the tendons of the pectoralis major seems to Peltsohn to be the best procedure.

(To be continued.)

Reports of Societies

SECTION OF GENERAL INFORMATION OF THE COLLEGE OF PHYSICIANS OF PHILADELPHIA.

MEETING OF MONDAY, DECEMBER 14, 1914, AT 8.15 P.M.
DR. JAMES E. TALLEY in the Chair.

RECENT CHANGES IN OUR CONCEPT OF THE ACTION OF DIGITALIS.

DR. H. C. WOOD, JR.: Many of the older theories concerning the effects of digitalis are drawn from experiments in which toxic doses were employed. When given in physiological doses, digitalis does not increase the blood pressure in either man or the lower animal. It is probable, however, that there is some constriction of the blood vessels, as is shown by the fact that when the slowing of the pulse is prevented the pressure is increased, and it is probable also that the diuretic effect is due to changes in the caliber of the vessels. The slowing of the

pulse, which is the most constant effect of digitalis, is in healthy individuals purely inhibitory. Stimulation of the vagus may produce heart block and other irregularities of rhythm. The slowing of the pulse is completely abolished by large doses of atropine. The muscular tone is not demonstrably affected after small doses, although it is possible that the largest therapeutic doses may increase it. The cardiac contractions are, however, enlarged. The effects in disease are often very different from those in health. In fever the vagus appears to be less than normally irritable, and digitalis does not slow the pulse. In chronic endocarditis the effects are different according to whether the rhythm is normal or there is auricular fibrillation. In the latter condition it will generally produce very great slowing of the pulse. It is impossible from the present data to draw positive conclusions as to the mechanism of its action in this condition, but it is probably partly due to stimulation of inhibition and partly to diminished ventricular irritability, the result of better nutrition. In cases of endocarditis with normal rhythm its effects are often much less marked. It is a mistake to give digitalis in all cases until the manifestation of toxic effect. Some conditions require larger doses to have any action, while others may be injured by full doses, but benefited by small ones.

CLINICAL AND ELECTROCARDIOGRAPHIC STUDIES OF THE ACTION OF DIGITALIS.

ALFRED B. COHN, M. D., of the Hospital of the Rockefeller Institute for Medical Research: The investigations reported were made in patients having an early rather than an advanced stage of heart disease. The mechanism of their hearts was normal, they had no edema, and their blood pressure was within normal limits. The most important alteration we have been taught to look for is in the heart rate. The reduction in the rate of the heart is an effect of digitalis upon which we rely, but one which we have not found constant in the type of case we are considering. We have been led to conclude from our observations that digitalis slows the sinus rhythm only in the group or hypodynamic hearts, and, that to produce slowing is not a function of digitalis in therapeutic doses. An effect on conduction may be set down as a usual effect of giving the drug, apart from specific preëxisting injury. We have noticed delayed conduction within 48 hours after the administration of the drug had been started. In many instances the auriculo-ventricular interval gradually lengthened during the succeeding three to five days until partial heart block occurred. In some cases, however, block occurs with extreme abruptness. One arrhythmia, practically unknown, the results of giving digitalis, is one in which none of the auricular beats are blocked. The auricles and ventricles continue to beat almost at the same time, but there is incomplete coördination between them. Another new sign in the electrocardiogram is an alteration in the size, shape and direction in the T-wave. The first change noted after the administration of digitalis is usually a diminution of the height of this wave, usually in the third Lead first and later in the second. The change may be noticed as early as 24 hours, and at the end of 48 hours the wave may have become isoelectric, or it may become diphasic. In some electrocardiograms the T-wave for pathological reasons is pointed downward. If

digitalis is given, the direction of the T-wave during the action of the drug is pointed upward. While the causative factors in the change of the T-wave cannot be precisely explained, the inference is that there is an alteration in the contractile substance of the heart muscle. Two criteria appear then in electrocardiograms to indicate surely the fact that digitalis is acting on the heart; the first in the slight but definite lengthening in conduction; the second, the very curious alteration in the T-wave. Electrocardiographic evidence can be supplied to show that digitalis has an action during fever of a nature precisely similar to that already described in non-febrile patients. Possibly, as an aid to contraction, much can be gained from the use of digitalis, but the expectation of obtaining an action on heart rate must be abandoned. There is, however, a group of febrile cases in which digitalis acts efficiently on rate. These in our experience have been patients showing auricular fibrillation or auricular flutter. Another topic long a subject of conflict is the relation of digitalis action to blood pressure. In the cases we have studied no alteration in pressure was found. Vascular effects, however, aside from changes in pressure, may be produced, and the untoward or beneficial nature of these require consideration. The relation of digitalis to the excretion of urine also was discussed. In the group of patients under consideration no increase in diuresis takes place. In patients having edema, other factors are involved. That a specific effect on urinary output does not occur as the result of giving digitalis, in the patients under discussion, has an important bearing on the drug's action in edema. In connection with the mechanism of the action of digitalis two possibilities have been much discussed; an action on the inhibitory mechanism and one on the heart muscle itself. Our studies lead us to believe that both views are partly right. Insofar as atropin may be taken to be a drug acting especially on the ends of the vagi, a release of the heart from a phase of digitalis action by its use indicates a nerve action of digitalis. Insofar as digitalis has other effects which atropin does not release its effect on the T-wave, it may be inferred that it has an action directed more especially to muscle. Both effects can be observed at the same time.

Book Reviews.

Forty-Sixth Annual Report of the Secretary of State on the Registration of Births and Deaths, Marriages and Divorces in Michigan for the Year 1912. Lansing, Mich.: State Printers. 1914.

This forty-sixth annual registration report records the vital statistics of the State of Michigan for the year 1912. During this period the birth-rate of the state was 32.9, the death-rate 13.4, the marriage rate 21.8, and the divorce rate 2.7. There was a total increase of 3,781 births, 797 deaths and 1835 marriages over 1911.

THE BOSTON Medical and Surgical Journal

An independently owned Journal of Medicine and Surgery, published weekly, under the direction of the Editors and an Advisory Committee, by the BOSTON MEDICAL AND SURGICAL JOURNAL SOCIETY, INC.

THURSDAY, MARCH 25, 1915.

EDITORS.

ROBERT M. GREEN, M.D., *Editor-in-Chief.*
WALTER L. BURRAGE, M.D. } *For the Massachusetts Medical Society.*
FREDERICK T. LORD, M.D. }

COMMITTEE OF CONSULTING EDITORS.

WALTER B. CANNON, M.D.	ALLAN J. McLAUGHLIN, M.D.
HARVEY CUSHING, M.D.	ROBERT B. OSGOOD, M.D.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States. \$6.56 per year for all foreign countries belonging to the Postal Union.

The editor will be in the editorial office daily, except Wednesday and Sunday, from twelve to one-thirty p. m.

Papers for publication and all other communications for the Editorial Department should be addressed to the Editor, 126 Massachusetts Ave., Boston. Notices and other material for the editorial pages must be received not later than noon on the Saturday preceding the date of publication. Orders for reprints must be returned in writing to the printer with the galley proof of papers. The Journal will furnish the first one hundred reprints for half the cost price.

All letters containing business communications, or referring to the publication, subscription, or advertising department of the Journal, should be addressed to

ERNEST GREGORY, *Manager.*

126 Massachusetts Ave., Corner Boylston St., Boston, Massachusetts.

THE LABOR CLEAN MILK BILL, AGAIN.

A CORRESPONDENT of the JOURNAL of March 11 criticizes the editorial of Feb. 25, favoring the so-called Labor Clean Milk Bill, and by inference the position of the Massachusetts Medical Society, which through its legislative committee, has appeared in advocacy of this bill before the Committee on Public Health. In so doing, the Society has ranged itself alongside the Milk and Baby Hygiene Association, the Consumers' League, and the Antituberculosis League. It also has been glad to find itself in accord in this instance with the Federation of Labor, which organization it has sometimes been pained and surprised to find opposed to measures of public health, as, for instance, smallpox vaccination.

The measure this year introduced by the Federation of Labor is, as was stated, simple and

direct, and its advocates have clearly shown that no class of the community has so vital a stake in public health measures as the wage-earners. When, as now, the Labor party takes a wise and moderate position, it behooves the good citizen to avail himself of their certainly powerful aid.

The gist of the correspondent's opposition to the bill appears to be that it is unnecessary, as local boards of health have power to handle the situation. In a community whose health administration is as efficient as Canton's appears to be, a community drawing its milk supply wholly from its own confines or vicinity, and especially *inside the state limits*, this may be true. But the best local board, unless given abundant money to go and examine out-of-state sources, as is done in Massachusetts by Boston only, would be powerless to protect its inhabitants. A possible factor in the low estate of the milk industry in Massachusetts is the severer standard exacted of our own producers than that required of out-of-state farmers. This bill bears equally and impartially upon both.

Moreover, the scrutiny of out-of-state sources by separate municipalities would be very uneconomical. A bill has been reported giving the State Board an appropriation for this purpose, and should this be carried, the work of health boards, local or state, in penalizing filthy conditions of milk handling, would be much facilitated.

But, unfortunately, not all local boards are as wide awake and active as that of Canton. Many towns have no milk inspection whatever. In others, local politics, the overshadowing influence of some local magnate, and the hesitation of the local authority to offend a good neighbor, weaken the endeavor and efficiency of the local board. It is hardly adequate to say that in case of a feeble health board the people "ought to" rise up, sweep it away, and elect an active board. The torpor of the board only reflects the indifference of that community. In such cases, and in those only, the State Board should be empowered to step in, free from any local intimidation, and see that the people are protected against the consequences of their own neglect.

CHARLES F. WITHINGTON, M.D.,
President of The Massachusetts Medical Society.

FACTORS IN THE DURATION OF PULMONARY TUBERCULOSIS

IN another column of this issue of the JOURNAL we publish an important article by Dr. Crane on "The Diagnosis and Treatment of Pulmonary Tuberculosis." Now that a diagnosis of tuberculosis is no longer tantamount to a death sentence, the question of prognosis and duration in a given individual becomes most pertinent. In no other disease has this question quite the same significance, because this disease involves a personal incapacity and dependence over a long period of time as well as involving the undoubtedly large element of danger as a constant focus of infection unless the patient is maintained under strict surveillance, or unless he is himself sufficiently educated in the hygiene of tuberculosis so that he needs no surveillance.

While it is true that this question of prognosis and duration cannot be determined as easily or as definitely as in the rather few self-limiting diseases, yet certain conditions peculiar to this disease when accorded their proper values are of positive aid—namely, racial and hereditary predispositions or immunity, previous physical condition, occupation and environment, and the extent of the lesion in the lung at the time the patient first came under notice.

Although it is not scientific to speak of tuberculosis as racial or hereditary in its selection, yet practically speaking heredity and race seem to be profound factors in this disease. Certain races are comparatively immune to tuberculosis, when occurring it runs in them a milder and milder course; in other races it is more common, runs a more severe and shorter course. The Jews have a relative immunity to tuberculosis which they may have acquired from having lived many centuries in overcrowded and unhygienic quarters. The predisposition of the Irish and the Italians to tuberculosis manifests itself only after removal from their native environment. In the later generations after this removal this predisposition is gone, probably as a survival of the fittest. The proneness of the Italian immigrants to tuberculosis can be ascribed to the difference in occupation and the somewhat changed mode of life. The number of returning tuberculous Italians has been so large that their government has had to provide extra facilities for them. These immigrants died and succumbed in the attempts to be

transplanted on new soil and under new conditions. After all, then, the question of race and heredity is only one of physical powers of resistance; it is the dominant characteristic possessed by one race, which may be lacking in another, that determines immunity or predisposition.

The physical condition together with the habits of life prior to infection modify the course of this disease, since they bear on the ability of the patient to withstand the devitalizing influences of the disease. It is peculiar that such individuals as have had outdoor occupations, who have engaged in heavy work, and who have robust bodies, such as are found among sailors, workers in the construction trades and the like, often fare much worse, or are incapacitated over longer periods, than the average city product of poor physique when he is infected—although, to be sure, the census of the latter is much greater. An explanation may be found for this condition in the fact that those of poor physique and of indoor life and occupation react very quickly and favorably to the stimulation of the new environment and the beneficent effect of the new mode of living enjoined on the afflicted. In tuberculosis the ability to make a change is of prime importance in effecting a cure. In the robust who have previously lived or worked out of doors, there can be little change for the better in the matter of environment at least, although there can be much change by way of temperate living.

While absolute reliance cannot be placed on the physical signs to denote the extent of the lesion and therefore the prognosis and duration, yet the size of the lesions, when they are considered in conjunction with the physical condition of the patient, furnishes important data in arriving at the prognosis. A large area of lung involvement and the patient withal in good condition means either that the infection is mild and of slow progress and long duration, or what is less likely, that the patient is extremely resistant to a rapid and severe infection. A lesion large of size but of recent origin would have been so rapid in its course as quickly to sap the patient's vitality. On the other hand the slow progress has made possible the development of a large area without great physical detriment to the patient; the slow progress allowing the body to overcome each new inroad of the disease as it arises. At no time is the disease allowed to become severe enough to overwhelm the patient. Moreover, a small lesion, with the patient never-

theless in debilitated conditions, means a rapid virulent infection and low resisting power, since if this type of infection had been of long standing it is not likely that it would have been limited to this small area, and if limited for a long time, it would not have had so deleterious an effect on the patient. During this period the patient would have been immunized against the toxic effects of the disease and shown little ill effects therefrom.

A large lesion, therefore, with good physical condition has a good prognosis both for ultimate outlook and duration—under proper conditions. A small lesion with the patient apparently overwhelmed within the short time that the disease has been manifest has a bad outlook even under the best conditions. Of course, a small lesion with the patient in good physical condition—i.e. incipient tuberculosis—in the average individual offers an excellent chance of recovery within a comparatively short time. It is these incipient cases which were unrecognized before the present rather more delicate methods of diagnosis—and, indeed, many of them are still unrecognized. It was Virchow who proclaimed the now famous dictum that all persons at one time or another are infected with tuberculosis but that most of them recover without symptoms or diagnosis.

The previous behavior of the disease is an important factor in determining its subsequent course, duration and severity, as well as the ability of the patient, from the economic standpoint, to carry out the necessary regimen for cure.

Finally, the most important element in the prognosis of pulmonary tuberculosis is its early diagnosis. An early diagnosis means cure. A late diagnosis, one at any time after the incipient stage, requires a guarded prognosis. It is the function of the practitioner to make the early and accurate diagnosis in order that the treatment may be prompt and efficacious.

THE IMPORTANCE OF REST IN THE TREATMENT OF GRAVES' DISEASE.

In an exhaustive paper on the "Diagnosis of Thyroid Disease as Related to Surgical Treatment," presented at a recent meeting of the Medical Association of the Greater City of New

York, Dr. Martin B. Tinker of Ithaca, who is a recognized authority on the subject of goitre, made the remarkable statement that he had succeeded in reducing the risk of thyroid surgery to a fraction of one per cent. This, he said, had been rendered possible only by "team work" in the matter of diagnosis and particular attention to the after-treatment. A decision as to whether or not thyroid disease existed, and whether such disease, if present, were the chief cause of the patient's discomfort, frequently required most careful application and wise interpretation of (1) a general physical examination; (2) special examination, especially of the eyes and throat; (3) laboratory tests; (4) x-ray examination. He emphasized the necessity of post-operative care for from six months to a year; stating that prolonged rest was of the utmost service, and that without this the surgical operation could not effect much. In the treatment of exophthalmic goitre, rest is no less an essential element in cases in which surgical interference is not called for than in those in which this is necessary. Many authors, in writing on this disease, make no reference whatever to its therapeutic value, and it would appear that its importance is by no means generally appreciated.

In concluding a paper, published in the *Medical Record* for March 13, in which are recorded certain observations on clinical treatments for this disease (which she prefers to designate by the name introduced by Bainbridge—systemic goitre,) Dr. Mary Sutton Macy, neurologist to the Demilt Dispensary, New York, lays stress on the kind of rest necessary in re-establishing the normal physiological balance in a patient suffering from the affection. Rest, if both physical and mental, affords unhampered opportunity to the *vis medicatrix naturae* to restore such physiological balance and possibly produce a cure. In the required regimen she contends drugs, sera, hormones and other therapeutic means take their proper places, as crutches prescribed to sustain, for the time being, some crippled portion of the organism, and should therefore be given symptomatically, and not as remedies for the hyperthyroidism *per se*. Rest if properly enforced, requires considerable of the physician's time and personal attention since only very few patients know *how to rest*. The art of muscular relaxation and passive innervation of the muscles is a difficult one to ac-

ire, and a still more difficult one to teach to patient whose whole personality is an expression of active innervation and muscular tension; and this kind of rest must be minutely thought to one who is the subject of Graves' disease.

Incidentally, Dr. Macy suggests as a possible theory regarding the etiology of exophthalmic goitre that it is a pathological syndrome secondary to a profound disturbance of the physiological pubertal balance by exhaustion of the nervous system, either rapidly by strong emotions, such as fear and grief, or more slowly through long-sustained effort to gratify ambition (intellectual or physical). This hypothesis is based first, on the fact that certain parallels in the picture of pubertal physiological balance and hyperthyroid symptoms have been noted by various observers, and, second, the general admission by most authorities that shock is an etiological factor, and the history of pubertal shock in one hundred per cent. of the cases in a series of forty-four recorded in her paper. The occasional cases of hyperthyroidism observed in children under the extreme low variation of normal pubertal age (which has been reached at seven years) may possibly be due to some similar condition which must account for the equally occasional cases of precocious menstruation and other infantile abnormalities of sexual maturity. Again, the fact that so many cases of Graves' disease are not recognized—or, some claim, do not appear—until the third, fourth or even fifth decade of life, does not, it is intended, disprove the theory, since all authorities admit that hyperthyroidism is frequently masked for years, and often mistaken for neurasthenia, hysteria, chronic laryngitis, etc., prior to the appearance of the exophthalmos and the marked thyroid enlargement. If this physiological theory will bear dissection and proof, it will serve, the author believes, to explain in large measure why so many widely different types of treatment meet with similar successes and failures, dependent largely, if not entirely, on the extent to which the therapeutic measure, at least, is carried and enforced as an accompaniment.

SALARIES OF DISTRICT HEALTH OFFICERS.

IN the issue of the JOURNAL for March 11, we noted the appointment, by Dr. Allan J. McLaughlin, Massachusetts State Commissioner of Health, of the eight district officers who are to have charge of the administration of public health affairs under the direction of the state department of health. Under the law, the health commissioner was given the right to select and appoint these officers, but their salaries are to be established by the governor's council, and some uncertainty seems to have arisen in the determination of their compensation. At a recent meeting of the council to deal with this question, the following order was adopted, requesting the attorney-general's opinion on the interpretation of the statute dealing with this point.

"Ordered, that the attorney-general be and is hereby requested to give to the council his opinion concerning the legal effect of the first ten lines of Section 5, chapter 792, Acts of 1914, especially answering the following questions:

"1. In the event of the appointment of a district health officer by the commissioner of public health, with the approval of the public health council, taking place, is it necessary that the compensation, subject to the approval of the governor and council, shall be fixed before said district health officer is entitled to perform his duties?—or

"2. Is he so entitled to perform his duties after his appointment by the commissioner and approval by the council prior to the fixing of his compensation by the governor and council?

"3. Does the phrase 'shall not engage in other occupation and shall give their entire time to the performance of their duties,' prevent a district health officer from in any way practising his profession for his private gain?"

The attorney-general's decision on these questions has since been returned, and the Council on March 19 approved the salary schedule of the new district health officers.

ENFORCEMENT OF LAW FOR LOCAL TUBERCULOSIS INSTITUTIONS.

IN an editorial on the local care of advanced tuberculosis in the issue of the JOURNAL for February 25, we commented on the delinquency of various Massachusetts cities and towns in compliance with the law requiring the establishment of tuberculosis dispensaries in all commu-

nities of more than ten thousand inhabitants. During the past week, in accordance with a recent vote of the public health council, Dr. Allan J. McLaughlin, state commissioner of health, has issued a notification to thirty of these communities requiring them to comply with this statute before July 1 of the current year. The thirty cities and towns affected by this order are: Holyoke, Malden, Newton, Fitchburg, Taunton, Everett, Quincy, Chicopee, Medford, North Adams, Northampton, Beverly, Revere, Leominster, Attleboro, Westfield, Melrose, Woburn, Marlboro, Milford, Adams, Weymouth, Watertown, Southbridge, Plymouth, Webster, Methuen, Wakefield, Greenfield and Winthrop.

It is understood that the attorney-general will be asked to proceed against such communities as fail to comply with this request within the specified time. The law provides a fine of \$500 as penalty for failure in such compliance. It is further expected that a similar notice will be served upon larger cities which have failed to establish tuberculosis hospitals, as required by law, and that these communities will be given until September 1 to meet this requirement.

MEDICAL NOTES.

LOW NEW YORK DEATH-RATE.—From figures supplied by Dr. William H. Guilfooy, Registrar of the Department of Health, it is clear that the past week in New York City was most healthful. The great decrease in the mortality of the week ending March 6, 1915, continued during the past week, although not to as large a degree as last week.

Comparing the figures for the past week with the corresponding week of 1914, reveals a considerably decreased mortality for nearly all causes of death, with the exception of the degenerative diseases, organic heart and kidney diseases, in which the death-rate was approximately the same.

So far as the age periods of those dying last week are concerned, the figures show a great saving of life among the adults, including the extremely old.

The death rate was 1.1-3 points lower, which corresponded to a relative decrease of 151 deaths. The death-rate so far this year, namely 13.95, is considerably below that of the corresponding period in 1914, there being a decrease in the rate of 1.5 points.

NEGROES IN THE UNITED STATES.—The bulletin on negroes in the United States, issued on March 20, by William J. Harris, Director of the

Census, Department of Commerce, contains for the first time a statement regarding mortality among negroes. All previous census publications have given statistics for the total colored population, in which were included the Chinese, Japanese, Indians, and other non-whites. The data are shown for the registration area of the United States, the registration states and certain selected cities.

The negro population of the area was 19.7% of the total number of negroes in the United States in 1910, and the deaths numbered 49,499, with a death-rate of 25.5 per 1000 population—a decrease as compared with the rate in 1900, which was 29.4. The selected cities shown are the 57 registration cities which had, in 1910 a negro population of 2500, or more, for which comparable data are available in 1900.

In the 57 cities included in the table the death-rate among negroes in 1910 was 27.8, and that among whites 15.9 per 1000, the rate among the negroes being nearly twice as great as that for the whites. In the 33 northern cities the death-rate among negroes was 25.1 and that among white 15.7 per 1000, while in 24 southern cities the rate for negroes was 29.6 and that for whites 16.9. Thus the death-rates for each race were higher in the southern than in the northern cities, the difference between the races in respect to death-rate also being greater in the south.

Both negroes and whites show decreases in death-rate in 1910 as compared with 1900, when the 57 cities are considered in the aggregate, the decline for the negroes being 3.4 and for whites 2.5 per 1000 population. Every city in the south, except Key West, Fla., and Memphis, Tenn., showed a lower death-rate for negroes in 1910 than in 1900; the increase in Key West was only 0.2, while in Memphis it was 3.9 per 1000.

The general tendency appears to be in the direction of a declining death-rate for negroes in registration cities, the decrease being somewhat greater for negroes than for whites; as a result, the difference between the death-rate for negroes and for whites in these cities was not as great in 1910 as a decade earlier.

The question whether the decrease in mortality among negroes in 1910 as compared with that of 1900 was due to permanent causes, such as improved housing conditions, better medical attention, and in general improved sanitary conditions, and not to the absence of epidemics, is important and interesting. Undoubtedly one of the factors which has caused the decrease in the death-rate—which decrease is almost universal in the cities of the south—is the increase in home ownership among the negro population. The ownership of homes data for the northern states and cities are not available, and what is presented here relates only to the south. In the decade from 1900 to 1910 the number of homes owned by negroes in the southern states increased by

,912, or 31.4%; this increase covering increase in farm homes of 30,449, or 16.7%; and other homes of 72,463, or 49.8%.

LONDON DEATH-RATES IN JANUARY.—Statistics recently published show that the total death-rate of London for January, 1915, was 19.6 per thousand inhabitants living. Among the several districts and boroughs, the highest rate was in Southwark, a populous southern quarter, the lowest was 14.2 in Hampstead, an open district on the north.

COMMISSION FOR THE ERADICATION OF TYPHUS AND CHOLERA.—The American Red Cross Society and the Rockefeller Foundation recently made a joint offer to Dr. Allan J. McLaughlin, Massachusetts State Commissioner of Health, to go to Serbia as the administrative head of a commission for the eradication of typhus fever and Asiatic cholera. The funds necessary to finance this expedition were to be furnished partly by the Red Cross, partly by the Rockefeller Foundation, and partly by the Serbian government. Interesting and important though this expedition is, it is a matter of consultation and good fortune for the Commonwealth of Massachusetts that Dr. McLaughlin decided to decline this opportunity.

The position was next offered to Dr. Richard Strong, professor of tropical diseases in the Harvard Medical School and has been accepted by him. Dr. Strong sailed, on March 17, for Europe, as a member of the Harvard expedition—unit destined for service at the American Ambulance Hospital in Neuilly, Paris. It is surmised, however, that after landing at Marseilles he will proceed instead to Serbia. It is announced by the Red Cross that the necessary sum of \$50,000 has been procured for carrying out the work of this sanitary commission. The other personnel of the commission of which Dr. Strong is the head, will be as follows:—Chief sanitary inspector, Dr. Thomas W. Henshaw of Philadelphia; bacteriologist, Dr. Louis Zinsser, professor of bacteriology, Columbia University; clinical laboratory assistant, Dr. Andrew W. Sellards of the Harvard Medical School; clinical assistant, Dr. George C. Shattuck of the Harvard Medical School; assistant sanitary inspector, Dr. Francis B. Grinnell of the Harvard Medical School. Dr. Nicolle, the French expert on typhus, has been invited to cooperate with the commission. Charles S. Elby of Washington, lately connected with the United States immigration service, is disbursing officer and secretary.

PROMOTION OF DR. GORGAS.—It is announced from Washington, D.C., that Surgeon-General William C. Gorgas, U.S.A., has been promoted to be a major-general in the medical department.

AWARD OF THE BERLINER FELLOWSHIP.—It is announced that the Sarah Berliner fellowship

for women has been awarded to Dr. Janet T. Howell, a graduate of the Johns Hopkins University. This fellowship of \$1000 enables the recipient to engage in research in physics, chemistry or biology.

AMERICAN POSTURE LEAGUE.—The second annual meeting of the American Posture League was held in New York on March 13. Dr. Joel E. Goldthwait of Boston, vice-president of the league, delivered the leading address, on "Recognition of the Different Anatomic Types in the Understanding of Special Postures." Other addresses were delivered by Drs. William A. Howe, S. Josephine Baker, Anna L. Brown, Eliza M. Mosher, Henry L. Taylor and Percy W. Roberts of New York, and by Dr. F. R. Green of Chicago. The central committee on public health organizations, which met in New York on the same date and several of whose members are officers of the Posture League, also attended the meeting and the luncheon which preceded it. A meeting of the directors was held earlier in the day for the election of officers.

NATIONAL RADIUM INSTITUTE.—Report from Washington, D. C., on March 12, states that a second instalment of radium bromide, valued at \$19,000, prepared by the federal bureau of mines at Denver, Colo., has been turned over to the national radium institute for use in the treatment of cancer and other affections.

FREE VACCINATION FOR GOVERNMENT EMPLOYEES.—Report from Washington, D.C., on Mar. 13, states that the treasury department has directed the medical officers of the United States Public Health Service to provide free vaccination against smallpox or typhoid fever, or both, for all civil employees of the government engaged in interstate travel or in handling mail or other material for interstate traffic, whenever request for such vaccination is voluntarily made by the employees.

GRADUATE SCHOOL OF MEDICINE OF CHICAGO.—A report from Chicago on March 13 announces the proposed establishment in that city of a new and comprehensive school of medicine and sanitary science, to be known as the Graduate School of Medicine of Chicago. The foundation is expected to begin its work on May 1, and will have provision for 3000 students.

"The graduate school will not be conducted for pecuniary gain. Its sole object will be the advancement of medical science. Cook County physicians will receive post-graduate work free. Outside physicians will contribute a nominal sum. A central bureau will disseminate information regarding discoveries made and work accomplished. Eventually the foundation will be under the control of the large universities of Illinois, thus eliminating any politics or commercialism. No favors will be shown any faction of the medical profession. Already 250

'teaching' physicians and surgeons in all branches of the medical profession have tendered their services as instructors. More than 100 more are to be selected, each regarded as an authority. The foundation will be composed of a number of hospitals, sanatoria, and laboratories in Cook County. It is proposed to have departments of both curative and preventive medicine.

PHILADELPHIA DEATH-RATES IN 1914.—A recently published monthly bulletin of the Philadelphia Board of Health summarizes the monthly statistics of that city for the year 1914. The total death-rate for this period was 16.5 per thousand, an increase of 0.5 over 1913. Several diseases showed an increased incidence also over the preceding year. Of the preventable diseases, pertussis increased 39%, influenza 48%, tuberculosis 4%, infantile diarrhea 18%, and pneumonia 14%. Of diseases not amenable to control, heart disease showed an increase of 7% over 1913, nephritis 2%, and apoplexy 9%. On the other hand, typhoid fever showed a diminution of 51%, scarlet fever 20%, diphtheria 7% and measles 63%.

EUROPEAN WAR NOTES.—Report from New York on March 13 states that a gift of \$15,000 has been received in Philadelphia, enabling the medical school of the University of Pennsylvania to endow, for three months, a ward of forty beds at the American Ambulance Hospital at Paris.

Report from London on March 16 states that since the beginning of the war the loss of British horses has been at the rate of only 15% per annum, as compared with the loss of between 55% and 60% per annum in the South African war. This loss is more largely due to pleuropneumonia.

On March 19 the total of the New York Belgian relief fund amounted to \$981,831.64; the New York Jewish relief fund to \$573,267.00; the New York Red Cross fund to \$470,871.44; the American Ambulance Hospital fund to \$367,015.00; and the Prince of Wales fund to \$112,503.59.

On March 20 the total of the New England Belgian relief fund amounted to \$236,431.76; the Massachusetts Red Cross fund to \$112,691.30; the Boston Jewish relief fund to \$48,907.70; and the Boston German relief fund to \$26,035.84.

BOSTON AND NEW ENGLAND.

MEASLES AND PERTUSSIS IN WAKEFIELD.—Report from Wakefield, Mass., on March 14 states that measles and whooping cough are, at present, epidemic in that town. Over 125 cases of measles have recently been reported, and it is expected that it will be necessary to close several of the local schools.

BOSTON DISPENSARY.—A recent report of the Boston Dispensary states that the number of patients who visited that institution during the month of February, 1915, was 8251, a marked increase over the preceding month and the corresponding month of last year.

PREVENTION OF CANCER.—On Wednesday afternoon, March 10, Dr. Edward Reynolds of Boston, vice-president of the American Society for the Control of Cancer, delivered an address on the prevention of cancer before a meeting under the auspices of the committee of the American Medical Association on public health education and the department of public health of the Women's Municipal League of Boston. The total mortality from cancer in the United States in 1913 was about 75,000. A considerable number of such deaths may be regarded as preventable. On Wednesday afternoon, March 17, Dr. Joseph L. Goodale, of Boston, spoke under the same auspices on "Some Disturbances of the Nose and Throat Which Impair Efficiency."

REPORT OF THE BUTLER HOSPITAL.—The recently published seventy-first annual report of the Butler Hospital of Providence, R. I., records the work and progress of that institution for the calendar year 1914. During this period 258 patients were treated in the hospital with only 20 deaths. Several important special methods of treatment were particularly tested, especially the use of salvarsanized serum in general paresis and tabes. Twenty nurses were graduated from the training school. The superintendent's report emphasizes the urgent need of an adequately equipped gymnasium, and the trustee call attention to the work already done in the way of fire protection and the need of important new outbuildings.

STATE CONFERENCE ON TUBERCULOSIS.—"What the Anti-Tuberculosis Organizations Can Do to Help the State Department of Health," is the subject to be discussed by the Commissioner of Health, Dr. Allan J. McLaughlin, at the first annual meeting and all-day conference of the Massachusetts Anti-Tuberculosis League, to be held at the Twentieth Century Club, 3 Joy Street, Boston, Thursday, April 1, 1915. The Secretary of the Trustees of the Massachusetts Hospitals for Consumptives, Dr. John B. Hawes, 2nd, will speak on "The Situation in regard to the New Tuberculosis Hospitals," and Dr. Walter G. Phippen of Salem will give some interesting facts in regard to the local tuberculosis dispensaries, required by law. At the afternoon session, to be held at 2.30, Dr. Walter P. Bowditch of Clinton will speak on "The Reporting of Tuberculosis by Physicians," and Michael M. Davis, Jr., director of the Boston Dispensary will discuss "Tuberculosis Associations and Health Educators." "The Responsibility and Opportunity of the Teacher in Preventing Tuberculosis" will be the subject of the evening session.

culosis" is to be treated by Dr. Thomas F. Harrington, director of school hygiene, Boston, followed by an address on "Inspection of School Children," by Dr. Francis L. Dunham of Brookline. The chief inspector of incorporated charities of the State Board of Charity, Miss Amy F. Fenton will tell of "Some Observations of the Anti-Tuberculosis Work in This State," after which a general summing up of the afternoon session will be made by Mrs. William H.throp of Newtonville. The conference is open to the public and will be in charge of its president, Dr. Vincent Y. Bowditch.

HARVARD UNIVERSITY REPORTS.—The recently published reports of the president and the treasurer of Harvard College include in the same volume, the reports of all the departments of the university for the academic year 1913-14. The president, in his report, calls attention to the opening of the Children's, Infants', Peter Bent Brigham and Collis P. Huntington Hospitals and to the appointment, by the United Fruit Company, of Dr. Strong as director of its hospitals in the West Indies and Central America. He also discusses various problems of internal organization of the Harvard Medical School, especially the questions of examinations and finance. Dr. Bradford's report, as dean of the Medical School, describes its activities during the year and refers in detail to the work of the several departments. He presents an interesting table, showing the comparative standing of the members of each class in the school at oral examinations during the five years from 1910 to 1914, inclusive. Dr. Horace D. Arnold, in his report as dean of the Graduate School of Medicine, calls attention to the slight falling off in the number of students and receipts from the previous year, due apparently, to the general financial situation and to the European War. The report of the dental school, by Dr. Eugene J. Smith, summarizes the instruction and the clinical work in dentistry done at the school. During the year a total of 23,936 operations were performed by students and instructors in the school.

REPORT OF BOSTON MEDICAL LIBRARY.—The recently published thirty-ninth annual report of the Boston Medical Library records the activities of that institution for the year 1914. During this period there has been a net gain in membership of 42, and an increase of 4195 volumes and 984 pamphlets in the library.

CASES OF INFECTIOUS DISEASES reported to the Boston Board of Health for the week ending March 16, 1915: Diphtheria, 78, of which 2 were non-residents; scarlatina, 72, of which 10 were non-residents; typhoid fever 1, which was non-resident; measles, 167; tuberculosis, 56. The death-rate of the reported deaths for the week was 17.63.

Obituary

RIGHT HON. SIR GEORGE TURNER.
F.C.M.G., M.D. LL.D.

THE RIGHT HONORABLE DR. SIR GEORGE TURNER, F.C.M.G., has recently died at Colyton, Devonshire, England, of leprosy contracted during his research work on that disease in South Africa. He was born at Melbourne, Victoria, on August 8, 1851, and received his medical education in that country, where he became prominent also in public life as a member of parliament, minister of customs, minister of health, minister of defence, and solicitor general. In 1894 he became premier and served also as president of the federal council of Australasia, chairman of its standing committee, and member of the Australian national federal convention. In 1901 he became treasurer of the Australian federal government.

Dr. Turner's most important medical work was done in South Africa, where he discovered the serum by means of which the rinderpest was eradicated. He served in a medical capacity during the Boer War and arrested an epidemic of typhoid fever, which was sweeping the military hospitals and concentration camps at that time. In 1901, while supervising the suppression of the second great epizootic of rinderpest, he became interested in the study of leprosy in the leper asylum in Pretoria, where there were nearly one hundred Dutch and native patients. It was during this work, which Dr. Turner pursued for several years, that he himself contracted leprosy, after which he withdrew from his public offices and devoted himself solely to the study of that disease. A few years ago he finally returned to England, where he settled in a country estate in Devonshire, to await the end.

For his public services Dr. Turner was created a baronet in 1897. He is survived by his widow.

Miscellany.

MEDICAL EDUCATION IN CHINA.

IN the issue of the JOURNAL for March 11 we commented editorially on the work and recent progress of the Yale-in-China Medical School. On March 4 a letter from Dr. Edward H. Hume, chief of the medical department of Yale-in-China, outlined, in a New Haven publication, plans for the new Yale Hospital at Hunan, China.

A campus is being planned for which twenty acres of land have been purchased outside the city wall of Changsha, and \$56,000 has been raised by Yale men to construct buildings

on the plot. The Yale Hospital will be built on this campus, and a well-known firm of New York architects has already drawn plans for the buildings, which include, beside the hospital building, a dormitory, chapel and four buildings for professors.

"For eight years the Yale College in China has been carrying on its work within the city walls in crowded, unsanitary quarters. There are now enrolled 140 pupils in the school and college. Recently interest in this oriental branch of Yale College has become so manifest that many alumni gifts have been forthcoming. The hospital is the gift of a well-known Yale man."

Interest in occidental medical education in China is not limited either to Yale or to Harvard, though these have been the first American universities to establish and maintain hospitals and schools of medicine in that country. On March 7 it was announced in New York that the Rockefeller Foundation has decided to undertake a comprehensive plan for the improvement of medical and hospital conditions in China.

"For this purpose the Foundation has established a special organization to be known as 'The China Medical Board of the Rockefeller Foundation,' and plans as the first step toward effective work the development in China of medical education. This will include aid for the two or more medical schools in China, described as inadequately equipped, the strengthening of the staffs of the mission and other hospitals, assistance in the establishment of two modern tuberculosis hospitals, and the establishment of six \$1000 scholarships, with travelling expenses, to enable Chinese graduates in medicine to prosecute further studies abroad, and of five scholarships to enable Chinese nurses to obtain training in this country."

In the establishment of these fellowships the purpose of the Foundation is to organize a body of Chinese physicians who in time will be able to assume leadership in teaching the medical sciences in their own country.

The action of the Foundation was based on the report of its special commission which, last year, made a personal study of the conditions of public health and medical practice in China.

"The commission was composed of Harry Pratt Judson, president of the University of Chicago; Dr. Francis W. Peabody of the Medical School of Harvard University; and Roger S. Greene, then consul general of the United States at Hankow.

"The China Medical Commission made numerous recommendations designed to meet the situation systematically, one of the primary ideas underlying the whole plan being to enlist the actual coöperation of both the missionary agencies and the Chinese people.

"The report of the commission has in its gen-

eral outline been adopted by the Foundation as a basis for its work in China. Details, however, will be studied separately and each project will be taken up for definite decision."

In the report of this commission it is pointed out that,

"Not only have many preventable and easily curable diseases prevailed there, almost unchecked, from the earliest days down to present times, but intercourse with foreign countries and modern methods of communication have introduced into regions previously unaffected such scourges as bubonic plague and have contributed largely to the spread of other dangerous infections. So also have modern systems of transportation and of industry brought in an entirely new series of accidents and occupational diseases with which Chinese civilization is not yet prepared to cope. A special obligation, therefore, rests upon Western civilization to mitigate this suffering, for part of which it may be held directly responsible."

The personnel of the China medical board is further announced as follows:—

"John D. Rockefeller, Jr., chairman; Wallace Buttrick, director; President Harry Pratt Judson, President Frank J. Goodnow, Dr. Simon Flexner, Wickliffe Rose, Jerome D. Greene, Starr J. Murphy, John R. Mott, Dr. Francis W. Peabody, Dr. William H. Welch, Frederick T. Gates, E. C. Sage is secretary of the board, and Roger S. Greene is to be the resident director in China.

"The director of the board will have general administrative supervision over all its activities and particularly over the home office in New York. The resident director in China will have his headquarters in Peking.

"The plan outlined by the commission looks forward to the development of medical education in China as the first step toward effective work. Before hospitals can be established in large numbers, and before extensive work in public health and preventive medicine can be done, a large body of well trained doctors qualified to man hospitals and to administer public health measures must be secured.

"With a view to giving Chinese graduates in medicine opportunity to obtain their hospital training under proper supervision and to practice under favorable conditions, the Foundation intends to strengthen the staffs of the mission hospitals and other hospitals already existing in the vicinity of the medical schools aided.

"In hospitals thus more fully manned, young Chinese doctors will be employed as house officers or as visiting physicians, their compensation, when judged necessary, being paid by the Foundation. It is hoped that an intimate relation may be established between these hospitals and the medical schools near which they are located.

"It is proposed to enable the missionary societies to send out a larger number of well-trained nurses. An appropriation has also been made

or five nursing scholarships to enable Chinese nurses to come to the United States and secure first-class training at some of the leading schools in this country. A small appropriation has been made for the translation of nursing text-books, and aid may be given to some nurses' training schools.

"China suffers very greatly from tuberculosis, and has at present no institution specially equipped for the treatment of this disease. The Commission, therefore, recommends that the foundation assist in the establishment of two model tuberculosis hospitals built and equipped according to the best modern practice."

Correspondence.

PARIS LETTER.

THE WOUNDED ON THE FRENCH BATTLE LINE.

(From Our Special Correspondent.)

PARIS, February 17, 1915.

Mr. Editor: In my last letter I endeavored to convey some idea of the state of humiliation into which this horrible war has plunged the surgical fraternity; may next be of interest to inquire a little into the question of the causes of this lamentable overthrow. But first let us look at a few real scenes representing what actually takes place on a battlefield of today. About a year ago a maid I had had for some time married a non-commissioned officer of artillery. This man appeared to me to be quite a decent chap, but very much like the ordinary run of men of that class, good-looking, with a big moustache and becoming uniform. He left at once for the Luxemburg front at the outbreak of war with his battery of seventy-fives, and ever since that time has been sending his wife letters that show me how deeply mistaken I was in my estimate of this young fellow, who is something quite out of the ordinary. He began up at once in all the early frontier fighting, retreated with his guns from position to position, had his horse shot down to pieces beneath him, was promoted, and ended up at the battle of the Marne where for five days and nights his cannon hurled death and destruction into the ranks of the Germans. Since that time his battery has seen less active service. He writes to me on quires, in a small neat hand, and in a style that is quite extraordinary for a man in that station; his long and minute descriptions of the fighting are so real that you can almost fancy yourself present; and they are interspersed at intervals with lurid and sulphurous curses and execrations of the enemy that ought to have set the mail-pouch on fire, alternating with transports of love, poetry and sentiment for the young wife he had to leave so soon behind him, and patriotic and religious effusions. The whole thing makes a mixture such as I imagine was never seen in print before, and I have strongly advised the young woman to keep these letters for possible literary use. In the meantime here are a few extracts concerning the effects of artillery fire, as an illustration of the fact which must always be borne in mind in speaking of the surgery of this war, that it is a *war of artillery*, whereas rifle fire has been relegated altogether to a lower plane.

After describing the death of his adjutant, who with his horse was simply blown to bits, so much so that they could hardly find enough of him to warrant

burial, he continues: "I was sent ahead to reconnoitre, and after fastening my horse to a tree, crawled as flat as I could on all fours for several hundred yards, fearfully bothered and scratched by the briars that seemed to be everywhere. Finally I reached a hummock from which I could make out through the glass masses of German infantry and artillery crouching and hiding in some outfields near a wood. Signalling this back to the captain of the guns, which had been masked separately here and there, they at once opened fire. *Never* shall I forget those outfields! We felt for the exact range with shrapnel, and as soon as we had got it we let them have it with high explosion shell! Ah! the horrors of war. . . arms, feet, fragments of bodies danced and flew in the air; we rallied and we mowed; other cannon and batteries joined in, and we hid them all under trees, or covered them with fresh branches, so that the enemy's aeroplane could not spot us. The Germans, on their side, 'watered' our region with heavy guns, but without finding us; a wood interfered with their work, so that their shells passed over and back of us. In three hours' time we killed upwards of 2000 of the troops discovered in those fields; three-quarters of them must have remained there for good, only a small portion having the courage to rise and make a bolt for it, so terrible was the effect of our shell-fire."

Later on; the same day.

"The Captain sends me for orders to the major, and then to the general, and we are informed that two kilometres to our left four mitrailleuses are onto our infantry and doing much damage. We leave our position at full trot, and take up another one, and then once more we give it to them with melinite shells. . . melinite shells, . . let her go, boys! I am lying on a ridge 300 metres in front of our cannon, in observation with the captain, who is now beyond shouting, his voice having given out; so he tells me the elevations and corrections and I yell them back to the guns. We are next notified that some German infantry is massed in a ravine in a certain direction, so we lengthen our range, and *roôff!* . . *roôff!* . . on it goes! The enemy is finally driven out, and our men of the line find 800 dead in that place, with three mitrailleuses out of service."

And so he continues, by the chapter. When he has written himself dry one day he closes and takes the story up in his next. At the Marne a big German shell falls right among his "avant-trains" (horses and caissons), hurling him head over heels in a cloud of asphyxiating smoke; but he picks himself up without a scratch, to find four of his gunners laid out, three severely wounded. Another shot kills nine horses and sets the shells in his caisson aburning; "but," he explains to his wife, "as they were not 'set' they merely burned with a yellow fume, and did not explode!" According to the German casualty lists, in some of those early encounters, when they simply hurled on battalion after battalion in massed formation against such fire as this, certain regiments lost 2500, 2800, 3000 and over, out of their approximate 4000. At one of the battles on the Meuse a French artillery officer wrote that *for seven consecutive hours* his guns fired into visible masses of Germans, until men and officers were utterly exhausted and practically deaf! Such tales as these enable us to understand that in this conflict the casualty lists have been something altogether unprecedented: after the battle of the Marne the French are said to have had upwards of 110,000 wounded to cope with, and the entire losses of the Germans are now certainly well up in their second million,—in fact they were authoritatively reported recently in the House of Commons as 2,250,000. These accounts also enable us to understand what the nature of a large part of these wounds must be. The modern rifle-wound, that does not kill outright, is a fairly safe investment; the force of penetration of the shrapnel ball is slight, and can be stopped by a helmet, tin-can, or even leather strap,—so that if you do not happen to be directly in the axis of progression

of the projectile itself previous to explosion, your chances here are still fair; but the melinite, high-explosive obus of the French artillery is a *terrible* affair, and when the war is over the Germans will have something interesting to report on this score!

There has been a pretty widespread feeling among people here as regards the handling of the French wounded; all has not been altogether as it should be, in this war. All reports agree that the soldiers have been *admirably* fed, and that they have been well looked after, in general, as regards outfit, munitions, and even comforts; so that everything has gone as well as it could in wartime, until a man had the misfortune to be wounded,—from then on accounts have been less satisfactory. To such a point has this feeling been carried that a *député*, himself under arms, told me personally that he had tackled the head of the Service de Santé one day, and wagging his finger offensively under his nose, had said to him: "Monsieur! the day when some French mother *kills* you, she will have rendered service to her country." I don't believe myself that this fellow ever did anything of the sort, because if he had the other chap would have knocked his head off then and there; I merely cite the incident to show how he felt on the matter. On the other hand, the army medical department claims that they were utterly swamped; that no one ever expected to have to handle such quantities of wounded. I read in the papers that at one period, on the western scene of war only, the wounded were pouring back to Germany at the rate of forty to fifty thousand *per week*. However, all this may be, let us take a given man, wounded on the battlefield, and see what is likely to become of him, in *our* neighborhood: this may lead us to some explanation of this universal suppuration, with gangrene and tetanus.

Not only has a large percentage of wounds in this war been due to bursting shells, but the situation of the wounded has been made infinitely more serious by the increased range of modern arms, and by the aeroplane. The depth of the danger zone back of the actual firing-line is now several kilometres, and, save when your own side happens to be advancing pretty steadily, any such thing as first-aid or stretcher work *during the daytime* is practically out of the question,—it cannot be undertaken until night, and even then often at the greatest risk, with all these aerial flares, and searchlights, as the melancholy tale of killed and wounded among the army-surgeons reveals only too plainly. Consequently, the wounded man must either bandage himself with his emergency-dressing, or call on a comrade to do so. I do not know whether this dressing has been modified or not; but certainly in the early part of the war it was quite insufficient for anything except the simplest of wounds, bullet wounds of the hand, fore-arm, foot, etc. For wounds of the thigh, shoulder, thorax and even head, it proved quite inadequate; everyone knows how much material is necessary for a thigh or thorax wound.

Again. Although everyone has been using tincture of iodine over here for years now as an emergency antiseptic, the war had been in progress a good three months before it occurred to anyone that it might be a good thing to add a little tube of this material to the soldier's emergency package; and even when this was done the tube was really too small for serious shell wounds. A man with part of his thigh or hip blown away was not likely to derive much protection from a tiny tube containing one c.c. of tincture of iodine, yet these were really the men who needed it, as the bullet and shrapnel wounds, as a general thing, were fairly clean and took care of themselves.

According to schedule the wounded man was supposed to make his way in some manner or other to the *poste de premier secours*, whence he was to be forwarded to the supporting ambulance, and from there to the nearest evacuation railroad station. This looked very nice on paper; but with a battle-front of

some hundreds of kilometres, and with the wounded piling up at the rate they did during active operations, one does not need to have a very active imagination to realize what actually occurred. Badly wounded men, with farcical dressings or none whatever, lay for days before they were found at all. Such as reached the ambulance accumulated there, the staff was overwhelmed, and supplies gave out. It was found that the devices for clearing out the ambulance wounded and getting them off to partial salvation, the railroad, were quite inadequate; such motor ambulances as existed were too big and too heavy, what was required being a small, handy, light affair, that could go over any kind of ground and turn round on a five-franc piece. Even when these wretched creatures reached the trains, their troubles were not even half over! A general's problem is first to have troops, and to supply them with all the munitions they require; secondly, to feed them properly; and only in the third place, and when *everything* else has been seen to, can he think of his waste, the wounded! The result can be imagined. The wounded had to be put in such care as was available, and had to be transported on the devil's own schedule,—that is, every other sort of train, of whatever description, had the right of way against them. When Joffre was in a hurry he sent his troop-trains along *both* tracks, that is, on both the up and down lines; consequently every train of wounded had to be on a siding until the entire strategic movement had taken place! Now as they were pretty usually freight cars, without the slightest pretence to a convenience, non-intercommunicating, and very often without surgeons, nurses, dressings or food,—you can once more let your imagination dwell on the situation and see the tableau. One of the members of the medical society here reported recently an instance in which a consignment of typhoid cases had been *five days* on their way to Paris from the front, an actual running distance in time of peace of between two hours as a minimum and five as a maximum; these patients appear to have had no care of any kind under way, not even enough to drink, and the mouths of several of them were in such a state on arrival that they developed suppurative parotitis from which they died.

Quantities of wounded were evacuated in trains that had transported cavalry and artillery. Furthermore, at all points where a damming up of patients occurred, there was no question of beds for them, of course, and they were put in every available quarters, usually on straw,—in box-cars, canal-boats, churches, freight-sheds, etc. Is it, then, any wonder that those hundreds of cases of tetanus occurred, with the disorder's well-known, frightful mortality? Nor had any provision been made for an adequate supply of anti-tetanic serum, nor was it in the proper place, in the very first line,—since its only action is as a preventive. It is rather a curious point to know that tetanus has developed in men without any wound whatever; I know of a case in which a man died from tetanus after a simple frostbite of the foot; and Sicard recently reported three other similar instances! This really seems like hard luck.

However, supposing our man past all the obstacles already referred to, was he then in a safe harbour? I am very much afraid not. The greater part of this work consisted in the most serious form of major surgery,—the very biggest thing of its kind. Now I need scarcely remark that under ordinary circumstances really first-class surgeons are few and far between, and that even the cream of these have never seen such butchery as they have been up against daily since the war began. These men, therefore, could not even *begin* to cover the ground, and by far the larger part of the wounded had consequently to be turned over to just pretty much anybody. Up to a certain point this was of course an ineluctable necessity; it was not possible to keep on hand a sufficient number of trained surgeons for the eventuality of such a war as this. But there is a side to the question that has

hitherto not been made clear to me. That in the early stages of the war, when Paris was actually menaced, the authorities should have been opposed to letting the wounded be brought to the capital, where were all the facilities and highest skill, is more than comprehensible; but that this should have continued to be the case all through the war, is quite beyond my mental grasp. Numbers of well-equipped and well-staffed ambulances in this city have been given up, because they never saw a soldier. The administration's main idea seems to be, *anywhere* rather than Paris! It is fair to presume that there must be grounds for this attitude; but they are certainly not apparent to the man in the street.

We now come to the final point in this matter,—the nursing of the wounded. Here we are on terribly dangerous soil; walking on egg-shells is mere child's play by the side of this burning question. It has, of course, long been known that these people have not kept pace with other countries in matters of nursing the sick. Be the reasons what they may, the fact is incontrovertible, and admitted by them without circumlocution. Physicians who have spent any time in the wards of a Paris hospital have seen for themselves how matters stand there in time of peace; and anyone who has practised here knows about what goes on in cases of illness in private houses. With a view to meeting the demand that everyone foresaw must arise in the event of war, a variety of women's organizations were formed, some social, others religious and still others among ladies merely desirous of being of use and of doing their duty in the hour of need. Everyone recognized the devotion, willingness, energy and heart that these ladies have put into their almost superhuman task; but I think that just as everyone sees that the ordinary local practitioner, the man who under normal circumstances would pass a bad night in anticipation of the removal of a woman from his most valued patient, is absolutely incapable of rising to the emergency of the major surgery of warfare, so everyone now sees that no amount of kindness of heart or untiring zeal can take the place of the trained professional nurse at the bedside of a dangerously-wounded man. War-nursing does not consist in "the soothin' of fevered brows," as has been picturesquely remarked, and it is really necessary that a suitable nurse should know such details as which end of a bedpan to present to a bedridden patient. I refer here to an incident that actually occurred! In fact, if I may be allowed so to remark, I could here a tale unfold, but must refrain, the atmosphere being altogether too charged with electricity. It would not surprise me much if one of the happy outcomes of this dreadful war will be the introduction into France of the professional nurse as understood in England and America.

In conclusion,—I think that I have said enough, many, many times enough, to explain why the wounds in Paris suppurate, and why the surgical clan's pride is reposing humbly in the dust. "S."

PATENT MEDICINES AND QUACKERY.

BOSTON, MARCH 12, 1915.

Mr. Editor: Within a few weeks Mr. Norman Hapgood spoke before a representative body of physicians, complimenting them on their virtues as members of a noble profession, and frankly telling them of some of their faults. Mr. Hapgood is a staunch friend of the medical profession and should be no stranger to it. He is a standard bearer in our fight against Patent Medicines and Quackery. The *Journal of the American Medical Association* is doing notable work, but is hampered in its influence by being a medical publication. The medical profession certainly should not need education in the matter of the harmfulness of the nostrum. The exploitation of one "fake cure" after another, however, classifies the individual phy-

sician's previously vague information. Of vastly greater significance is the work done in the popular press which, as it were, hits the bull's eyes and is disseminated among the innocent victims of this great evil, who need education in the dangers of the patent medicine habit. The *Harper's Weekly* is prosecuting a vigorous fight against this monster. The medical profession by an intelligent and hearty cooperation could at least hold the mirror up so that the fighter might sever the Gorgon's head. As physicians we can aid by making individual conversions and by never again prescribing a patent article just because of its convenience. Of course it does not always do harm, but every additional bottle sold encourages somebody to make his own diagnosis and get to the stage where medical science cannot succor him.

The least we can do at once is to help Mr. Hapgood by subscribing to the *Harper's Weekly* and spreading the gospel to those in our waiting rooms.

Very truly yours,

HUGH P. GREELEY, M.D.

SOCIETY NOTICES.

NORFOLK SOUTH DISTRICT MEDICAL SOCIETY.—Meeting for medical improvement at United States Hotel, Boston, Thursday, April 1st, 1915, at 11:30 A. M.

Reader, John W. Lane, M.D., of Boston, Mass., for M. T. Sweeney, M.D., of Norfolk Downs. Subject: Appendicitis.

F. H. MERRIAM, Sec.,
South Braintree, Mass.

NEW ENGLAND OTOLOGICAL AND LARYNGOLOGICAL SOCIETY.—The next meeting of the New England Otological and Laryngological Society will be held on Tuesday evening, March 30th, at the Boston Medical Library at 8 o'clock. Program:

1. Gunshot Wound of Orbit and Pharynx, Dr. W. F. O'Reilly.
2. Fatal Hemorrhage Following Tonsil and Adenoid Operation, Dr. E. A. Crockett.
3. Death Immediately Following Tonsillectomy Under Local Anesthesia, Dr. D. Crosby Greene.
4. An Operation for Chronic Frontal Sinus Suppuration, Dr. Howard A. Lothrop (By invitation).
5. The Type of Voice in Tabes, Dr. W. B. Swift (By invitation).

WILLIAM F. KNOWLES, Sec.

NEW ENGLAND BRANCH OF THE AMERICAN UROLOGICAL ASSOCIATION.—There will be a meeting of the Society on Tuesday, March 30th, at 8.15 P. M., at the Harvard Club of Boston. Program:

1. Presentation of specimens, instruments, etc., and the report of cases.
2. Experimental and Clinical Observations on the Blood Pressure in Spinal Anesthesia, Dr. George G. Smith, Boston.
3. A New Preparation for Pyelography, illustrated, Dr. E. L. Young, Jr., Boston.
4. Some Unsettled Points in the Preparation for and Technic of Suprapubic Prostatectomy, Dr. Paul W. Pilcher, Brooklyn, N. Y. Discussion.

R. F. O'NEIL, M.D., Sec.

THE NORFOLK DISTRICT MEDICAL SOCIETY.—A regular meeting of the Society will be held at the Boston Consumptives' Hospital, 249 River street, Mattapan, Tuesday, March 30th, at 3:30 P. M., sharp.

Tour of the Hospital, 3:30 to 5:00 P. M., business meeting and program, 5:00 P. M. Program:

1. The Organization and Management of the Consumptives' Hospital, Edwin A. Locke, M.D.
2. Relation of the Private Physician to the Out Patient Work of the Boston Consumptives' Hospital, Cleveland Floyd, M. D.
3. Tuberculosis in Children and Adults with New Aspects on the Von Pirquet Test, T. J. Murphy, M.D.

Dinner at 6:30 P. M.

The censors will meet May 13th, at 2:00 P. M., for the examination of candidates.

BRADFORD KENT, M.D., Sec.
798 Blue Hill Ave., Dorchester

CHANGES IN THE MEDICAL CORPS, U. S. NAVY, FROM FEB. 12, TO MARCH 13, 1915.

February 15. P. A. Surgeon H. W. Cole, detached, *San Diego to Colorado*.

February 15, Surgeon L. L. Von Wedekind, to Marine Recruiting Station, New York, N. Y.

Asst. Surgeon A. T. Weston, M.R.C., detached, Marine Recruiting Station, New York, N. Y.

February 23. Asst. Surgeon W. E. Stevens, commissioned, Jan. 23, 1915.

February 26, P. A. Surgeon H. F. Lawrence, detached, Hospital, Newport, to New York Hospital.

March 1, Surgeon C. E. Ryder, detached, *Cincinnati* to home, wait orders via March 15, Transport.

P. A. Surgeon Heber Butts, detached, *Monterey*; to home, wait orders, via April Transport.

Asst. Surgeon P. B. Ledbetter, detached, Naval Hospital, Olongapo, P. I., to home, wait orders, via March 15 Transport.

Asst. Surgeon R. H. Laning, detached, *Saratoga* to home, wait orders, via April 15 Transport.

Asst. Surgeon R. F. Jones, detached, Naval Hospital, Canacao, P. I. to home, wait orders.

March 3, P. A. Surgeon J. C. Parham, commissioned from July 7, 1914.

March 10, Surgeon H. C. Curl, detached, *West Virginia* to *Maryland*.

Surgeon J. D. Manchester, detached, *Maryland* to home, wait orders.

P. A. Surgeon J. C. Parham, detached, *St. Louis*, April 1, 1915, to home and wait orders.

INTERSTATE ASSOCIATION OF ANESTHETISTS.

The Interstate Association of Anesthetists will hold its organization meeting in conjunction with the Ohio

State Medical Association in Cincinnati, Ohio, May 4-5, 1915, at which time an elaborate scientific program devoted exclusively to recent advances in anesthesia and analgesia will be presented.

Headquarters, assembly room and exhibits will be in the New Hotel Gibson, in which all the sections of the Ohio State Medical Association will also meet. An informal organization dinner will be served on the evening of May 4, after which the visiting anesthetists will be the guests at a smoker, of the local entertainment committee, headed by Dr. E. O. Smith. Visiting ladies will be entertained by Dr. Nora Crotty and her committee at a reception and theatre-party.

Anesthetists, surgical and dental, as well as interested surgeons and general practitioners who wish to participate in the proceedings are cordially invited to attend. For further information and dinner reservations address,

F. H. McMECHAN, M.D., Secretary,
1044 Wesley Ave., Cincinnati, Ohio.

SOCIETY NOTICE.

NEW ENGLAND PEDIATRIC SOCIETY.—The thirty-seventh meeting of the New England Pediatric Society will be held in the Boston Medical Library, Friday, March 26, 1915, at 8.15 p.m.

The following papers will be read:

1. "The Management of Breast Feeding with Case Reports," Dr. C. K. Johnson, Burlington, Vt.
2. "Air and Water as Curative Agents," Dr. Roland G. Freeman, New York City.

Light refreshments will be served after the meeting.

E. M. BUCKINGHAM, M.D., Pres.
RICHARD M. SMITH, M.D., Sec.

APPOINTMENTS.

BOSTON DISPENSARY.—At the last meeting of the Board of Managers, the following appointments were made: Consultant pathologist, *Dr. Frank B. Mallory*; *Dr. Wolfert G. Webber*, assistant to physicians, General Medical Department; *Dr. Harold B. Eaton*, assistant to the physicians, General Medical Department; district physicians, *Dr. George H. Binney*; district physician, *Dr. William F. Temple, Jr.*

STATE HEALTH COUNCIL.—Governor Walsh has appointed *Mr. William P. Nickerson* of Norwood, Mass., to succeed *Dr. Milton J. Rosenau* as a member of the Massachusetts State Health Council.

RECENT DEATHS.

DR. HORACE THAXTER SEARS, who died of pneumonia in Boston recently, was born at Medfield, Mass., on May 10, 1867. After studying dentistry, he settled in Boston where he continued active in the practise of his profession until his death. He was unmarried.

DR. HENRY S. NOBLE, who died at Waterbury, Conn., on March 16, was born in 1844. He was a graduate of Tufts College and of the New York College of Physicians and Surgeons. Since 1900 he had been superintendent of the Connecticut State Hospital for the Insane.

CHARLES SEDGWICK MINOT, M.D.*

By W. T. PORTER, M.D., LL.D., BOSTON.

CIRCUMSTANCES, which should have prevented the career of Charles Sedgwick Minot, contributed largely to its success—the usual paradox. He was born not merely a Bostonian, but a legendary Bostonian. All the crushing disadvantages of an assured position, binding traditions, and a competence, were his. The times themselves were not propitious. The range of thought was narrow. Boston was no longer distinctively a caravan route. Strange cargoes were less frequent. The China seas widened fewer horizons. New people were coming in, floating on the tides of unearned increment. Hardy explorers from the fabled West discovered the North Shore. The old society, solicitous for a point of view justly regarded precious, took refuge in its trenches. The use of Christian names in conversation rose from a convenience to a shibboleth. The spirit of the times was aptly characterized by the President of Harvard University, when he called the Harvard Medical School of that period a dinner club. Those were provincial days in town and nation.

Much may be said of the charm and indeed the real value of limited societies, but they are unfavorable to the development of original minds. On the other hand, once the inertia of position is overcome, the virtues of these particular defects are admirably sustaining. No doubt the Bostonian of literature was a creature never seen on land or sea, yet the Boston spirit was

nevertheless a living force. There rests not the faintest doubt that a provincialism which pitched the note upon honesty of purpose, industry, and almost unexampled devotion to the public welfare, gave to the neophyte in science the indispensable weapons of his lifelong fight. In Minot's hands they were never tarnished; honesty, industry, and public spirit were undimmed to the end.

These attributes, though sufficient for salvation in the ordinary walks of life, are but the tools of thought. The priceless gift is the power to see how known phenomena may be so combined as to reveal new truth. In the last analysis, the setting of fruitful problems is an incommunicable art. Yet those who possess originality of mind can be greatly helped by men whose genius lies in this direction, or by their disciples. Still more may they be aided toward the invention of methods and the development of critical power. The higher knowledge, impossible of record, is an oral tradition. Minot received this tradition from H. P. Bowditch, Ranvier, and especially from Ludwig. Of his debt to all three, he was ever conscious. Ludwig he regarded with true veneration. In this, Minot was not alone. The illustrious Heidenhain said at Breslau that the only physiologists who had really accomplished anything were Ludwig and Marey. Ludwig kindled fires in every civilized country. The world owes him a great debt, still unpaid. His extraordinary powers as a ferment were coupled with an engaging simplicity. Shortly before his death, in his seventy-second year, he said: "The pity of it is, I shall have to leave off just when it becomes most interesting." Ludwig gave to Minot the secret of lifelong youth, the reward of those who continually voyage for discovery.

* Read at a meeting of the Boston Society for Medical Improvement, January 25, 1915.

Minot's first physiological work was a research with Professor Bowditch entitled, *The Influence of Anesthetics on the Vasomotor Centres*. It was published in the *BOSTON MEDICAL AND SURGICAL JOURNAL* in 1874, more than forty years ago. The experiments were probably largely by Minot, but the publication itself bears unmistakably the marks of Bowditch's lucid style and careful hand. In this investigation it was shown that "in the majority of cases the rise of blood tension consequent upon irritation of the saphena nerve is less marked when the animal is under the influence of ether or chloroform than when the anesthetics are not used." This result is due to a diminished activity of the vasomotor centre. Changes in the blood pressure were also noted. Ether causes a rise in the blood tension from 9 to 51 mm. of mercury, while chloroform causes a fall of from 8 to 37 mm. The action of chloroform on blood pressure is due in large part to its influence on the vasomotor centre and only in small part to enfeeblement of the heart.

While at Leipzig Dr. Minot worked under Ludwig's direction on the formation of carbon dioxide in resting and active muscle. This work was published in 1876 in the *Arbeiten aus der physiologischen Anstalt zu Leipzig*. An artificial circulation of blood serum was established through the biceps and the semitendinosus femoris at rest and during electrical excitation of the muscles. It was found that the carbon dioxide given off to the circulating serum was not increased by tetanizing the muscles. The conclusion was that carbon dioxide is not a decomposition product of muscular contraction. The methods employed in this investigation, though good for the time, are not altogether free from loopholes, and the conclusion reached is opposed to our present knowledge that the excretion of carbon dioxide is greatly increased by muscular contractions. It is therefore suspected that the carbon dioxide is after all set free in the muscles themselves, but the evidence is not conclusive.

In 1878 Dr. Minot published in the *Journal of Anatomy and Physiology* his experiments on tetanus, made in the Physiological Laboratory of the Harvard Medical School. They showed that when a muscle is forced to contract by a succession of induction shocks, the phenomena are essentially the same whether the interval between two shocks be several seconds or a small fraction of a single second. In other words, the difference between the various forms of muscular contraction depends merely upon the interval between the single shocks and the variations in the rate of the return of the muscle to its original length. This research was ingenious, laborious, meticulous, a conscientious collection of crumbs left by those earlier at the feast. It marks the end of Dr. Minot's first manner.

The paper on muscle contraction, like the two preceding papers, dealt with problems treated from a purely physical standpoint—an index of the times. Johannes Müller, that great genius who is justly called the Father of modern phys-

iology, had begun the good fight to place physiology among the true sciences, to express biological phenomena in grams, centimetres, and seconds. Helmholtz, von Brücke, Ludwig, and DuBois-Reymond completed his work. In my day, as a student in the University of Berlin, the Kneipe in which physiology was given its modern dress was still pointed out to reverent youth. The job was done most thoroughly—so thoroughly that, after a time, the method became somewhat irksome to persons not especially fitted to be sappers and miners. Whether the scholastic excesses of the physical school caused Minot's revolt or whether his apostasy from the rigid sectarianism was a consequence of new studies connected with his appointment to teach histology and embryology in the Harvard Medical School, I will not attempt to say. It is enough to know that he left his foster nurse for what was then called biology, a hybrid of physiology and anatomy, alleged at that time to have inherited the virtues but not the faults of both its parents.

It was a conscious and deliberate revolt. In that same year, 1890, he thus exalts the Egeria of his choice: "We should not study merely the organs of the body, whether in their anatomical or their functional relations. There are persons who never understand the arrangement which Nature has established. We are always separating things from their natural connection and taking up a special series of views, instead of more general ones. There is in the direction of true *general* biology, a vast opportunity which I hope will soon be generously taken advantage of. There are many things which we can hope to understand only when study is prosecuted from that point of view. All of the important phenomena of reproduction, of heredity, of the evolution of species, and of all the relations of actual organisms to the general economy of nature, of sex, of growth and variation, even of death itself, which is a problem I believe capable of scientific solution;—all these things are hidden away to a large extent from the morphologist and the physiologist, they are open to the general biologist." (*American Association for the Advancement of Science*, 1890, xxxix, p. 18.)

It is enough to say that this belief in the perfectibility of the very human biologist has not yet been realized. The hope was common in those days. The history of thought is strewn with broken dreams. They rise like the mirage. The weary traveller, toiling through arid facts, as numerous and as unrelated as the sands of the Sahara, sees afar off the shining lakes of Theory. There, on the horizon, is that which shall fit the desert to be the abode of men. The traveller presses on. The mirage dissolves, and from afar the sphinx, inscrutable, looks down upon the immemorial sand. The biologist may dress himself tastefully in the plumage of the physiologist and the anatomist, but this will not create him a new species. Dr. Minot remained essentially a physiologist all his life, though, like many physiologists, he worked from time to time on structure.

His devotion to morphology had probably a deeper source than his special chair in Harvard University. In his youth, the stamp of Ludwig's genius gave his mind a lasting impression. Many years after the Leipzig days, Minot, in a public letter to Mosso, declared that from Ludwig he "had learned to regard the living organism as an apparatus, of which it was necessary to learn both the construction and the working, and always to seek the explanation of the working on the basis of the construction." In Ludwig's generation this passed for truth. So artists once painted portraits by drawing the features and afterwards coloring them. They did not know that the lines of a face are not lines, but the edges of fields of light. Vermeer marks the eye by a clear light upon the lid and a patch of shadow beneath it. The eye is there in unsurpassed perfection and not a line is drawn. Experience has shown that structure is an unsafe guide to function. Anatomy led the infant physiology by the hand and taught the gifted child some lessons that did not stand the test of experience. It was from the anatomist, for example, that physiologists got the notion that the respiratory centre must be a circumscribed group of nerve cells like the nucleus of the hypoglossus. Eight physiologists found this centre each in a different part of the bulb. Later investigators removed each of these centres, but respiration still went on. So it was proved that a community of function may exist in widely separated cells. A physiological centre may or may not be a group of cells closely related in space; it need only be a group closely related in function. But Ludwig's view was orthodox in his day, and powerfully influenced his disciples.

We suspect that in his heart Dr. Minot concealed a regret that he could not become a philosopher. In his letter to Mosso he says: "The agnostic position is the only possible and defensible one for a scientific man to occupy, who is loyal to the spirit of research.—No hypothesis of life yet offered requires serious scientific consideration. A confession of agnosticism is here a positive contribution to the truth. On the other hand, there is no reason for giving up the endeavor to get nearer to the final goal of biology because attempts to reach it by the short cut of speculation have always failed."

He was we perceive, wise enough to bind himself fast to the mast of demonstrable fact, before he listened to the ravishing song of the sirens of philosophy. There is a brave optimism in his search for an answer to the problem of life. We applaud the bold adventurer the more, because he has set his face against the disheartening conclusion that there is, at present, perhaps no logical hope that the Grail of physiological science can ever be found. The physiologist who seeks the key of life must proceed from established premises. The established data show that the biological scene is a succession of permutations, of momentary equilibriums, of resultants ex-

pressing the interaction of a multitude of factors. But as soon as the individual factors rise above a number so small as to constitute the major criticism upon our petty minds—we speak of chance. It is probable that the riddle of existence will never be solved, because the factors and their possible interactions exceed the apparatus for their detection. No mental gifts will ever make us hear the high-pitched sounds audible to insects, nor shall we ever listen to the music of the spheres.

Dr. Minot began his new scientific life by a study of growth, senescence, and death, subjects which occupied him for thirty years. Very likely he was first attracted to this field by the memorable researches of Dr. Bowditch on the growth of children. Dr. Bowditch often lamented that measurements of children in statistical quantities could hardly be obtained before and after the school age. Nor was it possible to follow month by month the growth of thousands of individuals from birth to maturity. Dr. Minot determined therefore to study growth as a function of age in one of the higher vertebrates other than man. His observations were begun in the physiological laboratory of the Harvard Medical School about 1885. Hundreds of guinea-pigs were weighed every day from birth up to 40 days, then every fifth day up to 215 days, then three times a month to the end of the second year after birth. Most of the results of this great task were published in 1891, in the English *Journal of Physiology*. One of the most important fruits of these studies was the recognition of a new and more accurate method of expressing growth. All previous investigators had figured the absolute rate of growth, i.e. the growth of a child in any one year was the number of pounds gained in that year. Minot points out that five pounds gained by a small child is a greater gain than five pounds gained by a large child. The true rate of growth, he very rightly insists, is expressed by the relation between the growth in any one year and the weight at the beginning of that year. This is Minot's percentile rate of growth.

The principal fact developed in the paper of 1891 was that there is in guinea-pigs a progressive loss in the power of growth, extraordinarily rapid in the early hours of life. In the first forty-five days the ability to grow decreases four-fifths.

The work with guinea-pigs was followed by valuable studies on intra-uterine growth.

Eighteen years after his first publication on growth Dr. Minot summed up his studies in this direction in a book entitled *Age, Growth, and Death*. Here he demonstrates that the rate of growth is highest at segmentation and from that hour declines, at first with great rapidity and then more slowly. The period of most rapid decline is youth; the period of slowest decline is old age. If we consider death to be the bankruptcy of an organism which spends energy beyond its income, the final dissolution is almost

complete before the highly efficient life in the womb is exchanged for that in a much less favorable environment. The paradoxes demonstrated as truths by Dr. Minot's work show us how far from correct are the conventional ideas of life. Birth and death, the accumulation and the discharge of energy, go on unceasingly side by side. There are no terminal stations. Energy is a stream that empties into its source, and life is a function of time.

The book on Age, Growth, and Death treats also of Dr. Minot's views, first expressed in 1890, regarding the increase in the amount of protoplasm within the limits of single cells. By the study of the proportionate volumes of the nucleus and the cell body, he believed he could demonstrate certain laws governing that proportion, and prove that the variations of the proportion establish conditions which are fundamental to the correct conception of growth, differentiation, death, and sex. The most characteristic peculiarity of advancing age, of increasing development, is, in Dr. Minot's opinion, the relative growth of protoplasm. The possession of a large relative quantity of protoplasm is a sign of age. It is essential to rapid growth that the proportion of protoplasm should be small. The development of protoplasm, Dr. Minot taught, is the cause of the loss of power of growth.

It will be observed that this stimulating but incomplete list of Dr. Minot's services to physiology touches but one side of his activity. I have not spoken of his many valuable contributions to morphology, of his text-books, the first of which, especially, much enlarged the influence of the young science of embryology; of his admirable addresses at scientific meetings nor of his ingenious inventions such as the rocking microtome. Time does not serve, nor can one man speak with authority of services in so many fields. Perhaps the highest praise a man can have, is that his biography must be written by a company rather than by a single individual.

It remains to speak of Dr. Minot as a friend. But of his friendship and our personal relations I cannot trust myself to speak. He shone brightest in the adversity of his friends, both by his resolute bearing toward opponents and by his counsel. Of all the words I was privileged to have from him, I best remember his saying that a scientist should never consult his personal happiness and that injuries were best forgiven and forgotten.

I believe that Charles Sedgwick Minot, the friend, the comrade, the distinguished scientist in whose honor we are met, will be in death as in life a staff for the weak, a mark for the strong, a light to guide and cheer despondent men. The weak will see in him a triumph over circumstance; the strong will draw new strength from his unrenitting years of high endeavor; and the despondent, averting their sad eyes from the fields on which so many of our ideals have lately fallen, will find in his career fresh hope

and a renewed belief that life is after all worth living.

JAMES GREGORY MUMFORD, M.D.*

BY RICHARD C. CABOT, M.D., BOSTON.

AMONG those who knew James Gregory Mumford and realized his physical limitations, it has become a familiar miracle,—how he accomplished the enormous and varied work which stands today to his credit. But when one looks back over the remembrances of many years and pictures the man,—his looks, his voice, his manner, his build,—the victory over his own temperament seems even more remarkable than his conquest of physical handicaps. He was a reformer yet without many of the reformer's natural attributes. Of the reformer's traditional buoyancy and high spirits, he had not a trace. He was never buoyant or spontaneously expansive. He did not bubble over. He had none of the qualities of a steam roller; yet he was always pressing relentlessly on. He was thin-skinned, sensitive, shy and modest, yet he set himself to push through obstacles that would tear the average man to pieces.

Reformers are usually cock sure. Mumford was never so. He had almost an ironic consciousness of human fallibility,—in himself most of all. His plans and achievements never swept him away. He was their impelling force himself. In a letter written in 1910 to the secretary of his college class, he portrays his work without any of the reformer's ardor and confidence.

"So the simple record runs on," he says, "telling of mild employments in the Harvard Medical School and elsewhere. I like teaching; students pass me out the usual compliments due to credulous senility. (He was 47 when he thus described himself.) I like practising surgery; patients toss me roses mingled with thorns. I like writing about people and things, for the reviewers deal me comments which chasten the soul. Altogether, life continues a pleasant experience. I look forward with composure to the next twenty-five years."

Anyone who did not know his arduous achievements, his daring ideals, his ever-renewed battle with fate and conservatism, might gather from words like these,—indeed from most of his writings,—that he took life easily, smilingly, indulgently. His style has often the light, whimsical quality of one who looks on with tolerance and amusement at the crusading reformers. Yet he was himself a crusader and a reformer. His life never mirrored the easy-chair quality of his style; perhaps it was his way of resting from the sterner efforts of his medical career.

He had the look and manner of a recluse and I doubt if he was ever happier than when alone with his wife in the woods or by his library fire.

* Read at a meeting of the Boston Society for Medical Improvement, January 25, 1915.

The retiring, sensitive side of his nature must have shrunk even more than the average man's from the buffets of a reformer's existence. No one could have felt more keenly than he, for example, the crushing weight of newspaper criticism by medical colleagues, as for example at the time of his connection with the Medical Advisory Board of Emmanuel Church. For he did not love a fight. There was none of the glow of battle in his face. His convictions had not that tough, resistant consistency that makes some of us the surer that we are right when every one yells that we are wrong.

In this paradox we face the central mystery of his life. His was a fighting recluse, a sensitive militant, a shy reformer, a private spirited publicist, a tender footed pioneer. All this was especially marked in his later years. In school and college, the rift in his nature was less visible. It was then his scholarly and refined tastes, not his pioneering spirit, that impressed his friends. Yet his life-long conscientiousness is exemplified in the earliest of all the stories told of him. He was born in 1863. In 1867, when on a drive with his aunt in Rochester, he was shocked to see from the height of his four years of earthly experience, a clothes line still heavy with the week's washing, though the week was nearly over. "What! Friday, and the wash not yet done!"

That conscience,—a New York conscience, not a New England one by the way,—is, I take it, the key to unlock the mystery of his life. Conscience, not buoyancy, made him optimistic. Conscience, not fervor, pushed forward his reforms. Conscience is written into every entry of the journal where in 1879 he listed the books on the shelves of his first library at St. Paul's school. The handwriting is remarkably concise and neat for a boy of fourteen. This book list includes Mommsen, Thackeray, most of the English and American poets, Shakespeare, a good many books of travel, five volumes of the *Lives of Engineers* and a few modern novels. We cannot be sure that he had read them all, but many of them had been lent by him to other boys whose names, with the dates when they took and returned the books, are methodically recorded. I think a boy is more likely to have read the books that he lends,—especially when the boy is Jim Mumford.

This bookishness remained with him and grew with his growth from the passive to the active or creative mood. The list of his writings is impressive, even from its size.

Eight books,* aggregating nearly 3500 pages, came from his hand within twelve years, and during a slightly longer period, sixty articles in

medical journals. Many of these articles, such as that analysing 300 skull fractures, represented much labor. But the quality and style of this voluminous output makes it far more impressive. Mumford was one of the three or four American medical writers who has seriously tried to write good English. The German method of dumping words in piles upon a page and leaving the reader to deal with them as best he may, is that followed by practically all contemporary writers of American medicine. But this method never appealed to Mumford, who had left behind school-boy English before he left school, and ever after labored to make his writings justify the education which he had received.

As he was the only Bostonian who has ever produced a text-book on surgery, and as the current of his interests flowed strongly towards teaching, it can hardly have failed to be a disappointment to him that he never advanced beyond the rank of instructor at the Harvard Medical School.

But it is doubtful whether he would ever have desired to occupy the office of a professor of surgery, so long as that office remained what it was and still is. As early as 1906, nearly ten years ago, he foresaw the need of a surgical professor who should devote himself like other professors to his office. That a professor should never be obliged to devote a large proportion of his time to private practice in order to make a living, that he should not teach for a merely nominal salary and should give but a small part of his time to teaching or study, is now so generally realized that the anomaly will soon, I believe, be remedied in the Harvard Medical School. But in 1906,—nine years ago,—there were few who dared to hope for such a high standard of instruction. The amateur clinical teacher was the accepted and inevitable portion of every medical school but one in the country. That he saw years before the rest of us the step that medical teaching would take next, by making clinical professors full-time men, was entirely characteristic of the man. We shall find it true in all the great interests of his life.

One of those interests was religion. He was old-fashioned enough to believe in God, in marriage and in other eternal truths to which the excesses of modern enlightenment have for the time very generally blinded our eyes. He believed that the human body in sickness and in health is usually inhabited by a soul, and he cherished the still more unpopular belief that a man's soul may conceivably be as well known to a clergyman who had given it his life-long study as to a doctor who has studied it but fitfully and as a secondary interest. Believing this, he thought it not impossible that a clergyman might help a doctor. He never believed that a clergyman should practice medicine but he was firmly convinced that a doctor should not delude himself with the belief that he owns his patient. That the two professions could work

He was also in editorial charge of the *History of the Harvard Medical School* (3 vols.) written by Dr. Thos. F. Harrington.

simultaneously for one patient's good was the belief underlying what was called some years ago the Emmanuel movement. Like Elwood Worcester, the leader of this movement, Mumford hoped that the doctors would be convinced of this. But they remained unconvinced and as a piece of genuine, widespread and whole-hearted coöperation between minister and doctor, the attempt failed, because the doctors, as a rule, had a low opinion of the ministers.

Nevertheless, I have no doubt that in this, as in his other hopes, Mumford was ahead of his age, in 1908-9, not behind it, and that in some form, his attempt will yet succeed.

Coöperation between doctor and minister was the ideal of this lost cause,—coöperation was also the key note of the next reform which in 1910 Dr. Mumford tried to effect. The Emergency Hospital (now Grace Hospital) on Kingston street, was then in the market. This hospital had always been managed upon a partially coöperative basis. That is, people paid a small fee yearly for treatment there and the physicians attached to it were supposed to get their living—in part at least—out of these fees. Mumford believed that, although faulty in execution, this plan marked out in essentials the right way to support a hospital and to get adequate treatment for the vast number of people of moderate means who now get the worst medical and surgical treatment that a civilized community permits. He wanted to supply the needs of those who will not go to a free hospital clinic or who are refused admittance there, but who are still unable to pay the high prices which accurate diagnosis and rational treatment necessitate. He knew that the poor who visit free hospital clinics are now getting better treatment than any but the very rich. He wanted to bring good medical service within the reach of every one.

To do this he proposed that the old Emergency Hospital should be secured; that a prospectus should be issued explaining the plan of a coöperative hospital, of which he was to be the surgical head and I the medical head. Each of us was to organize a staff of physicians to do under our supervision the work of the hospital and to be paid out of the fees of subscribers who were to contribute so much a year for the right to be treated there without further charge. Dr. Mumford believed that with adequate laboratories and x-ray outfits, with a proper system of group diagnosis by a combination of men, each expert in his own field, and by furnishing to every patient the degree of sympathy, courtesy and consideration now given by the private physician and omitted in most free clinics, the hospital could be made so attractive that it would pay. Science and sympathy he believed could be combined and, by proper organization at a hospital, could be made available for every one at a low price, while yet providing good salaries for the physicians.

Some form of coöperation both with the ministers of religion and with social service workers

he also hoped to bring about at the new hospital. In short, all that we both had failed to accomplish elsewhere, we hoped here to attain. The plan was wholly his and had it succeeded the credit would have been wholly his. We got as far as a typewritten prospectus,—written by him. Then the scheme fell through for lack of funds.

I have told of this plan in detail because, though it came to nothing in Boston, it was undoubtedly a precursor in Dr. Mumford's mind of his Clifton Springs undertaking. Hopes nourished during the time when he was trying to figure out the Coöperative Hospital on Kingston street took a further lease of life when it was proposed to him to become Physician-in-Chief of the Clifton Springs Sanitarium.

That title deserves a moment's notice. Not surgeon-in-chief but physician-in-chief was the name of his office. As head of the institution, he succeeded Dr. Charles P. Emerson, an internist. This he was perfectly fit to do because of his long experience of general medical practice during his summers at Nahant. For 12 years, from 1894 to 1906, he spent nearly half of each year in general family practice, including in the earlier years, very little surgery. This broad and varied experience prepared him to be the Physician-in-Chief of an institution where surgery was by no means the central interest.

"I've agreed to take this big institution," he writes in August, 1912, "and build it up, getting together a high-grade staff and other trifles. There's a great opportunity, great interest and great promise. I shall not be cut off from Boston. I am retaining a surgical lectureship in the University and shall come each year to give a course or courses. I am feeling well and chipper." This was scarcely six months after his second serious breakdown, an attack from his life long enemy, rheumatic heart trouble, which two years later cost him his life. With the irrepressible hopefulness that had been but temporarily checked by the failure of the coöperative hospital scheme in Boston, he plunged into his last and best crusade, the attempt to make out of Clifton Sanitarium a great coöperative medical and surgical institution. Despite the splendid leadership of his predecessor, Dr. C. P. Emerson, the staff had not been thoroughly reorganized, so that Dr. Emerson's new methods had not been able to permeate and reinvigorate the old institution. It had remained a place where people went to rest and sometimes stayed to rest indefinitely. Mumford began to make of it an active institution where people could be treated and put back into the world fit to work.

Under his inspiring leadership a splendid body of young physicians and surgeons was rapidly being accumulated and the methods and standards of the place were being modernized, when a difference of policy between Dr. Mumford and the financial heads of the institution led to his resignation, very shortly before his death.

As we look back over this record of Dr. Mumford's, we might well interpret it as one devoted to lost causes. He did not see established at Harvard such a full time Professorship of Clinical Surgery as he might well have aspired to fill. He did not live to see that closer coöperation of doctor and clergyman for which in the Emmanuel movement he had hoped. In Boston and later in Clifton Springs his eagerness to organize a coöperative hospital, serving the whole public, received a check. Yet he was never and could never have become a disappointed man. He lived by faith and not by sight. He knew that the reforms he fought for must come to pass sooner or later. He bequeathed his unfinished task to us. We have taken from his hands the tools he was forced to lay down. Two, at any rate, of the three medical reforms for which he lived and died,—full time clinical professorships and a medical clinic where every one, no matter how rich or how poor, can be treated by physicians paid out of the fees thus collected,—these two reforms I believe we shall see carried out here in Boston within the next few years. That is what he most wanted,—the goal itself, not his personal share in it. He ran his distance and passed on his message to us.

We are here to commemorate James Gregory Mumford. The sincerity of that intention will be manifest when we dedicate ourselves afresh to the task for which he gave "the last full measure of devotion" when we "here highly resolve that he shall not have died in vain." To us is bequeathed the task he left unfinished, that his ideal of medical service organized by the medical profession for all the people shall be made a reality in America.

THE CHANGED POSITION OF THE PROFESSION OF MEDICINE.

BY DAVID W. CHEEVER, M.D., BOSTON.

HAVING begun the study of medicine in 1854, and its practice in 1858, I can look back over sixty years of medical events; besides this, being descended from two generations of doctors, medical influences surrounded me from childhood. I therefore feel that I am qualified to survey all this period, while excusing myself from too much egotism. Two great changes in medicine will naturally occur to everyone, namely, anesthesia and asepsis. These, however, I do not feel it necessary to detail, but shall confine myself to two classes of influences, one external or arising from outward circumstances, the other originated by the doctor himself. Naturally we must consider the external

circumstances first; but before doing so, it will be useful to glance at the real condition of the medical profession in my childhood.

Active interference with disease and the use of strong remedies were in vogue. Deadly mineral poisons, such as antimony, mercury, and lead, were largely used. Emetics, now rarely used, were habitually employed, and sometimes, I think, with benefit. There was a strong feeling that unhealthy influences could be expelled from the body by purgatives. These were freely and frequently used. It was thought that the taking of blood from the body by repeated venesection reduced fever and led to the generation of a new and better blood. It was an old-fashioned habit with a good many people of adult or middle age to be bled once a year, whether sick or not, as a sanitary measure. My father bled people. I myself have sometimes bled patients by venesection, and in properly selected cases I am convinced it is a remedy of value. All sorts of spring medicine, or "spring cleansing" as I call it, were popular, and they are popular still. The other remedies mentioned have mostly fallen into disuse. It thus can be shown that the medical mind, and hence the popular mind, were very much in favor of considering disease as an entity, which could be "knocked out," so to speak, by a sharp counter-blow given by the doctor.

Under these circumstances, about the year 1850—I cannot be precise—there arose a great medical doubt. Sir John Forbes in England, Dr. Jacob Bigelow and Dr. O. W. Holmes in America, enunciated a new theory, as follows: that all diseases were self-limited, having a natural rise, progress and decline, and hence were little influenced by medicine. If this were true, it naturally followed that it was the best policy for the doctor to care for the patient by watching his symptoms rather than by using very active medication of uncertain power. From this arose what was called Expectant Treatment: to wait on Nature; to be sure to do no harm, if you could do no good.

I must be allowed to return a moment to myself. I did not seriously study medicine until I was twenty-three years old. I was fairly mature; I had had large collateral reading; I absorbed these doctrines and I wrote them up in the *North American Review* and in a Prize Essay. I entered upon the study of medicine with an intensity which proved that I had chosen the right calling. These nullifying doctrines had a very depressing effect on me. What was the use of practising an art which could promise so little? I almost felt tempted to give up my profession. Fortunately for me, I was led to continue the study and teaching of anatomy for eight years, and thus passed on to the pursuit of surgery, where I found solid ground. As time went on, like all other doctors of my time, I did practise medicine as well as surgery. Experience taught me that the doctrine of self-limited disease was

not all true, that there was something in drugs; on some I learned to rely; and I still believe they are useful.

All this personal digression is for the purpose of trying to bring before the reader the exact condition of medical practice about fifty years ago. We are now ready to consider those influences which changed medicine, arising from without. And the first of these is Homeopathy.

This novel and peculiar belief, "made in Germany," never attained its full vigor in the land of its birth; prevailed very moderately in France, but to a greater extent in England. It received, however, a prompt recognition among certain of the more educated classes in this country and attained here an exotic growth; following soon after the introduction of the speculative views of German philosophy, it seemed to some to ally itself with them and to be a new advance in reasoning. It had two dogmas: one that the strength of medicines was increased by minute division and sub-division; the other that if a drug taken in health produced certain symptoms, it would affect or cure any diseased condition which was characterized by like symptoms. Those who professed this method necessarily rejected the older methods which opposed it. Hence the physician who was old-fashioned or regular rejected this belief as an exclusive and one-sided dogma which denied all other things which he believed true; and as these new views were diametrically opposed to his own as to the *treatment* of the sick, he was consistent in refusing a consultation with the homeopathic doctor, because it could do no good. This new practice attracted many people from the better classes and proportionately diminished the *clientèle* of the regular doctor. Homeopathy for some years increased, founded schools, endowed hospitals, established medical societies, divided the public into sects of medical belief. As time wore on, it grew less distinctive, and the methods of old or regular practice supplanted it to a large extent.

Meanwhile another new belief in healing, of a semi-religious character, calling itself Christian Science, or Mental Healing, arose. Its doctrine was that the will could control organic processes either wholly or to a much greater degree than had previously been supposed. It encouraged all weakly people to try to get well by themselves; and to a certain degree its influence was salutary. But when it undertook to cope with acute or contagious disease or to seek to control the heart, the stomach, the bowels, the uterus, which were constituted by nature, and purposely so, to be beyond the influence of the will, it failed. The bacteria of diphtheria, unrestrained by Christian Science, were diffused among other members of a family; pneumonia was encouraged to will to be well, and the patient sometimes, rashly exerting himself, hastened a fatal result; the retained secundines

at childbirth destroyed the patient by a fatal flooding, when the will-power failed, as it must fail, to contract the uterus. The mixture of religious belief with these medical theories influenced and attracted very many people, and are still in our own day an obstacle to medical practice, although the brilliant advance of medicine in laboratory methods, making our profession a new science, will gradually overcome them.

The next change in the last half-century was the entrance of women into the medical profession. The new woman, emerging from the seclusion of inherited Puritanism, now demanded admission into our ranks. The regular physicians hesitated to admit her claims for two reasons: first, that her presence at medical meetings would interfere with freedom of discussion; second, that many patients of either sex would object to being examined in detail in the presence of both sexes, and that to render such a patient unconscious by anesthesia and then submit him or her to such an examination was unfair. These fears have proved to be well-founded. However, women have freely entered the medical profession; and practise, so far as I know, every form of surgery, as well as medicine and obstetrics. It must be conceded, however, that their services are largely limited to their own sex.

An important influence on the *materia medica* employed by the physician was now exerted by the enormous advance in chemistry. We can almost say that it has revolutionized the relation of the druggist to the doctor. The latter had relied on a druggist of repute to select pure drugs and to compound them under the doctor's direction by the so-called prescription. The relations of doctor and druggist were thus intimate; each relied on the other. But now new modes of manufacture and new remedies made by synthetic chemistry have taken the place of many of the old tinctures and pills. As another instance, the extraction of alkaloids, or the active principle of drugs, has furnished concentrated remedies in minute and cleanly form; these alkaloids are also indispensable in the subcutaneous administration of remedies. Being more palatable, the new medicines furnished by chemistry are more sought after by the public; thus they have contributed to enlarge the use of proprietary medicines to the detriment of the ignorant; the abuse of narcotics is thus partially to be explained. It is fair to consider, however, that the supposed purity of materials and the supposed accuracy of manufacture depend upon the reputation of the manufacturing chemist.

Finally, among external influences, the growth of hospitals has been the most potent of all in changing the practice of medicine. Half a century ago, there was but one large hospital in Boston. Through its influence, it came to pass that, since no fees were allowed to be

charged by its physicians and surgeons for the care of its inmates, whether rich or poor, some of its medical staff established a private hospital, in which they could receive remuneration for their services. I mean to say that this was a local influence. General influences, however, were abroad in all communities, which led to a demand for, and the increase of, hospitals of every grade. We might say that the hospital has become universal, much to the detriment of the medical profession pecuniarily, for there is often an abuse of charity, since others than the poor habitually seek the hospital, and deprive the doctor of his pay. This is especially the case among those who come and go daily in the out-patient departments. But in the wards also there are occasionally wealthy patients, some of whom would wish to pay, while others seek to escape any such obligation. The majority of doctors are placed somewhat at a disadvantage by the abundance of hospitals, and perhaps in comparative reputation with the physicians who hold positions in them. Today even moderate communities have their hospitals; cities many, towns or villages one. It must thus be evident that the private physician, surgeon, and even specialist have the amount of their business decreased and their earning capacity limited by hospitals. It is not necessary here to discuss whether the public are not benefited by the hospitals; I confine myself to their influence on the profession of medicine.

This completes my enumeration of the external circumstances which have influenced the profession of medicine, and we now turn to those changes which physicians have brought about themselves. Fifty years ago Specialism was almost unknown and was limited to the special senses, as the eye or ear. Gradually specialties have increased more and more, until now their divisions and subdivisions are so minute as to be bounded by a single organ. The specialist justifies his position by saying that he knows more on any single subject by confining himself to it. The family practitioner, however, urges that the specialist loses that full consideration of the general well-being of the patient which he himself acquires. It is certainly unfortunate that the doctor does not have now the whole of his patient, and that the patient does not have an individual doctor. A large family, the members of which one general practitioner formerly took care of, knowing by experience their heredity, their tendencies, their habits, now seeks the advice of four or five specialists. Apart from other considerations, expenses are thus increased; for the specialist, having fewer patients and fewer calls for his services, is justified in charging larger fees.

This leads us to say a word of what has been called Commercialism in medicine. This I understand to mean thinking more of the fee than

the patient and charging all that the patient can pay. I wish it distinctly understood that no one is more particular than myself in charging fees to patients who are able to pay, provided such fees are reasonable, and we must all agree that the very rich man or one of social prominence should be charged more for skilful service than his neighbor of limited means. But very large sums claimed as a return for professional services have, as I believe, injured the reputation of the profession. The scandal of the "split fee" I have never personally met with.

The next change created by the physicians themselves is Publicity. The reticence of the doctor was formerly proverbial. It was not deemed wise to tell the patient too much. Every medical utterance has an exaggerated importance, and an opinion too freely imparted worries and depresses the patient. So also it used to be thought that to take the public into your confidence and to communicate the "little knowledge which is a dangerous thing" was injurious; that people got false ideas and went astray; and that, on the whole, more harm than good was done. Now all this is changed. However, when public medical lectures are confined to carefully selected subjects and limited to hygienic measures, they may be useful.

Medicine has been advanced to approximate a Science by Laboratory methods. These methods have supplanted the guess-work of earlier diagnosis. They are invaluable; they have been produced gradually by patient investigation and self-sacrificing and sometimes dangerous labors; and they have come to stay. They are the first line of defence against delusion and superstition in medicine. Moreover, they have given us Preventive Medicine. In my earlier days there was but one disease which could be surely averted, and that was smallpox by the use of vaccination. Now the discovery of serum-therapy and the injection of anti-toxins control diphtheria, temporarily control typhoid, and offer great hope in the treatment of meningitis, tetanus, rabies, and some other diseases still under investigation. No greater change in the practice of medicine could be imagined.

Finally, the Trained Nurse was introduced among the sick by the doctor himself, first, in hospitals, as was natural, then in private life. She is a great help to the doctor; she relieves him of drudgery; she lessens his anxiety; she should be his executive assistant, and not aspire to be his partner. She should be modest in her *dicta*, for her opinion is constantly sought and carries weight. While in acute disease her full fees are no more than they should be, yet in cases of long illness some means will eventually be found by which the very heavy expense of her service may be diminished.

THE MENACE OF SYPHILIS TO THE CLEAN LIVING PUBLIC.

BY J. HARPER BLAISDELL, M.D., BOSTON,

Physician, Skin Department, Boston Dispensary; Dermatologist, Lynn Hospital; Assistant, Skin Department, Massachusetts General Hospital.

[From the Records of the Skin Department of the Boston Dispensary.]

EVERY community is divided into two classes of individuals,—those who have syphilis and those who are exposed to it. Medical science and lay interests have been focussed upon the diagnosis and successful treatment of the disease in those afflicted with it to the practically total exclusion of the now greater problem of the rights and protection of those who may be exposed to it.

Two factors enter largely into the present indifference on the part of the physician and layman alike to the relation of this disease to public health. One is the fact that syphilis has been and always will be closely identified with immoral sexual relations. The acquisition of the disease is felt to be but a just punishment for the mis-deeds of its possessor. Blinded by the venereal aspect little thought has been given to the question of how active a menace it may be as an infectious disease to the general clean living public.

The second factor making for indifference is that we are absolutely ignorant as to the prevalence of the disease with which we are fighting. An approximate number even of those having the disease in this Commonwealth is absolutely unknown. Opinions among the medical profession are at the widest variance. One extremist takes the lofty attitude that such a disease cannot be present among the high-class clientele that he may have. Otherwise broad-minded physicians frequently rule out the disease for no better reason than "I have known the family

for years." The other extremist sees the spirochete at the bottom of every puzzling case.

For several years past syphilis has been made a reportable disease by the City of New York and the figures reported by the health authorities there probably represent as accurate an estimate of the amount of the disease in a given community as any now available. During the fourteen weeks from July 4th to October 3d, 1914, 25,633 infectious and contagious diseases were reported in the City of New York with a population of a little over five and one-half millions. Syphilis stood first in the list with 6342 cases or 28%; tuberculosis second, 5525 cases or 21%; diphtheria third, 3370 cases or 13%; measles fourth, 2750 cases or 11%; scarlet fever fifth, 1064 cases or 4%. Figures like these bespeak for themselves the urgent necessity of establishing regulations for the control of those having the disease and for the protection of the community.

For the purpose of finding out how definite a menace individual cases of syphilis may be to the community, sixty cases in the early stages were selected as they happened to come to the Skin department of the Boston Dispensary and the relation of their infectiousness to their associates studied. The tabulations include sex, age, marital relation, occupation, duration of the disease in weeks, presenting symptoms, methods of living and eating, the number of persons exposed through coitus since infection, the number definitely exposed through family life or association in boarding houses, the number of co-workers exposed, and the number of known infections from the case in hand. The co-workers' exposure column includes only those that came in active contact with the infected person through toilets, drinking facilities, etc. No attempt was made to record the number of persons exposed by casual contact as for instance, —eating in the same restaurant, being waited on in a store, or consuming food products handled by the infected person. The table in full with a more detailed explanation of some of the more striking cases is as follows:

Case No.	Sex.	Age.	S. M. W. D.	Work.	Dur. in Wks.	Symptoms.	Method of Living.	Method of Eating.	Coitus.	Family or Boarders.	Co-workers.	Known Infections.

CASE 6. Married woman. Husband away for six months at a time. Five children from ages of six to twenty at home. Earned extra money by immoral life in flat up-stairs kept by a professional.

CASE 7. Poverty stricken woman of subnormal intelligence living on charity and occasional immoral earnings.

CASE 8. Girl of good family with primary of lip of unknown origin. Was having occasional intercourse with fiancé who neither had nor contracted syphilis.

CASE 9. Typical "tough" girl working in a candy factory who is in the habit of having promiscuous intercourse with her male friends. Two of them not recorded in this series, were infected.

CASE 10. Waitress in a well known restaurant with very active and infectious syphilis.

CASE 14. Italian laborer, sleeping with another man, who planned to return to his wife and two children in Italy within two months. I know of two other similar cases not recorded in this series.

CASE 21. Woman with active mouth lesions of syphilis, who worked in a candy factory. Had two small children, a husband and a lover.

CASE 22. Actor in a musical comedy show with a primary of the lip and mucous patches who was in the habit of kissing many of the chorus girls frequently.

CASE 27. High class nurse in a doctor's family. Had active secondaries before the trouble was discovered. Had complete charge of two small children and was treated as one of the family, eating at the same table, using the bath-room, etc.

CASE 31. Woman with very active syphilis and several "friends," who infected her two-year old baby with a primary of the forehead, presumably from kissing.

CASE 35. Cook in a dairy lunch place with a primary of the finger and extremely active secondary lesions of many weeks' duration. This man handled all the food, drinking glasses, dishes, etc., of a great many people daily. His infection prob-

ably came from some dish or glass used by a syphilitic. This case was so extreme as to necessitate its being sent to the State Hospital.

CASE 38. Young woman with active mouth lesions eating in the dining room of a local Y. W. C. A.

CASE 39. Drug clerk with active lesions who served many sodas daily.

CASE 44. Fruit pedlar who had relations with many girls to within one week of marriage. Wife showed active lesions of syphilis and was pregnant.

CASE 45. Elevator boy with large ulcerative primary of penis. Had had relations with as many as eight girls since date of infection and used toilet in common with about 300 people in the office building.

CASE 58. Professional tattooist following fairs. Denied using saliva in moistening pigments altho knew of its being done.

CASE 59. Teamster with primary and all the secondary manifestations living at home with his wife and two small children. He could not be prevailed upon to bring them in for examination and the case was soon lost sight of.

CASE 60. Woman lodging-house keeper with a primary of the tonsil. One of the servants in the house had syphilis, according to the boarders. Woman had a fiancé with whom she had been in the habit of having occasional intercourse during the past year. The fiancé denied all syphilis and married the woman two weeks after the diagnosis was made, as they had originally planned before the primary appeared. The case dropped from the clinic and the source of the syphilis was never determined.

These sixty cases definitely exposed through coitus from the time of their infection to their first appearance in the clinic for treatment one hundred and thirty-four (134) people. Four hundred and forty-two (442) others were coming in contact with them in the intimacies of family or boarding-house life. Six hundred and fifty-one (651) fellow workers had been brought in contact with them sufficiently to run a definite danger of contracting the disease.

Of these sixty cases 41 were men and 19 were women. There were four extra-genital and presumably "innocent" primaries, the number being evenly divided between the sexes. One wife contracted the disease from her husband and five girls were infected by their fiancés. Thirty-nine of the men and eleven of the women acquired the disease in distinctly immoral ways.

The ages of the patients show how closely the disease is associated with young adults. The youngest patient was 16, the oldest 48. Eight men and five women contracted the disease under 20 years, seventeen men and six women between 20 and 25, ten men and two women between 25 and 30, and six men and six women after their thirtieth year.

The course of every infectious disease may

be diagrammatically represented by three links of a chain. The patient at hand corresponds to the middle links, with the source of his infection being the first link, and those to whom he passes the disease being the third. The stamping out of the disease depends as much upon the prompt discovery and control of his source and the prevention of his possible exposure of others as upon the proper medical care of the patient himself. Generally speaking, either in hospital or private practice, little effort is being made along this line. This series strikingly shows the extent of the present neglect and how vast a field of preventive medicine is still untouched.

These sixty cases of fresh untreated syphilis are the direct result of sixty other definitely active foci of infection in the community. Out of these sixty foci only two were brought under medical care and control. Of the 576 people exposed through coitus or family life five were known to have been infected,—four through intercourse and one by being kissed by the mother. Of the 571 equally possible infections nothing is known.

The danger of syphilis to the community as well as to the individual is increased in proportion to the inadequacy of the treatment received by those suffering from the disease. For the purpose of finding out how great a menace syphilitic patients are to themselves and their fellow-beings through neglected treatment a careful statistical investigation of this portion of the clinic was made in order to find out how effectively patients follow their doctors' advice.

Every visit of every new syphilitic patient entering during the twelve months beginning July 1, 1913, has been tabulated from the date of entrance to September 1, 1914. The amount of time which the patients might have been under treatment varies from fourteen months for those who entered in July, 1913, to three months for those coming to the clinic last June. The table showing the number of visits that the patients of the various months of entrance made is as follows:

No. Visits.	July-Dec. Total.	Per Cent.	Jan.-July Total.	Per Cent.	Grand Total.	Grand Total. Per Cent.
1	68	.272	58	.288	126	.280
2	38	.152	33	.164	71	.158
3	31	.124	28	.136	59	.130
4	32	.128	21	.119	56	.121
5	18	.072	18	.090	36	.080
6	12	.048	10	.049	22	.048
7	10	.040	11	.070	21	.051
8	8	.032	8	.039	16	.036
9-15	25	.132	8	.045	33	.090
16-23	8		0		8	
Total	250	1.000	201	1.000	451	1.000

The 451 new syphilitic cases of the year were divided into 164 primaries and very early cases, 136 secondary cases, 107 late syphilitics and 44 congenitals. From the preceding

table it will be seen that 126 of the 451 patients, or 28%, came only once to the clinic. Seventy per cent. of the patients made less than five visits,—a number insufficient in most cases to relieve even the presenting symptoms for which they entered,—and 9% only came more than eight times. The two half-years represent two different medical services, and it will be noticed that the differences in the patients paying one, two, three, four, and five visits are negligible. The more recent service naturally has fewer patients paying a large number of visits.

The attendance of the 451 patients has been analyzed from another stand-point to show the difference between the visits required for relatively good treatment and the number that they actually made. An average of one visit every three weeks from the time of entrance to September 1st has been arbitrarily selected as a minimum measure of efficient treatment. Thus 31 patients coming to the clinic during May theoretically ought to have made an average of six visits apiece during the four months to September 1st, or 186 visits for that group. The table in detail is as follows:

Month	No. of Patients.	Required Visits.	Actual Visits.	Percentage.
July	45	945	234	.247
August	55	1100	220	.200
September	32	576	160	.278
October	42	714	176	.246
November	36	540	153	.283
December	40	560	141	.252
Total	250	4435	1084	.244
January	33	396	107	.308
February	28	308	87	.282
March	36	324	127	.392
April	31	248	130	.524
May	31	186	115	.618
June	42	210	145	.690
Total	201	1672	711	.425
Grand total 451		6107	1795	.294

During the months from July, 1913, to December, 1913, inclusive, 250 new cases of syphilis visited the clinic. On the bases referred to 4435 visits ought to have been made by these patients. Actually 1084 were made or 24.4% of the required number. This percentage remained fairly constant throughout the period, the variations among the six months being only between 20% and 28%.

During the six months beginning January, 1914, and closing June 30 there were 201 new cases of syphilis who up to the close of September should have paid on the basis assumed 1672 visits. Actually 711 visits were paid or 42½%. The percentages show interesting increases during the more recent months as follows: January, 30.8%; February, 28.2%; March, 39.2%; April, 52.4%; May, 61.8%; June, 69.0%.

Summarizing the two half years it was found that during the twelve months beginning July

1st, 1913, the 451 cases should have paid 6107 visits to the clinic up to the close of August. Actually 1795 visits were paid or 29.4% of the needed number.

The explanation of the increasingly better attendance during the recent months is a simple one. During the first three months after beginning treatment a considerable portion of the patients come regularly, one-half or more paying the number of visits needed during this period. After the first three months, when symptoms may be relieved but cure cannot have been effected, patients return much less regularly. After the first few months the clinic averages only 25% of the visits required for minimum efficient treatment.

SUMMARY.

1. The amount of syphilis in Massachusetts today is absolutely unknown. Figures from communities where the disease is reportable show it to be one of the two most prevalent infectious diseases with which we are fighting.

2. Every syphilitic case definitely exposes many innocent, clean living people to the disease. Sixty cases of fresh syphilis exposed 134 by coitus, 442 by family or boarding-house life, and 651 by occupational association,—1227 people in all.

3. At present no organized effort is being made to round up the source of every case. Out of the sixty sources of this series only two were brought under medical care. These sixty cases infected at least five others, but no effort was made to trace out infections in over five hundred equally good possibilities.

4. Left to themselves, patients make little effort to follow up even the most elementary treatment.

5. Twenty-eight per cent. of the patients entering the clinic with active symptoms of syphilis never return for treatment.

6. Seventy per cent. made less than five visits,—a number insufficient in most cases to relieve the presenting symptoms for which they entered.

7. After the first few months the syphilitic patients as a whole average only 25% of the visits required for minimum efficient treatment.

AN UNDESCRIBED ULNAR NERVE TROUBLE, DUE TO TENSION FROM SCAR, AND ITS CURE.

By F. J. COTTON, A.M., M.D., F.A.C.S., BOSTON.

FROM observations of the last three years, I have come to regard as a separate class (apparently unrecognized hitherto) lesions of the ulnar nerve at the elbow, due to the intermittent tension produced by elbow motion on a nerve

held rigidly fixed by deep scar. Compression lesions of nerves, associated with fractures, we all recognize,* but this is a different story. Not all these cases have had any fracture at all, and none of them any compression of the nerve, even by scar, so far as could be determined.

The mechanism is purely *fixation of the nerve* by scar tissue, at the turn of the elbow, where it lies in the epitrochlear groove, or in the inch next below this point. Given a nerve so fixed, it must necessarily happen that flexion of the elbow must pull upon it, and ordinary use of the arm must give *intermittent traction* on the nerve trunk. The result may be (see cases to follow) in some measure a paresis in the muscles supplied by the nerve, sometimes with marked atrophy in the muscles of the hand, but more particularly, the damage expresses itself in pain; pain radiating from the elbow down to the last two fingers, with numbness to touch in this region; a numbness not usually serious in itself, but important as an indication of real trouble.

Pain and a partial paresis of the intrinsic muscles of the hand, expressed in weakness and clumsiness in executing the finer movements of the fingers, are the factors which principally form the list of complaints from the patient. Relief of this condition is surgical. Just as in the cases of intermittent nerve-pressure symptoms from recurrent luxation of the nerve at the elbow,¹—so here also, the only remedy is removal of the nerve to a more favorable site; we can relieve symptoms by dissecting out the nerve, carrying it forward and imbedding it in loose fat and muscle.

The case histories tell the story fairly well, though the records leave something to be desired.

CASE 1. W. H.; seen Oct. 30, 1912 for Dr. J. B. Murphy of Taunton, Mass. He had an olecranon fracture which is said to have united in the extended position with stiffening of the elbow. The elbow is then said to have been broken up under an anesthetic, and put up at a right angle. When I saw him first, the elbow was rigid at 135 degrees, and very sensitive. There was much muscle atrophy, both above and below the elbow, and considerable stiffness of wrist and finger motion. There had been no recent improvement. I therefore proceeded, Nov. 4, 1912, to mobilize the joint under anesthesia. After this he had the usual treatment by exercises and massage, and did more than usually well, so far as regaining of elbow motion went. By the following spring, he had, by persistent effort aided by massage, regained motion in flexion to about ten degrees beyond a right angle, and something near fifty degrees of extension, with free rotation and free wrist motion, and with only a little stiffness of the fingers. When I next saw him, a little less than a year after his first visit, the condition had changed notably. Motion and strength were improving slowly, but he again had severe pain, no longer general about the

* Such lesions for instance are described in connection with epitrochlear fracture and displacement of the fragment into the joint, giving nerve compression by tension on the intact periosteal attachments. Cotton, "Dislocation and Joint Fractures." Saunders, 1910, p. 218.

¹ Cotton: BOSTON MED. AND SURG. JOUR., Vol. cxliii, p. 111.

joint, but localized to the inner side and radiating down to the last two fingers, increased by use of the arm, intermittent and pretty severe. There was thickening all about the elbow, as there always had been. On examination, there was thickening in the epitrochlear groove; well marked, though reference to the x-rays, previously taken, showed no epitrochlear damage. Closer study of the elbow showed the nerve easily palpable just above the groove, apparently slightly thickened and abnormally sensitive. There was hyperesthesia of the skin area supplied by the ulnar; there was decided loss of power in the hand muscles supplied by the ulnar; movements of the fingers were clumsy; there was some wasting of the intrinsic muscles of the hand. It required little ingenuity to reconstruct the story. The ulnar nerve, imbedded in the scar tissue that was all about the joint, was constantly pulled on in the persistent exercises used to limber the joint. The scar tissue had not compressed it at all, but had *fixed* it. Protected while the arm was stiff, the bound-down nerve was injured by the *return of joint motion*. I advised operation, but the patient postponed it, in view of pending litigation, and later, depressed over the loss of his suit, declined intervention. He had, however, carried out the lighter régime I had prescribed pending operation, and when I last saw him in March, 1914, the condition was improved as to all nerve symptoms, though by no means normal.

CASE 2. A young boy, seen in consultation. Elbow injury of some months' duration; no fracture. Pain on use of the arm, felt at the elbow, running down to the fourth and fifth fingers; partial loss of power; some atrophy; some filling-up of the epitrochlear groove. Diagnosis made of condition similar to that in Case 1. When operated upon, no nerve compression was found. The nerve was, however, surrounded and held by scar tissue. The surgeon operating considered the exploration negative and did nothing more. Result unknown to me.

CASE 3. I. B.; seen July 31, 1913. Girl of 13; referred to me by Dr. J. H. Sweet, Jr., of Taunton. History of a blow on the right elbow two or three years ago. Lameness of the elbow for a time; then it grew better, but not long after this it grew bad again and from time to time has given much pain and trouble. She has struck the elbow two or three times since then. The elbow shows no sign of previous fracture or luxation. There is, however, distinct thickening in the epitrochlear groove, and the nerve just above this point is sensitive. Pressure on the nerve gives tingling pain down the arm, and sharp flexion of the elbow gives like pain. There is decided clumsiness in motions of the hand, and moderate atrophy of the intrinsic muscles of the hand; there is definite and considerable hyperesthesia over the ulnar area; there is an abnormal smooth look to the hand, and a definite beginning of the "*main en griffe*" attitude. There have been ulcerations about the nails of the last two fingers, obviously "trophic." Operation advised and carried out Aug. 9, 1913. Incision on the inner side of the elbow down onto the ulnar nerve showed it a bit thick above the joint. At a level just above the epicondyle, it disappeared downward into a mass of fairly dense fibrous tissue, to which it was everywhere adherent, though nowhere compressed. The nerve had to be dissected out for over an inch of its length. Below this point, it was free and normal.

The nerve was lifted from its bed, carried well forward of the condyle, and laid in a groove of fat and superficial fascia, which was lightly stitched about it. The wound was then sewed and the arm put up at right angles. The next day sensation had become approximately normal, and the fingers were better handled and felt more normal to her. Improvement within three days was startlingly rapid. She went home then, but reported in nine days with an arm and hand normal, except for incomplete repair of muscle atrophy. At forty days she wrote of the arm as normal, except for some tremor of the hand after writing. Three weeks later she fell down stairs, and had some return of pain at the elbow but no motor disturbance. Since then I had no news of her until Dec. 23, 1914, when she wrote in response to my letter of inquiry to the effect that the hand was normal, save for some "hurt" after "using it hard or long." She is in school, writing with this hand. She writes that there have been two "sores," since I saw her, so evidently the operation, while very serviceable, was not an absolute cure.

CASE 4. E. McC., aged 12 years. Came to me, referred by Dr. Charles H. Hare, Jan. 28, 1914. She had broken her right elbow early in September, 1913, in a distant town. The fracture was reduced; put up in splints, then in plaster, to Oct. 12, 1913; later subjected to passive motion of the usual sort, once under an anesthetic. The patient was a tall, slight, but vigorous girl, who showed nothing of interest save the right arm, which was carried, helpless, at her side. The hand was shiny-skinned and smooth; the fingers were held in the *main-en-griffe* attitude. The muscles of the hand innervated by the ulnar nerve were all wasted, and their action weak and uncertain. There was very definite though incomplete sensory loss in the region of the ulnar supply. There was much radiating pain in the ulnar supply, increased by attempted use of the hand. Besides this, however, there was distinct loss of power and a trace of dulling of sensation in all the muscles and the skin surface belonging to median and radial nerves below the elbow. Obviously we were dealing in part with the results of a compression-lesion, due to fracture or reduction, or more likely, to splint-compression. There was, however, distinct thickening about the ulnar nerve in the groove under the epitrochlea. Evidently the fracture had been supracondylar; position and motion at the elbow were excellent. I sent her to Dr. J. W. Courtney for a neurological opinion, and he found the ulnar nerve most affected, and advised operation on the chance.

Jan. 30, 1914, I operated. Again the nerve lay in a mass of scar; again it was dissected out, swung forward, and imbedded in a roll of fat, and stitched in place. Within three days, improvement was marked. The hand was warmer; the fingers more responsive; the pains less. Improvement was steady, and as the ulnar nerve supply returned to normal, so also did the muscles of the median and musculospiral groups, though these nerves were not touched. June 16, 1914, she was discharged apparently well in every way, as to freedom from pain, and as to muscle function and sensation.

CASE 5. J. W. B.; referred to me by Dr. G. P. Laton of Salem, N. H. Seen July 14, 1914; age, 55; height, 5 feet, 10½ inches; weight, 195 pounds; occupation, carpenter. History of injury was, that in car derailment April 12, 1914, he was thrown fifteen

feet or so, landing on the right side, shoulder, and elbow. He shows a typical picture of subdeltoid bursal adhesions, but also the picture of ulnar nerve involvement; a little dulling of sensation in the last two fingers; muscle action within the ulnar supply very defective; considerable atrophy of muscle in the thenar and hypothenar eminences and in the substance of the palm. There was definite thickening below the epitrochlea; a thickening into which the large but not abnormally thickened or sensitive ulnar nerve disappears. He was treated with baking and massage for three months, without improvement. The notes of the operation are as follows:

Operation Oct. 22, 1914, Scobey Hospital. Incision in right arm, over epitrochlea, and about four inches above and below; ulnar nerve dissected out of its bed. From about half an inch above the epitrochlea, it is normal in appearance and in surroundings; below this point, the nerve is surrounded by a good deal of rather dense scar tissue, making a very definite sheath, out of which the nerve could be lifted only after dissection of adhesions. As usual there was no compression of the nerve at any point, the nerve trunk appearing rather thicker and perhaps a trifle pinker than normal. Nerve carried, after this dissection, clear of the epicondyle in front, and stitched down in a bed of fat, fascia and muscle, coming back to its normal course in a mass of fat above, in the mass of pronator muscle below. Right shoulder manipulated with the breaking of two distinct adhesions, one of which gave way in abduction, and the other in internal rotation. Arm then showed full normal motion; put up in plaster in abduction and in more than the usual outward rotation. Much pain on recovery, in shoulder only.

Dec. 15, 1914. Hand looks entirely normal; use normal. The only thing left in regard to the ulnar nerve is a slight sensitiveness where the nerve crosses the elbow, in its new position, when he tries to use a screw driver hard, and a trace left of the atrophy of the ulnar side of the forearm; a hardly perceptible trace. Muscles of the hand have already regained almost their normal bulk. The shoulder shows slight improvement; less painful, and range of motion is increased a little. I do not think the present condition warrants the advisability of further interference. He is to go ahead with exercises, as usual, but not very strenuously, and is to report about the first of the year.

Jan. 5, 1915. Hand entirely normal, except for a trace of the atrophy of the muscle in the hand; use of it entirely normal. Shoulder progressing in usefulness, but a bit slowly.

CASE 6. F. E. A., seen Oct. 2, 1914, for the Industrial Accident Board. He is a painter and decorator; age 57 years. Medical history of no interest up to an accident sustained Aug. 30, 1913, when he fell with a staging about ten feet, striking his left arm as he fell. He was under hospital treatment for ten days. For over a year, no treatment save massage and liniments, and with no substantial improvement. He complains of loss of power in the hand and of numbness. The left elbow showed slight limitation of extension; marked thickening about the inner side of the elbow. Atrophy of muscles in the ulnar supply not extreme, but they show partial loss of power and there is a very definite clumsiness in executing the finer motions of the hand. There is definite partial anesthesia of the third and fourth fingers. In this case, the thicken-

ing at the elbow was so marked that a diagnosis of epitrochlear fracture could be made definitely.

He was later sent to me by Mr. H. Edsall of the General Accident Co., with a view to repairing damage, and on Oct. 24, 1914, I operated at the Scobey Hospital. Incision showed the ulnar nerve embedded below the elbow in a tough fibrous mass, so hard that it "whistled" when cut. This extended for a little distance above and for about three-fourths of an inch below the epitrochlea. The nerve was solidly adherent all through this region, but when dissected out, was not itself in any way abnormal. The nerve in this region and for three inches above the elbow, though normal, was a large ulnar nerve. Dissection carried down into the flexor muscle mass. After the nerve had been cut out of the groove at the back of the condyle, investigation showed the fragment felt at examination to lie directly below the epicondyle, and between it and the place where the nerve lay was only fibrous tissue; a piece of the bone, one-half to five-eighths of an inch, was removed without opening the joint. The nerve was transplanted forward into a very satisfactory bed of fat, covering it on both sides. Arm put up at right angles in sling.

Nov. 4, 1914. Still shows a trace of the muscle atrophy previously present, but muscle power everywhere is good; can spread his fingers perfectly well, etc. The partial anesthesia of which he complained has entirely disappeared; feeling the same in these two fingers as in the others; as he expresses it "life has come back into the hand." Now shows nothing excepting the scar, and the slight thickening in the bend of the elbow, where the fact was rolled up to make a bed for the nerve.

When last seen, Nov. 23, 1914, he showed a hand in all respects normal save for a trace of the muscle atrophy. Sensation was perfect and the coördination of the finer movements of the hand entirely restored.

CASE 7. J. S., teamster, aged 46 years; seen Nov. 20, 1914, for Mr. H. Edsall. He says that on the day after Thanksgiving, 1913, he was sitting on his team, when the horses started suddenly. He lost his balance and fell on his right elbow. Went to the City Hospital, and was treated with the arm in a sling in a flexed position for three months, according to him. An x-ray was taken. Later, was treated at Tewksbury, and here also an x-ray was taken. He proved to be a vigorous sort of a man, looking less than his age. The right elbow showed limitation of about 25 degrees in extension; a little less in flexion and rotation. The limitation was purely a loss of mobility, not painful. (Later examination of the early x-rays at the Boston City Hospital showed nothing but a moderate articular thickening of the sort one finds in laboring men of middle age.) More interesting was the loss of power in the muscles of the hand, and the trace of anesthesia in the region supplied by the ulnar nerve. There was also some stiffening of the fingers, due in my opinion, partly, like the elbow stiffness, to overlong fixation; partly to defective power in the muscles that should have been limbering up the fingers during the past year. The hand muscles were a good deal wasted. The condition had been stationary for some months at least. Below and behind the elbow, in this case as in the others, was a very definite thickening into which the nerve disappeared downward. I advised operation and operated Dec. 16, 1914. Incision just behind epicondyle, five inches long. Ulnar nerve found firmly bound to a point above the epicondyle;

very firmly adherent in dense scar mass which was in this instance not very thick but rigid and tough. Same operation done as in the other cases, imbedding the nerve in fat, in this instance for the entire length of its new course. Nerve in this case could not be carried quite as far forward as the others, but well clear of the condyle. The motion of the elbow was no freer under ether, and attempts at stretching it met with definite fibrous resistance, not to be overcome. Usual dressing.

In this case also there was within three days a subjective improvement and within a week the anesthesia was all gone and the fingers could be handled better.

Jan. 5, 1915, examination showed definite improvement in regard to the atrophy of muscles; firmer grasp; good, practically perfect, coördination in the finer movements of the hand; and most encouraging of all, real improvement in the range of flexion of the fingers. The condition at the elbow, as regards motion, does not show any change.

Jan. 19, 1915. No pain; very definite improvement in motion of fingers and in wrist motion. Fingers handled much better.

Despite minor differences, these cases clearly belong in a class by themselves,—a class not apparently recognized in the previous literature. The conditions found at operation, together with the surprisingly abrupt relief of anesthesia (and of pain, in case it had been present previously) and the very rapid improvement in motor function, with prompt rebuilding of atrophic muscle, all lead me to class these as lesions due to the constant irritation of the fixed nerve by flexion and extension movements, rather than as compression lesions.

Perhaps my having seen so many of these curious cases in a short period may be only a chance, but I cannot help suspecting that this lesion may often have been unnoticed as well as undescribed. The resultant disability is not inconsiderable, and it behooves us to keep an eye open for these cases—if for no other reason, because they are so easily cured, and so quickly.

SOME NERVOUS AFFECTIONS IN WHICH MASSAGE DESERVES MORE FREQUENT USE.*

BY J. W. COURTNEY, M.D., BOSTON.

THAT massage is an important therapeutic factor has long since been an established fact. Whether or not it holds a position as prominent as it deserves in the therapy of nervous disorders is debatable. The question is one which I shall, in this brief communication, not attempt to settle. I shall content myself with pointing out to you certain nervous disorders in which massage in some form might with benefit be more frequently employed.

In the rather large group of myospasms there

* Paper read before the Massachusetts Therapeutic Massage Association, January 12, 1915.

are two varieties peculiarly rebellious to drug treatment. One of these you probably know under the name of wry-neck, the other as writer's cramp—a disorder by no means confined to penmen, but found also among typists and among artisans whose occupations demand an incessant abuse of the coördinated movement of the smaller muscles of fingers and hands.

In the wry-neck variety of myospasm I am thoroughly satisfied that, in most cases, the seat of the trouble is to be found in the cortex of the brain. I hold this belief for two reasons: first, because of the absolute inefficacy of local surgery as a curative measure; and second, because of the relief sometimes obtained in the spasmodic cases through the effect produced upon the mind by a supposed operation. In two cases of very long standing which came under my observation a few years ago, Dr. Bottomley, at my suggestion, excised fairly large pieces of the nerves supplying the muscles involved in the spasm. The operation was painstaking and thorough in both cases. In neither case was any permanent benefit derived.

Sedative and anti-spasmodic drugs are likewise of little value in these cases, so that both surgery and drugs offer but slight hope of relief to the unfortunate sufferer whose plight is almost inexpressible. Massage, systematic and persistent, resistive motion and muscle stretching, on the other hand, are of genuine and lasting value in the condition in question. Their effects are not immediate—indeed, it is not to be expected that they should be; but the ultimate relief from them is far more tangible and permanent than that obtained in any other way. Another distinct advantage possessed by the manipulative method in these cases is to be found on the psychic side. The patient feels that something definite and tangible is being done for him, and his courage to make the fight for recovery is sustained thereby. Those of you who have had occasion to treat cases of spasmodic wry-neck will at once recognize the importance of this aspect of the treatment. Without the encouragement thus derived, the patient is very apt to develop a melancholy which leads to the taking of dangerous drugs or to actual suicide.

In writer's cramp and other vocational myospasms, the curative value of massage and gymnastic exercise is overlooked with regrettable frequency by members of the medical profession. In such cases we are dealing, as I have already said, with an abuse of function of certain finely coördinated groups of muscles, with the result that when the endeavor is made to bring the abused muscles into function, the overwrought nerves which control the desired coördinated muscular activity lose their controlling power; and the end result is spasm of the muscles called upon, pain and other evidence of disordered sensibility.

No cure is to be expected in such cases so long as the occupation which brings about the

spasm and accompanying discomfort is persisted in. But treatment by local rest and tonics seldom, in itself, suffices to bring about a cure. What is needed above all things is massage, usually in the form of deep manipulation. This, however, should be applied to the muscles which are the antagonists of those in spasm rather than to the spasmodic group itself. The rationale of this treatment is to be found in the increase in vigor and resisting power which, by the treatment, is imparted to the resisting muscles.

The next class of cases in which I have finally come to the belief that massage will prove its efficiency, if it is given a fair trial, is that of so-called cerebral *contusion*. Cerebral contusion of the modern medical nomenclature is identical with what, in former times, was commonly called "concussion of the brain." The old notion was that when a blow of moderate severity was inflicted upon the skull, its contents were shaken up like so many dried peas in a pod, and that the symptoms produced were due to a temporary disarrangement of the nervous elements of which the brain is composed. Modern pathologic research has shown conclusively that this notion is entirely erroneous. As a matter of fact, when a wounding force of moderate severity is applied to the skull, its immediate effects are primarily made manifest in the brain bloodvessels. These vessels are supplied with sympathetic nerves which afford them an independent power of contraction and dilatation. Under the shock of an applied force the sympathetic or vasomotor nerves in question are immediately put out of function, and circulation within the brain ceases to a greater or lesser extent. With this cessation in vascular function two things immediately happen—first, a clotting of the blood in certain capillaries; and second, a leakage through the vessel walls of the watery contents of the blood. If only a small area of the brain is involved in this morbid process, the circulation finally rights itself and the watery effusion is absorbed. If, on the other hand, the brain area involved is extensive and the amount of fluid poured out into the brain substance great, the burden of absorption and removal of this fluid thrown upon the great venous pathways from the brain is so overwhelming that these conduits fail in their function, the brain becomes waterlogged and death ensues.

Up to the present time the measures adopted by the surgeon in the above-mentioned situation have been inadequate to cope with the effused death-dealing fluid with entire success, and, as I have already said, I cannot help feeling that in massage we have an important adjunct to the surgeon's endeavors. A stroking or *effleurage* of the neck tends, as you very well know, to a rapid depletion of the jugular veins and creates a sort of suction. This suction would, in my opinion, strongly favor the evacuation of effused fluid from the brain itself and to a remarkable degree the drainage established by the trephining operation of the surgeon. It is my hope

that in the future the masseur may have increasing opportunities to prove the worth of his manipulations in this class of cases.

Owing to the fact that most organic diseases of the brain and spinal cord are incurable, the physicians in charge of cases representing these diseases are too frequently wont to limit their therapeutic endeavors to the administration of either iodide of potash or of that other standby of neurologic therapy—strychnine. More often than not, under these circumstances, the iodide is useless and the strychnine positively harmful in that, by its stimulating action, it serves to increase the painful muscular contractures accompanying the disease under treatment.

In the majority of cases where the lateral columns of the spinal cord are involved, massage and passive motion are the only therapeutic agents really indicated. It matters little whether the primary focus of disease is in the brain or in the cord itself; the resultant damage is weakness and stiffness—sometimes amounting to actual contracture—of the affected limbs. And to these disabilities a local sluggishness of circulation is not infrequently added by reason of a concomitant disturbance of what we may term the check-rein nerves of the skin blood vessels—the vasomotors.

The value of massage in such conditions is twofold: It acts centripetally, stimulating the tissues about the central focus of the disease and peripherally, it improves circulation, retards muscular wasting with its consequent weakness, and prevents severe deformities.

There are many who scoff at any measure designed to combat the ravages of organic disease of unknown or doubtful origin in the central nervous system, but after fairly long experience with this form of disease I can frankly say that I do not share their pessimism. I have just spoken of the value of massage in lateral column disorders and will now speak in turn of what may be expected from it in affections of those remaining portions of the cord which are of the greatest and best known functional importance,—the anterior gray horns and the posterior columns.

In that disease of the anterior horns, known as progressive muscular atrophy, I cannot truthfully say that I have found massage of any particular value, but in what we may term the late regressive stages of infantile paralysis—a disease of this same region—there is no question of its efficacy. In fact, I consider it of as great importance in the maintenance of muscular nutrition and the correction of paralytic deformities as any other measure that has ever been adopted. To obtain the best results from it, however, its use must be extended over a long period of time.

Locomotor ataxia represents the most commonly encountered disease of the last-remaining portion of the spinal cord above mentioned, and in it massage—either alone or in combination with reëducation in coördinative movements of affected muscles—serves a useful purpose. Here

again its action is twofold, as in the case of lateral column degeneration, in the sense that its beneficial effects are felt both peripherally and centrally, although it does not have identical conditions to combat.

In Parkinson's disease (*paralysis agitans*) I have found massage very useful in allaying the feeling of tension, stiffness and awkwardness that so often accompanies the shaking. Here, however, only the gentlest kneading and the mildest sort of passive motion should be applied.

I am sorry that I have not had the time to specifically indicate the other forms of organic disease of the central nervous system in which the employment of the therapeutic agent in question is attended with undoubted benefit. I will say, however, that it should be more frequently used in all cases of central disease accompanied by deformities of joints and in the majority of those associated with atrophy. In the latter group I make exception of syringomyelia as well as of the so-called progressive muscular atrophy, in which diseases I have found it of doubtful value only.

It is hardly relevant in this paper to speak of the use of massage in cases of peripheral nerve suture because its employment in such cases is the rule rather than the exception. But I cannot refrain from touching upon this subject in order to emphasize one very practical point, namely, the absolute necessity for patient perseverance. Even where early end-to-end suture of a divided nerve-trunk is made, the process of union is, as a rule, tediously slow and inexpressibly discouraging. Months may elapse before massage appears to make any satisfactory impression upon the muscles that have been rendered wasted and inert by the severance of their nutrient nerve. But persistent massage acting centripetally will ultimately bring about most gratifying results in the way of improved nutrition and motion in the affected muscles. In cases where surgical union of a divided nerve is delayed for some time, the problem of the masseur is distinctly greater and he must bring into his handling of the case a fund of patience that is well-nigh inexhaustible.

With the above digression I come to a final group of morbid nervous phenomena in which the use of massage is by no means unknown, but in which it might, with great profit, be more frequently employed. I refer to phenomena which represent a state of pathologic exhaustion of the nervous centres and which are classified under our present rather unsatisfactory nomenclature as symptom-complexes of the so-called psychoneuroses.

As you perfectly well know, the patient with hysteria or neurasthenia is, with annoying frequency, looked upon by physician and layman alike as the victim of nothing more nor less than his own wilfully morbid imagination. Such a tenet on the part of a layman, ignorant as he is of all knowledge of anatomy, physiology and hygiene, is hardly to be wondered at. When

on the other hand, a physician conducts his treatment of the pitiable sufferer from exhausted nerve centres on the basis of the same tenet, the *raison d'être* of this treatment is akin to that of the exorcism of mediaeval times.

As a plain matter of fact the problem of etiology in exhausted nervous centres is far too deep and subtle to be disposed of in any offhand way. Into this problem I shall not here delve, but shall confine myself to the consideration of those clinical manifestations of the exhaustion in which the use of massage is indicated much more often than it is actually employed.

Nervous exhaustion is characterized by morbid emotional states, by a prompt fatigability of motor neurones, by perverted sensibility of the most varied form and by curious morbid fluctuations in the activities of that delicate mechanism known as the great sympathetic nervous system.

In the severe cases the feeling of fatigue is so marked and so constant that it is with the greatest difficulty that the sufferer is able to use his upper extremities for more than a few minutes at a time or to drag his weary legs for even the shortest distance. The advice often given to such a person by the misguided medical man is to take more exercise, and if this advice is followed, it invariably leads to such an increase in the exhaustion that existence is rendered almost unendurable.

What such a person really needs is the very gentle stimulation of motor neurones and voluntary muscles, which skilfully applied massage so marvelously well supplies. Under such manipulation the unhealthy tension of over-tired motor nerves is relieved, the muscles lose their vice-like feeling of tension, the skin circulation is equalized in the various regions of body and extremities and the emotional tone is altered for the time being from one of irritability, anxiety and depression to one of pleasant languor.

Under the same sort of manipulation the tender and at times extremely painful spine is restored to normal feeling. I have been particularly struck by the analgesic action of carefully graduated massage in this condition; indeed, I have frequently seen spines so exquisitely tender at the outset that the lightest *effleurage* of a gentle operator was intolerable, gradually become, under this treatment, so free from morbid sensitiveness that even the heaviest handling was grateful rather than otherwise.

We come, finally, to a consideration of the disturbances which arise through the faulty working of the great sympathetic system in states of nervous exhaustion. It has always seemed to me curious that Nature has put such a burden of function upon this, the most delicate part of the dynamo that runs the human machine. But such is the fact.

At times it governs, at other times it is governed by, our emotional life. It regulates the amount of blood that at any one time is in a particular part of the brain. It controls respiration, the beat of the heart, digestion, glandular

secretion in general, the secretion and excretion of urine, the peristaltic action of the bowels, the menstrual function and the surface circulation—in a word, it holds the sceptre over a very large territory in the human economy. Hence, when it is brought by exhaustion to a state of irritability it produces the over-activity in brain circulation which underlies insomnia, the cold, mottled and moist extremities, the suffocated feelings, the palpitations, the sluggish and painful digestion, the constipation, the increased or diminished urinary output, and the painful, delayed and scanty menstruation so often encountered in the victims of the so-called psychoneuroses.

Here is a pathologic problem with which no system of therapy that does not give a prominent place to massage can possibly hope to cope successfully. By massage, in the form of *effleurage*, we can deplete the over-filled vessels of the brain and bring about the much-needed mental peace and refreshing sleep. By the same agent we can equalize surface circulation and surface temperature throughout the body and limbs; we can stimulate sluggish peristalsis and relieve the pain caused by the distention of retained flatus; we can prevent the sagging of the stomach and intestines due to atony and, in certain cases, we can—I feel confident—bring about a return to normal of the menstrual function.

There is probably nothing in this very brief communication that was not known to each and every one of you long since; but it was not my purpose to bring to your notice those forms of nervous disorder in whose treatment massage has not as yet proved its practical efficacy; on the contrary, my aim was to stimulate a greater tendency to its employment in cases in which its therapeutic value is practically indisputable. This I have not done as thoroughly as I should like, but as thoroughly as my limited leisure permitted. I ask your indulgence for my shortcomings.

Medical Progress.

EIGHTH REPORT OF PROGRESS IN ORTHOPAEDIC SURGERY.*

By ROBERT B. OSGOOD, M.D.; ROBERT SOUTER, M.D.;
HERMANN BUCHHOLZ, M.D.; HARRY C. LOW, M.D.;
AND MURRAY S. DANFORTH, M.D., BOSTON.

(Concluded from page 452.)

RICKETS. OSTEOMALACIA. CHONDRODYSSTROPHIA
FETALIS. OSTEOGENESIS IMPERFECTA.

Weiss³⁰ reports a series of cases of rickets, some mild and some severe, in which there was a very marked improvement in their condition under the administration of tablets of the extract of the hypophysis. This improvement occurred in from six to ten weeks.

Cavazzani³¹ had observed great benefit follow

the administration of epinephrin in three cases of osteomalacia. The disease occurred in women who had borne one or more children. In the first case it was begun about a week after the first symptoms, which had come on acutely a few days after delivery. The treatment was promptly effectual. In the second case the osteomalacia had developed not long after delivery, but two months had elapsed before treatment was instituted. The treatment was not kept up regularly and the results were less striking. In the third case, although the disease had existed for a long time and there were irreparable lesions, a very marked improvement took place.

Wagner³², in reporting a case of chondrodysplasia fetalis transmitted from mother to child, calls attention to the influence of heredity and the fact that the usual transmission is from father to child. The author, while admitting that there is no conclusive evidence of specific disturbance of function of any of the glands of internal secretion, believes that there is probably a hypersecretion of the reproductive glands which causes an abnormal development of muscles and genitalia. An histological study reveals irregular columns of cartilage cells at the epiphyseal line, the cells being pushed apart, especially at the periphery, as if the periosteum had been driven into the cartilage. Wagner thinks that this abnormality of enchondral bone formation is associated with increased tension in the direction of the long axis of the bone by the hypertrophied muscles, resulting in the micro-nelia.

Bookman³³ has accepted an opportunity to study the metabolism in a case of osteogenesis imperfecta for a considerable period of time, especially with reference to the calcium retention and output. His three conclusions are as follows: 1. Calcium retention may be much below normal. 2. During the course of the disease it varies widely. 3. Cod-liver oil and phosphorus, and more especially calcium lactate increase the calcium retention. Bookman compares his observations with the earlier work of Bamberg and Huldehinsky³⁴, who after a study of their own cases and a review of the literature, conclude that osteogenesis imperfecta (Vrolik) and osteopsathyrosis idiopathica (Lobstein) present very similar clinical pictures. They believe that fifty per cent. of the cases of osteopsathyrosis, which condition comes on at varying periods after birth, are hereditary. In the earlier congenital osteogenesis imperfecta they find that heredity plays no part. A histological study shows, in contradistinction to the picture of chondrodysplasia fetalis, aplasia of the compact tissue and spongy substance of the diaphysis and epiphysis with normal growth of cartilage, resulting in the development of slender bones, with little spongy substance and weak compact tissue. They consider that disturbance of function and defective formation of the periosteum is the direct cause of these changes. Both early and late

forms show the same changes. In regard to the calcium metabolism, their work seems to show that the disease is not caused by a loss of calcium, but by the incomplete rudimentary formation of the bones with irregular distribution of calcium. They agree with Bookman that the retention of calcium can be increased by phosphorized cod liver oil. The prognosis in the forms occurring before birth is bad. Of 31 cases collected, only three survived. In the late forms it is good, in 105 cases there being no death from the disease.

SCOLIOSIS.

In a series of 22 cases of scoliosis, not selected, but taking all in which good x-rays were obtained, in the Orthopaedic Clinic of the Massachusetts General Hospital, Adams³⁵ has studied the abnormalities in the vertebral column. Two cases showed abnormalities of the dorsal vertebrae, and nineteen, abnormalities of the low lumbar or sacral segments. The only remaining case was one of scoliosis, following poliomyelitis, in which there was no bony abnormality.

[Ed. Note.—Such findings in x-rays made as a routine in a scoliosis clinic, show the need of careful study of the lumbo-sacral region in all cases of lateral curvature, for upon the cause must depend to some extent the details of treatment, and also upon the cause must depend the prognosis as to our ability to maintain a correction once obtained. If we can become convinced that these abnormalities represent the cause of the deformity, we are at once faced by the question as to whether in many cases at least we should not attempt to correct the static influence of the deformity by operation, either before or after the correction of the scoliosis. This may furnish a further field for bone grafting and spinal surgery in general. The suggestiveness of this paper of Adams is enhanced by the reports which come in from various sources, in which the authors from their observations feel still uncertain as to the permanence of the results obtained by the forcible methods of Abbott and others.]

JOINT SURGERY.

Murphy³⁶ has written a valuable paper on the technic of arthroplastic operations for bony and fibrous ankylosis of the temporomandibular articulation. He believes the cause to be either an infection or a trauma transmitted from the chin. The differential diagnosis as to which side of the jaw is affected may be extremely difficult. In the intra-articular ankyloses there is sometimes a little motion on the unaffected side. An important point is that the face on the affected side is full and round and apparently normal in appearance, while on the opposite or unaffected side it is flattened and deformed. The chin is always more or less retracted and deviates toward the ankylosed side. The muscles on the affected side are always more atrophied. The most important points in his technic are an

L-shaped incision in front of the ear and along the zygoma. No attempt is made to remove the head of the bone from the glenoid cavity on account of the danger of penetrating the skull. The pedicle flap of fat and fascia is lifted from the surface of the temporal muscle and turned downward. A wooden wedge is inserted between the jaws on the affected side. Mastication is begun in two weeks. He reports nine cases with good results in eight.

W. L. and C. P. Brown³⁷ describe an operation for arthroplasty of the shoulder joint, and while they have had only one case, the result was excellent and the procedure is surely ingenious. The joint is exposed by an anterior incision. The pectoralis major tendon is divided at the humerus and the inner fibres of the deltoid are also divided. The short head of the biceps is cut across about $4\frac{1}{2}$ inches below the glenoid and the muscle with pedicle attached is turned into the glenoid and fastened by sutures. The pectoralis major is sutured if possible and the arm put up in abduction.

Payr's³⁸ experience in arthroplastic operations has been large and his constant attempts to improve his technic and study his results make the report of his further experience of great value. His first cases are now about four years old. He is still impressed with the importance of the removal of the synovia and fibrous cartilage, and if possible of the whole capsule as well. His experiments seem to show that the final tissue covering the bone ends resembles that of tendon sheaths. He has never seen new cartilage formation, and the bursa-like nearthrosis is a unique structure. He finds that the ends of the bones adapt themselves to the mechanism of movement, the spongiosa becoming more dense and a sort of cortical bone forming. As to the indications, Payr considers that it is essential that the operation should be deferred until long after all signs of active inflammation have subsided. He believes this cannot be emphasized too much. Some of his knees have been done in two stages, the first, the mobilization of the patella, and later, after exercise of the quadriceps, the main joint has been reshaped. He approaches the joint by two lateral incisions, having abandoned Kirschner's method of trapezoidal resection of the tibial tubercle, because it was noticed that the healing of the bone was not good. He has evidently had difficulty, as have the Editors, with the occurrence of bony spurs on the posterior edge of the tibia and femur. He believes this may be avoided by removing the periosteum from this region as exactly as possible. He begins massage of the muscles early and gentle movements of the joint in two or three weeks. He employs traction sufficient to separate the bones as much as he considers necessary. In the knee he considers 90 to 100° of motion all that is desirable. In bony ankylosis of the hip he considers a pseudarthrosis of the upper end of the femur may be the best procedure. He reports 11 cases of knee

joints, as 2 bad, 2 good, 7 very good; 3 cases of hip joints as 1 bad, 2 very good; 3 cases of elbow joints, as 1 good, 2 very good; 2 cases of finger joints as successful; 1 case of shoulder joint as unsuccessful.

BONE SURGERY.

Lewis³⁹ summarizes the results of his experimental work in bone transplantation as follows: The cortex, without periosteum, endosteum, or marrow, will remain alive and proliferate when small bits are imbedded in muscle tissue. Direct contact with living bone is unnecessary. Large pieces of bone transplanted onto live bone, remain alive. Bony growth may fill in without the aid of a periosteal or bony bridge, and strips of fascia may take the place of the periosteum as a limiting and nutritional membrane. In one case three inches of the excised shaft where the periosteum had been scraped away, was regenerated in this way. At autopsy nine weeks later, moderately firm bony callus was present, and the fascia had fused with the periosteum further up the shaft with an almost indefinable dividing line.

Bond⁴⁰, in reporting two cases of successful transplantation of the fibula to replace the tibia in which there had been satisfactory increase in size as far as thickening was concerned, but not sufficient growth in length, discusses the controlling factors in this growth. There seems to be little reason to doubt that imperfect epiphyseal function is the cause of defective growth in length. He believes after consideration of various theories that the increase in thickness is simply in response to the necessity of function, and that we may expect these changes in transplants in other parts of the body, although we are unable to describe the process of cell reproduction which brings this about.

Marcuzzi⁴¹ recommends a mixture of equal parts of the phosphate and carbonate of lime as a filling in bone cavities. It is easily sterilized, readily but not quickly absorbed, has a marked affinity for bone, and stimulates osteogenesis. He reports good results.

FRACTURES AND DISLOCATIONS.

Marsiglia⁴² reports experiments undertaken on dogs to determine the effects of injections of emulsions of the hypophysis of calves after fracture. It was found in the dogs studied that the consolidation of the fractures was very much delayed and that the dogs suffered markedly from toxemia, loss in weight, strength, etc.

Tanton⁴³ believes that the gravity of fractures of the coracoid process depends less on the break than on the force necessary to cause the lesion. Malgaigne had six deaths in six cases. With dislocation of the coracoid process inward there is likely to be contusion of the bundles of the axillary nerves, causing complete paralysis of the upper arm, forearm, and hand. This occur-

rence is due to the violence rather than to the fracture. Secondary nervous complications often arise from exuberant overgrowth at the point of fracture. In five out of six cases reported by Dr. Guelt only fibrous union occurred. With displacement of a coracoid process there may be a functional impotence evidenced by a lack of power in the forward motions of the arm. Treatment should consist in immobilization for twelve to fourteen days in forced adduction with a flexed forearm and the elbow elevated. Where there are persistent symptoms from exuberant overgrowth this should be removed.

Saar⁴⁴ has treated six cases of old fractures of the lower end of the humerus which had healed with great backward displacement and complete or nearly complete loss of function of the elbow. In all these cases he mobilized the lower fragment by carefully dissecting away all scar tissue. In some of the cases the lower fragment lay entirely free. He then corrected the position and retained the bone by mortising it to the shaft. In no cases did necrosis occur, and the results in all his cases were good, in two of them normal motion being obtained.

Anzilotti⁴⁵, from a careful study of two cases of forward dislocation of the head of the radius, one recent and one of a year's duration, concludes that in a recent case one should attempt reduction without open operation, but in case of failure to reduce or to maintain the reduction one should make an incision down to the head and replace it, after removing any obstacle. In old dislocations it is necessary to open the joint, remove any obstacles, and if possible replace the head. If this is found impossible one should remove just enough of the head to permit reduction.

Walbaum⁴⁶ reports two cases of the rare fracture of the lesser trochanter, of which, according to his statement, only 12 cases have heretofore been published. In both cases the fracture occurred in connection with running fast; one patient feeling the tear as he abruptly stopped. The symptoms are pain and limping in walking, tenderness over the lesser trochanter, free passive motion, but pain in active motion of the hip joint. Ludloff's sign, the inability to lift the leg from lying position, was positive in one case, but negative in the other. The author believes, therefore, that in the latter case only a part of the lesser trochanter was torn off.

Balthazard⁴⁷ adds another to the cases on record in which after a fall, the patient complaining only of vague pains in the lumbar region, an actual fracture of the spine had occurred. He walked home after the fall, but by the sixth month he complained of girdle pains and there was a hump in the dorso lumbar region. He died from an intercurrent disease, and necropsy revealed that the spine had been fractured, the body of one of the vertebrae had been crushed, and the transverse lamellae broken, but the spinous processes were intact.

[Ed. Note.—We believe that fractures of the spine are much more common than we have been accustomed to consider them. They are associated in our minds with severe immediate symptoms, usually of cord pressure and kyphos, whereas frequently the immediate symptoms are very slight and no kyphos is present. The serious nature of the injury is revealed later when pressure symptoms begin. We feel sure that all injuries of the spine should have an x-ray examination and that when a fracture is found, immobilization should be advised for several months]

Albee⁴⁸ advocates in certain fresh fractures inlaying a bone graft and fastening it with bone autoplasmic pegs. With accurately adjusted twin saws a piece of bone is cut out of the long fragment about five inches in length and a small piece, 2½ inches in length and of exactly the same width and exactly opposite the trough in the long fragment, is cut from the short fragment. From this smaller piece, bone pegs are fashioned by a dowelling machine. The longer piece is inserted in the short fragment and extends an equal distance into the long fragment and is retained by the bone pegs driven through drill holes.

Davidson⁴⁹ reports excellent results in six cases of fracture treated by the introduction of autoplasmic bone pegs made from the tibia. These were introduced into the medullary canal in all cases except in fracture of the neck of the femur, in which a canal was made through the trochanter.

[Ed. Note.—It is quite evident to the Editors that a course in carpentry will soon be a necessary part of the education of every well equipped surgeon.]

MISCELLANEOUS.

Brandes⁵⁰ has studied the time of appearance and the character of bone atrophy caused by disease. He chose the os calcis of rabbits as most suited to his experiments and observed the changes in it as a result of resecting a portion of the tendo Achilles. An atrophy involving both the spongy and compact bone occurred in one week. The tibia and the anterior bones of the foot were involved also. When the function was only partially taken away, as by a plaster cast, an atrophy began very early and was directly proportional to the completeness of the lack of use. From these experiments the author concludes, as did Legg as the result of his similar experiments, that the atrophy seen in disease is the result only of the disuse, and not characteristic of any special disease,—for example, tuberculosis.

A type of enteric fever due to the bacillus *Columbensis* was first described by Castellani⁵¹ in 1905. Certain cultural characteristics and sugar differentiate this organism from others in the paratyphoid group. He describes a case

of this type of fever, in which there were sinuses in the arm, persisting for over a year, from which spicules of bone were discharged, and from which cultures of the *B. Columbensis* were isolated. This apparently represented a peritonitis due to one of the organisms of the typhoid group. The infection is always mild, persistent, and runs a subacute course.

Dehon and Hertz⁵² give the details in fourteen cases of angiosclerotic dystasia or intermittent claudication, and call attention to the fact that syphilis was known in half of them. This large percentage suggests the importance of at least tentative treatment for syphilis in all cases of obliterating arteritis of the legs. One of their patients improved remarkably under specific treatment and the Wassermann reaction became negative. Some with known syphilis had a negative reaction. In some with known syphilis, the intermittent claudication was not benefited in the least by the specific treatment. Tobacco and alcohol seemed to be contributing factors in some of the patients, possibly outweighing in importance the syphilis in these cases. They urge that if any signs of tabes or leukoplakia are present there should be a trial of specific treatment in every case of intermittent claudication, even if there is nothing else to suggest syphilis and the Wassermann reaction proves negative at the first test.

Bailey⁵³ reports four cases of spinal cord tumor and calls attention to the fact that in these tumors pain may be absent, or present only slightly and at intervals. Also that the presence or absence of pain is not of value in determining whether the tumor be extra- or intra-medullary. He says, "We shall have to take the same position in regard to spinal cord tumors as we have taken for years in regard to tabes, that is, that pains may be absent in a disease which is usually highly painful, and that the absence of it in any case presenting other sufficient symptoms does not vitiate the diagnosis."

Goldthwait⁵⁴ has written a suggestive article intended to reach the lay public on the effects of habits of posture on health.

[Ed. Note.—It is undoubtedly true that faulty posture maintained in industrial life becomes a fixed habit and that careless lack of attention also allows a poor posture to become an habitual position of a physically weak individual. These conditions may predispose to various chronic diseases. Although it is quite true that many persons live to be three score years and ten, work hard, and "never have a sick day," and yet are round shouldered, with sagging abdomen, and pronated feet, the efficiency of these individuals must be lessened by these factors. Our attention needs to be called to these matters, but let us not stop there. Proper posture should be a study in every school, ranking with other lessons, and its acquirement made essential to promotion. Gymnasia, with instructors trained in the methods of inducing proper posture must be

developed for general use, if we are going to reach more people than those few to whom we can say, "Sit up straight."]

An article by Lovett⁵⁵ on "The Causes and Treatment of Chronic Backache, with a Consideration of the Diagnosis of Sacro-iliac Relaxation" should be generally read, as the expression of opinion of an eminent orthopaedic surgeon who has given much thought to the subject. Leaving out of consideration the backaches due to tuberculosis, organic nervous disease, and spinal fractures, he considers the common causes are: 1. Pelvic conditions. 2. Traumatism. 3. Arthritis. 4. Defective balance. Sacro-iliac strain or relaxation as an entity, he considers very rare, believing that the backache when located in this region may be attributed to strain upon the muscles, attachments and ligaments in this region, causing a condition of hypersensitiveness and tenderness in which the sacroiliac ligaments are in some cases involved. He believes that the measures often employed to support the sacroiliac joints, such as adhesive plaster and belts, are entirely insufficient to really hold the articulation, and are successful only when they give support to strained muscles or help to maintain a proper balance. The most useful methods of treatment he considers to be: 1. Measures to obtain proper balance, such as corsets, etc. 2. Proper shoes and sometimes supports for the back. 3. Later exercises to develop the musculature.

[Ed. Note.—It is not clear from the article what the author considers the cause of the common sciatic and other nerve root pain which so commonly accompanies both the attitudinal, the traumatic, and the arthritic low backaches. These are frequently relieved by protecting the sacroiliac joints and these alone, by such a procedure as the Italian laborer has learned to adopt, when if hard digging is to be done he shifts his belt from his waist to below the level of his anterior superior spines. He does not know that the difference of a few inches in the circular construction makes the difference as to whether the sacro-iliac joints are sprung apart by pressure applied at the level of the crests of the ilia or held together by pressure exerted in the sulcus between the trochanter and the anterior superior spines, but such is the fact and he does know that his back does not ache when he is thus protected. The author is quite right in saying that any actual displacement of the sacrum downwards is unlikely and possible only as a result of very great trauma. None of the anatomists or clinicians who have carefully studied the movements of the sacrum have maintained that this occurred. (Goldthwait: *BOSTON MEDICAL AND SURGICAL JOURNAL*, May 25 and June 1, 1905. Bouvarre et Bûe: *La Presse Medicale*, Aug. 9, 1899. Herman Myer: *Archiv. für Anatomie*, 1878, p. 1. L. Dieulafe: *Bibliographie Anatomique Supplement*, 1904, p. 109.) Nevertheless, the rotation of the sacrum on its horizontal axis through the second sacral ver-

tebra and slight displacements or subluxations beyond of this normal arc of motion, which the author does not mention, are quite common, we believe, and demonstrable both to palpation and also in good stereoscopic x-ray plates. We cannot explain relief of nerve root pain, when the sacroiliac joints are protected by the theory of relief of strain on the ligaments and muscle attachment of the low back, nor can we explain thus the quick relief which is often dramatic, which sometimes follows manipulation of the joints, either with or without an anesthetic. Muscle attachment and ligamentous strain from faulty attitude and balance are surely a very common cause of backache, but there will, in our opinion, be left many cases not explainable on this theory alone, and in these we believe that lesions of the sacroiliac joints and strains in which abnormalities of the articular and transverse processes of the fifth lumbar are present, will be found not infrequently.]

Book Reviews.

A Text-Book of the Diseases of the Nose and Throat. By JONATHAN WRIGHT, M.D., Director of the Department of the Laboratories of the New York Post-Graduate Medical School and Hospital; and HARMON SMITH, M.D., Surgeon of the Throat Department of the Manhattan Eye, Ear, Nose and Throat Hospital; Clinical Professor of Laryngology and Rhinology, Cornell University Medical School. Illustrated with 313 engravings and 14 plates. Philadelphia and New York: Lea and Febiger. 1914.

This is a new text-book of 650 pages. It is stated in the preface that "the exceptional feature in the book is the emphasis laid upon the etiology and pathology of disease" and that "much of this work rests on original investigation in the laboratory and clinic." One of the authors is an investigator and a philosopher, whose opinion in pathological problems has long been sought, and who in addition to his other writing has given us a classical history of laryngology. The other is a well-known clinician and operator. They have worked together so that there are no abrupt lines of demarcation between the academic and the practical portions of the text. The first chapter gives briefly the various methods of examination. The next on the external nose includes the results of the long experience of one of the authors with the injection of paraffin. The description of the minute anatomy, both normal and pathological, of the internal nose and also of the pharynx and larynx, is one of the striking features of the book. Another, which will undoubtedly lead to its wide use for reference, is the description of the various neoplasms, not too technical, but given by the hand of a master. The selection and description of operations on the accessory sinuses and nasal septum is good and clear. In the chapter on neuroses of the nose is included hay fever, which is apparently looked upon as largely due to a yielding on the part of over-sensitive persons to insignificant irritations. It is disappointing that the large amount of study which has recently been given to the theory of anaphylactic reaction from the different proteids should not be taken seriously. The important subject of the borderline between normal and pathological adenoids and tonsils is judiciously discussed and various methods of operating described. A valuable chapter, often omitted from text-books, is one on buccal lesions, with which the specialist is often called upon to deal. As a whole the book is a worthy addition to our list of text-books on the subject, and justifies its promise to embody original points in etiology and pathology.

THE BOSTON Medical and Surgical Journal

An independently owned Journal of Medicine and Surgery, published weekly, under the direction of the Editors and an Advisory Committee, by the BOSTON MEDICAL AND SURGICAL JOURNAL SOCIETY, INC.

THURSDAY, APRIL 1, 1915.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States. \$6.56 per year for all foreign countries belonging to the Postal Union.

The editor will be in the editorial office daily, except Wednesday and Sunday, from twelve to one-thirty p. m.

Papers for publication and all other communications for the Editorial Department should be addressed to the Editor, 126 Massachusetts Ave., Boston. Notices and other material for the editorial pages must be received not later than noon on the Saturday preceding the date of publication. Orders for reprints must be returned in writing to the printer with the galley proof of papers. The Journal will furnish the first one hundred reprints for half the cost price.

All letters containing business communications, or referring to the publication, subscription, or advertising department of the Journal, should be addressed to

ERNEST GREGORY, *Manager.*

126 Massachusetts Ave., Corner Boylston St., Boston, Massachusetts.

NEW AND NON-OFFICIAL REMEDIES, 1915.

THE 1915 edition of *New and Non-official Remedies*, published by the American Medical Association, has recently been issued. This little work,* which is prepared by the Council on Chemistry and Pharmacy of the Medical Association, is not as well known to, or as frequently consulted by, the profession as it should be.

As the name implies, the book deals with drugs which have recently come into use and with those which are not yet contained in the United States Pharmacopoeia. Its main purpose is to give physicians a truthful account of the chemistry, properties, actions and, so far as these have been determined, the therapeutic use of the drugs discussed. As a source of information on such subjects, it should largely replace the trade circulars of manufacturers, from

* Copies of "New and Nonofficial Remedies" may be obtained at cost price, postpaid (50 cents for paper-bound, \$1.00 cloth-bound), from the American Medical Association, 535 North Dearborn Street, Chicago, and also through dealers in medical books.

which so many of the less critical members of the profession derive their knowledge of the more recently introduced remedies.

As examples of the drugs discussed in this edition, may be mentioned salvarsan, emetine, theobromine and theophyllin (and the various proprietary preparations of these, such as diuretin and theocin), novocaine, preparations of the pituitary gland, various vaccines and sera, etc. The list is not limited to substances used for therapeutic purposes; it discusses also the most important chemicals and re-agents recently introduced for use in diagnosis, such as phenolsulphonaphthalein, the Noguichi, Abderhalden and von Pirquet tests.

A very useful feature of the work is the fact that the names of the manufacturers who make such preparations and who have satisfied the Council that their products are as represented, are given. It may not be generally known that the American Medical Association maintains in Chicago an exceptionally well equipped chemical laboratory for the purpose of examining new drugs; this laboratory is probably the best source of trustworthy information in the world on such subjects. The fact that so many physicians still derive so much of their information on these subjects from commercial circulars or retail men, in preference to *New and Non-official Remedies*, is highly discreditable to the profession. An examination of the reports of the chemical laboratory of the American Medical Association, or those of the United States Public Health Service, of the records of convictions under the National Pure Drug and Insecticide laws will show how little reliance can be placed upon the claims of many manufacturers. And yet most physicians constantly prescribe and hospitals constantly buy, at exorbitant prices, simple Pharmacopoeia drugs under proprietary names, simply because the manufacturers say, or insinuate, that their products are superior to the U. S. P. preparations, although the quality of the latter is under the jurisdiction of the United States as well as of the state governments. Why do physicians who accept such statements hesitate to accept other statements of these same manufacturers—those concerning the value of their various pastes for the checking of cancer, of various toxins for pneumonia, etc., as well as the out and out "patent" medicines (hair growers, "manhood restorers," etc.) which the same firms prepare for the use of the laity? It

may well be that the future historian of medicine will find this an essentially darker period in some important respects than that of a century ago, when James Jackson and John C. Warren knew enough about the drugs they used to write a pharmacopoeia for the Massachusetts Medical Society.

All drugs are admitted to *New and Non-official Remedies* provided they meet certain simple requirements—requirements based upon principles universally accepted, but unfortunately not adhered to by the medical profession; they must be non-secret, exact information as to composition must be given, grossly exaggerated claims as to usefulness or safety must not be made. Powerful drugs, the use of which by the laity might lead to harm, either direct or indirect, must not, according to the rules governing admission to the book, be advertised in a way to invite self-medication. With these simple restrictions, the reasonableness of which is self-evident, all new drugs of promise are eligible for admission. Physicians should regard with suspicion all proprietary preparations which are not included.

The reason why the products of some manufacturers are not in *New and Non-official Remedies* is that these firms are not dealing fairly with the profession or the public.

Another feature of the work is that emphasis is laid upon the true chemical names of the drugs. Many physicians will find that they are using proprietary names and so helping create monopolies in certain official drugs, as well as in certain chemical compounds; the use of various proprietary names for the same official drug (as in the case of hexamethylenamine, for example) often leads to the greatest confusion.

HEALTH ASPECTS OF SCHOOL LUNCHES.

THE medical profession is to be credited with initiating the movement to feed children at school. Its beginning, in England, can be traced to a memorandum issued many years ago, by the director-general of the Army Medical Service which followed the wholesale rejection of recruits because of physical disability. An investigation showed that the conditions responsible

for this physical decadence were directly attributable to poverty, that this in turn was due to the change brought about by the rapid rise of industrialism following the adoption of labor-saving machinery, and that in consequence of the prevailing poverty the children were being reared as weaklings, incapable of resisting disease and largely impervious to education. As a measure of relief for this deplorable situation the inquisitorial council recommended a school lunch service for needy children, to be maintained at the public expense. An examination of over 330,000 children (one-third of the school population of the city) by the medical inspectors of the New York Health Department in 1913 disclosed some 14,000 cases of malnutrition; and, on the assumption that the same ratio of this condition is to be found in the rest, there would be more than 40,000 children in the schools whose health is impaired owing to a malnourished system. It has been ascertained that in Cincinnati, of 36,438 children examined, 1619 were suffering from malnutrition; in Cleveland, of 61,578, 671; in Newark, N. J., of 27,971, 940; in Rochester, N. Y., of 18,497, 945; and in Worcester, Mass., of 18,342, 389.

While, of course, the provision of a suitable meal at noon is inadequate to overcome such malnutrition, the school lunch service is undoubtedly a palliative measure of great practical service, and one which can be made productive of a widespread influence for good. In the latest *Monthly Bulletin* of the New York City Department of Health there is published a valuable contribution on this subject by Edward F. Brown, executive secretary of the school lunch committee of the Association for Improving the Condition of the Poor. From this it is learned that the New York School Lunch Committee was organized in 1907 for the following purposes: 1. The provision of nourishing lunches on a self-supporting basis for public school children. 2. Special observation of children whose physical condition is such as to give evidence of lack of proper nourishment, in order to determine the underlying causes by a study of their homes and environment. An extension of this aim requires that these selected cases be followed up, to the end that the proper agency may be apprised and appropriate action taken. 3. The formation of special classes of mothers for instruction in the proper care of children, and particularly those suffering from poor nourishment. It will thus

be seen that the work of this committee is very much more comprehensive than the mere providing of nourishing noonday lunches. The need for a school lunch system, as Mr. Brown says, ought really to be regarded as a symptom of a serious social disorder. The necessity of feeding children at school usually arises from either a demoralized home, where the housewife has to work out, indifference of the housewife, or ignorance of home economics. The service of a noon meal is at best to be considered inadequate for a number of reasons, among which may be mentioned the following: Behind each child in need of such a service is a home lacking the facilities for proper feeding; for such a child the need is just as great for its other meals and for feeding on non-school days and in the summer recess; the presence in the family of children of pre-school age; the fact that any desirable effect resulting from the scientific feeding of the child at one meal time at school is likely to be destroyed by the kind of food it gets at home at the other meals. Properly, therefore, the feeding of children should be made part of a much larger social program. At the present time there are in New York twenty schools, registering 32,000 pupils, where the lunch system is operated. The need for such a service was naturally most urgent in districts where the people were impoverished, where mothers worked in factories by day, and where the children depended for food on the few pennies which purchased candy from the vendors about school-houses. An experiment was tried in the equipment of a kitchen in a school building, where soup, sandwiches, puddings and cocoa were provided at the rate of one cent a portion—the child being required to purchase first a bowl of hot soup. The caloric aggregates of some of the typical trays of food provided, the price of none of which exceeds a total of three cents, are given, and these are samples of them:—

Vegetable soup....	85.00	Bean soup.....	111.27
Egg sandwich....	236.00	Bread, two slices.	200.00
Rice pudding.....	108.76	Prunes.....	180.00
	<hr/>		<hr/>
	429.76		491.27

Aside from its other advantages, the school lunch system affords an admirable opportunity to teach the children the science of feeding, including the purchase, preparation and hygiene of food. Fundamentally, the work is devoid of any mark of poor relief. During the last school term 1,249,489 portions of food were sold; for

which the children paid \$12,494.89. The service was not quite self-supporting, for a deficit equal to a little over one-third of a cent per portion was incurred, and this was made up by a benevolent lady.

Naturally, in any scheme for feeding large groups of children, where the prime object is the rearing of a vigorous race, a scientific basis is essential. The working force of the committee is headed by a dietitian, who is responsible for the character of the food and service, and the principles on which food is selected are: (1) nutritiousness, (2) palatability, (3) purity, (4) seasonability, (5) inoffensiveness to racial or religious preferences, (6) similarity to home food, (7) balance in accordance with food principles. When the committee is assured that an article of diet meets with these requirements, a sample order of the raw product is secured, and it is then submitted to three tests: chemical, bacteriological and food value. Coöperation with the health department is stated to have yielded the most encouraging results. Analyses have been made by it, and also by some of the university laboratories. Furthermore, health authorities in other places have always aided when asked to inspect the manufactories in their communities. Where there is every indication that the product itself is pure, the place where the food is manufactured is inspected, and, in purchasing, preference is given to firms maintaining the best conditions. The social value of encouraging trade where decent conditions of work and welfare prevail is, it is felt, not only a just recognition of good public service, but a rebuke to the manufacturer who thrives on adulteration, over-work and under-pay; and here one recognizes another measure in the interest of public health, for in the degree that we demand livable conditions of labor shall we secure a diminution of incapacity, sickness and death. Where foods are found to contain harmful matter, or where the conditions of manufacture or sale are unhygienic, information is laid before the health authorities for action. This usually prevents the further distribution of a product which is likely to cause injury, and thus there is an educational advantage in this system which can scarcely be overestimated. An additional precaution to ensure the purity of the food dispensed is the careful scanning of the lists of convicted food adulterers prepared weekly by the health department. Of course, scrupulous care is taken to have the kitchen and service equipment entirely hygienic,

and in order to prevent the possibility of disease transmission in the preparation and handling of food, the committee had the health department make a thorough physical examination of all the school lunch employees, and also of a hundred children who assist in the service. The argument has often been advanced that the feeding of children at school causes shiftless parents to shirk their just share of responsibility in the nurture of their offspring; but this has not been found to be the case. On the contrary, the school lunch employees, coming in contact with the parents in the districts, are often consulted regarding what foods to prepare for children at home, and how to prepare them. Certainly, the New York School Lunch Committee is to be congratulated on the valuable and far-reaching work it is accomplishing.

SYPHILIS.

WE wish to direct the attention of every reader of these pages, whether man or woman, physician or layman, to the article by Dr. J. Harper Blaisdell which is printed in this issue, under the title of "The Menace of Syphilis to the Clean Living Public."

There is no doubt that many persons contract syphilis innocently and that many more are exposed to this danger. It has been pointed out that even those who lead the most sheltered lives are not free from this menace.

Must the innocent always be thus endangered, and how great is the risk?

Before answering these questions a store of accurate information must be collected.

Several years ago, as stated by Dr. Blaisdell, New York City made syphilis a reportable disease with this end in view. Statistics as to prevalence, distribution, and source of infection in a community must prepare the way for effective action.

Is it known how many syphilitics there are in our community, how many of them daily endanger their associates, or how many persons with lesions on the hands are engaged in the preparation of food?

These things cannot be known until all cases of syphilis are reported promptly to the local health authorities

Let us as physicians each and all prepare to do our parts in the campaign already being waged against syphilis, the tragic consequences of which we know full well.

THE QUESTION OF QUARANTINE TRANSFER.

IN previous issues of the JOURNAL we have, from time to time, commented editorially on the relative merits of federal and local control of quarantine service and, after discussion, have advocated the transfer of the Boston Quarantine Station from municipal to national administration. On March 23 the Boston City Council committee on ordinances reported favorably on the pending plan for effecting such a transfer, and it is expected that the necessary ordinance will ultimately be adopted by the council. At a meeting of the committee, the Boston Chamber of Commerce submitted a further report in which its previous opposition to the transfer was largely withdrawn. This report was based on a previous report by Mr. Robert Luce, chairman of a special committee of the Chamber, to whom the subject was referred. Mr. Luce's report expressed confidence that the federal government, in the event of transfer can be relied upon to provide adequate accommodations for detained immigrants and that the officials will afford the work as prompt and efficient a service as that which it at present enjoys. The final report of the Chamber further calls attention to the high local cost of maintaining quarantine service and the desirability of uniformity in quarantine administration from the point of view both of public health and of the commercial and shipping interests. The report continues as follows;—

"Furthermore, there appears to be reasonable ground for the expectation that in the near future it will be necessary to build a new detention hospital at Gallop's Island or elsewhere, and it is averred that the cost thereof may run as high as \$250,000. We were told it would be possible at present in case of emergency, to house nearly 1000 persons under roofs on the island. In the summer more could be maintained in tents, but it seems clear that provision ought to be made for winter conditions.

"If the United States takes over the station, it will proceed at once to make repairs under an

annual appropriation available for the service, and will proceed at once to acquire from Congress funds available for any new construction necessary.

"Manifestly it is important to the shipping interests that the quarantine station be adequately provided with personnel and equipment to handle vessels with the greatest possible expedition in ordinary times, and the least possible detention of the ship itself in case infection is found aboard. An outbreak of plague here would paralyze commerce by reason of attempts at self-protection on the part of other ports.

"Nothing indicates that our local quarantine service is not effective. On the contrary, it is praised. Yet whatever can be done to make it still more effective and to guard against every possible contingency would seem to be the part of prudence.

"The chief weakness of the present arrangement appears to be the usual weakness that follows a division of authority. Under normal conditions, all goes well. When the emergency comes and the second authority steps in, then come uncertainty, misunderstanding, friction, delay, economic loss, danger to the community. Unified administration lessens these chances of injury, and in that particular matter brings about certain specific advantages."

As the result of this reconciliation of the Chamber of Commerce to the proposed quarantine measure it is earnestly to be hoped that the transfer of the Boston Quarantine Service from local to federal control may soon be effected.

MISCELLANEOUS MATTERS OF MEDICAL LEGISLATION.

BEFORE the Massachusetts General Court, several measures of medical legislation upon which comment has been made in previous issues of the JOURNAL, have recently been acted upon as follows. The anti-vaccination bill was given leave to withdraw. The anti-vivisection bill was defeated by the House. A bill was reported by the committee on counties authorizing Barnstable County to construct and maintain a hospital for tuberculates. The public health committee reported favorably the bill requiring applicants for registration in medicine to be graduates from a medical school approved by the State Board of Registration in Medicine, or to possess an equivalent training.

The text of this important bill (House No. 745) is as follows:—

Section three of chapter seventy-six of the Revised Laws is hereby amended by inserting after the word "character," in the fifth line, the words:—and a graduate of a legally incorporated school of medicine,—so as to read as follows:—
Section 3. Applications for registration shall be made upon blanks to be furnished by the board, and shall be signed and sworn to by the applicants. Each applicant for registration shall furnish satisfactory proof that he is twenty-one years of age or over and of good moral character and a graduate of a legally incorporated school of medicine, and, upon payment of a fee of twenty dollars, shall be examined by said board. If he is found by four or more members thereof to be twenty-one years of age or over, of good moral character and qualified, he shall be registered as a qualified physician and shall receive a certificate thereof signed by the chairman and secretary. An applicant who fails to pass an examination satisfactory to the board, and is therefore refused registration, shall be entitled within one year after such refusal to a reexamination at a meeting of the board called for the examination of applicants, without payment of an additional fee; but two such reexaminations shall exhaust his privilege under his original application. Said board, after hearing, may by unanimous vote revoke any certificate issued by it and cancel the registration of any physician who has been convicted of a felony or of any crime in the practice of his profession. All fees received by the board shall, once each month, be paid by its secretary into the treasury of the commonwealth.

The committee on public health reported adversely on the bill and recommendation submitted by the State Board of Registration of Nurses. This recommendation contained in the fifth annual report of the board, was as follows:—

"The board recommends the passage of an amendment to the present act which will provide for the registration of two classes of nurses. The title R.N., meaning registered nurse, authorized for nurses who are graduates of approved training schools, and who can meet the requirements of an examination which would determine the fitness of a nurse to do any work a nurse might be called upon to do, and another title, that of H.N., meaning household nurse. Such nurses, with the title H.N., would, under this act, be permitted to take care of ordinary cases of illness, but could not nurse major surgical cases."

The defeat of the anti-vaccination and anti-vivisection measures is, of course, cause of congratulation to the medical profession. It is perhaps best that the bill on the registration of nurses should fail to pass at this time. It may

be hoped that that on the registration of physicians will have a more favorable fate, and physicians who favor it should write to their representatives and personally attend any further hearings upon the subject.

MEDICAL NOTES.

JORDAN MEMORIAL SANATORIUM.—The recently published second annual report of the Jordan Memorial Sanatorium, River Glade, New Brunswick, for the year ended October 31, 1914, gives an interesting record of work accomplished in the cure and arrest of tuberculosis. The number of patients admitted during the year was 87. Of this number six were discharged as cured, 13 as apparently arrested and 36 as improved.

POLIOMYELITIS IN DORSETSHIRE.—In a recent issue of *Public Health*, Dr. Rory McLaren, public health officer of Dorsetshire, England, records an acute epidemic of poliomyelitis in Beaminster, a town of 1700 inhabitants, eight miles from the English Channel. In this agricultural community the first case of infantile paralysis appeared on August 2, 1914. Sixteen other cases followed within a month, all within a mile and a half of the center of the village. Six of the cases died, five survived with serious paralysis and six recovered with slight disability. This typical severe outbreak conforms definitely with the infectious character of the disease and the probable method of its transmission by an intermediate insect host.

ADIRONDACK COTTAGE SANITARIUM.—The thirtieth annual report of the Adirondack Cottage Sanitarium, Saranac Lake, N. Y., contains a carefully detailed and interesting record of the work of that institution. Of the 229 patients treated during the year, 20.5% were discharged apparently cured, 43.7% were discharged with disease arrested, and 11% improved. The total contributions for the year amounted to \$63,620.67; contributions to the general fund amounted to \$14,432.71; to the x-ray account, \$3,100.00.

INCREASING DEATH-RATE FROM ORGANIC DISEASE.—The Life Extension Institute of New York has recently issued in pamphlet form an address by its president, Elmer E. Rittenhouse, entitled "America's Pressing Mortality Problem." Accompanying the text is a series of charts showing graphically the rapid increase of deaths from apoplexy, kidney and urinary disease and cardiac and circulatory disease in the United States and a corresponding decrease of

deaths from these causes in England and Wales.

In concluding his discussion of these facts, the author states, as his solution of this problem, that education in individual hygiene is the remedy for these alarming conditions and the ultimate means by which length and efficiency of life may be attained.

TYPHUS IN SERBIA.—It is reported by the war relief committee of the Rockefeller Foundation, on its return from a tour of inspection through Serbia, that typhus, typhoid fever, cholera, smallpox, diphtheria, scarlet fever, and recurrent fever are all existing in epidemic form. Typhus, the most deadly of these, already has caused the death of 60 out of 400 native doctors of the country. The foreign Red Cross units have suffered great losses. Two American units and one British have been compelled to suspend their regular work because of typhus. Nine American nurses and two physicians have contracted the disease. The Serbians assert that Austrian prisoners of war who were permitted to wander over the country, introduced the disease and infected the population.

ANNUAL REPORT OF THE CRAIG COLONY FOR EPILEPTICS.—In presenting their annual report to the Legislature of the State of New York, the board of managers of the Craig Colony for Epileptics, Sonyea, N. Y., make the following statement:—

"On September 30, 1913, the census was males, 763; and females, 664, total 1,427. There were admitted during the year 125 males, 86 females; total 211. There were discharged during the year 136 males and 81 females, a total of 217, making the census on September 30, 1914, 752 males and 669 females; total 1,421. From the time of the vaccination against typhoid fever of all employees and patients in the infirmary in 1912, no cases of this disease developed until in September, 1914, when three cases were diagnosed. It is believed that a carrier was the source of infection. The number of patients in the colony having tuberculosis approximates 200."

As is usual the report contains an interesting record of autopsies performed on 87 patients.

NEBRASKA ORTHOPEDIC HOSPITAL.—The seventh biennial report of the Nebraska State Board of Charities and Correction contains an interesting account of the Orthopedic Hospital maintained by that state. Since its establishment in 1905, it has treated nearly 1,000 patients. A new building for its use is in process of completion and when finished will increase the capacity of the hospital to 150 patients and make it one of the largest strictly orthopedic hospitals in this country. Its record for the two years beginning November 30, 1912 is 690 patients received, 279 discharged as cured, 258 discharged as benefited, 30 discharged as not improved and 16 deaths.

ANNUAL REPORT OF THE BATTLE CREEK SANITARIUM.—The recently issued report of the Battle Creek Sanitarium, Battle Creek, Mich., for the year 1913 shows a steadily increasing number of patients attending this institution and a constant broadening of the field of work here attempted. Since its incorporation in 1876, the number of patients treated has risen from 182 in that year to 5,693 in 1913. Improvements involving the expenditure of more than \$50,000 were made during the year. An advance in the work of the institution was initiated by the appointing of a committee to organize and equip a children's ward. In 1913 the number of patients aged 15 years or under was 176, the average number being 17.6.

In the first week of January, 1914, a Race Betterment Conference was held at the sanitarium, the expenses of the movement being borne by the Race Betterment Foundation, a philanthropic association which is closely allied to the sanitarium and which undertakes the support of numerous lines of philanthropic work directly or indirectly connected with it.

EUROPEAN WAR NOTES.—On March 27, the total of the New York Belgian relief fund amounted to \$995,579.59; the American Jewish relief fund to \$579,996.53; the New York Red Cross fund to \$475,350.34; the New York Committee of Mercy fund to \$137,523.71; the New York Polish relief fund to \$28,916.92; and the New York Serbian relief fund to \$25,217.00.

On March 28 the total of the New England Belgian relief fund amounted to \$238,503.92; the Massachusetts Red Cross fund to \$116,495.40; the Boston branch of the American Ambulance Hospital fund to \$56,348.25; the Boston Polish relief fund to \$38,775.87; and the Boston branch of the Prince of Wales fund to \$12,500.00.

BOSTON AND NEW ENGLAND.

EUGENIC LAW IN VERMONT.—Report from Montpelier, Vermont, states that on March 22 the Legislature enacted the so-called eugenic marriage law providing a fine of \$500. for any person who marries without a physician's certificate of physical and mental fitness.

MASSACHUSETTS DISTRICT HEALTH OFFICERS.—Notice was issued by the Massachusetts State Department of Health on March 23 that the eight new district health officers recently appointed by Dr. McLaughlin are to begin their duties April 1.

MILK AND BABY HYGIENE ASSOCIATION.—The sixth annual meeting of the Boston Milk and Baby Hygiene Association was held in this city on March 23 under the presidency of Dr. Charles W. Eliot. The principal address was by Dr. S. Josephine Baker on "The Community and the Baby." The annual report of the director

showed that during the past year 4,097 babies were treated at the 12 milk stations maintained by the association, whose nurses made also 50,275 visits to patients in the latter's homes.

ORGANIZATION OF THE EAST BOSTON MEDICAL ASSOCIATION.—On March 19, a number of physicians of East Boston met and organized the East Boston Medical Association. The following officers were elected: Dr. Frank Tilton, president; Dr. Robert Barney, vice-president; Dr. A. L. McLaren, treasurer, and Dr. J. D. Taylor, secretary.

EPIZOÖTIC OF FOOT AND MOUTH DISEASE.—At the Westboro Lyman School 61 hogs, valued at \$877, were found to be infected with foot and mouth disease following an attack of hog cholera, and were slaughtered. A herd of 70 cows kept near the hogs showed no signs of the disease.

MASSACHUSETTS HOMEOPATHIC HOSPITAL.—The recently published annual report of the Massachusetts Homeopathic Hospital states that during the year ended December 31, 1914, 23,260 patients were treated in the various departments of the institution, an increase of 808 over the previous year. In the wards of the Main Hospital there were treated 6,533 patients as compared with 6,508 a year ago. At the Haynes Memorial there were treated 838 patients as compared with 455 patients a year ago. The follow up system of the hospital has been enlarged and a social service worker engaged. The methods of fire protection over the hospital have been improved, \$3,442.89 being expended for this purpose. The report also contains a picture of the new maternity and out-patient building in process of erection, which will greatly facilitate the work of these departments.

LAWRENCE GENERAL HOSPITAL.—The thirty-ninth annual report of the Lawrence General Hospital, Lawrence, Mass., conducted by the Ladies' Union Charitable Society of that city, for the year ended September 30, 1914, shows that institution to be in a commendable state of efficiency. The total number of patients admitted to the hospital during this period was 1833. The out-patient department treated 1679 patients, and the orthopedic department, 558. The maximum number of patients in any one day was 93 and the minimum 46.

On October 8, 1914, Sarah Frances Shackford, the last survivor of the charter members of the Ladies' Union Charitable Society, died at her home, at the age of 75. She was at that time president of the society, having served continuously, in one office or another, since the organization of the society in 1875.

The hospital has been enlarged by the addition of a children's ward, the gift of Mr. Joseph Shattuck, and plans are drawn up for another building to be used as a nurses' home.

NEW ENGLAND BAPTIST HOSPITAL.—The twenty-first annual report of the New England Baptist Hospital, Boston, for the year ended December 31, 1914, shows that during the year, 12 patients were admitted. Of this number 105 received medical treatment, 499 surgical treatment and 70 were maternity cases.

The president of the corporation states in his report:

"The year just closed has been one of the most interesting in our history from every point of consideration. Our service to the community has been the largest, our receipts from all sources have been very materially increased, the amount of free service has been much larger than any year, with one exception, and the number of major surgical cases has been more than doubled, compared with former years, with a very gratifying low percentage of deaths."

CASES OF INFECTIOUS DISEASES reported to the Boston Board of Health for the week ending March 23, 1915: Diphtheria, 66, of which 3 were non-resident; scarlatina, 48, of which 7 were non-resident; typhoid fever, 6, of which 1 was non-resident; measles, 177, of which 2 were non-resident; tuberculosis, 53, of which 3 were non-resident. The death-rate of the reported deaths for the week was 19.12.

Correspondence.

PARIS LETTER.

(From Our Special Correspondent.)

TYPHOID FEVER IN THE WESTERN ARENA OF WAR.

PARIS, March 13, 1915.

Mr. Editor: In casting about in my mind for a heading to this letter I remembered the title of a book said to have once really existed: "English As He Is Spoke." So I propose to place as a supercription to the following remarkable document the thoughtfully ungrammatical sentence: "Typhoid fever she should *not* be took-care-of!"

In my last letter I referred to the universal dissatisfaction manifested here as regards the care of the sick and wounded from the fighting-lines. The main defence of the Service de Santé is that they have been utterly swamped by the number of men to be handled, which has proved to be in the proportion five to two, as regards the number they expected to handle and for which they had made provision. I also cited the somewhat peppery remark which a deputy claimed to have made to the director of this health service. Today I think I will give, nearly in full, a letter received from one of the temporary hospitals, to show that, perhaps, this deputy's sentiments are not altogether unjustified. When the war had been going on a few months, and the authorities saw at their antiquated nursing-system was giving such poor results, they decided to incorporate quite a body of properly-trained nurses from England into their sanitary formations, in the hope in this manner to leaven the entire lump of dough; arrangements were consequently made for the gradual moving across

the Channel of three hundred of these women, to be as picked a body as was possible under the present tight circumstances, the idea being to distribute them about among the military hospitals in little groups of four or five. The results of this move might really have been foreseen! The French voluntary organizations of amateur nurses,—who after all had been doing their very best, naturally,—were stung to the quick at this aspersion on their capabilities; they "saw red," as the expression goes, and in many places made the life of the English invaders a mild little kind of sheol, in which line of action they were often backed up by the medical attendants. So now the plan has been modified, and the endeavor is being made to place these nurses in groups by themselves, in such a way as practically to give them entire charge of the patients of whom they have the care. Among the first of these nurses to come over was an old friend of mine, a very bright woman of wide experience, and the following is the letter she wrote me soon after reaching her post. Comment on it is unnecessary. I will merely add that another nurse, to whom I showed this letter, tells me that she has seen a typhoid hospital of nearly one thousand cases, with conditions similar to these. I certainly am devoutly thankful that I have no son in this war. If I had, I might, perhaps, stand with fortitude his being killed in battle for his country's liberation; but what would *not* be hearable would be to have his life played with in this fashion.

"I am afraid you would be quite overcome by the awfulness of this place; it is a veritable pest-house we have got to, this time. There are eighty patients in all, and oh! what a desperate state they are in! This is only a temporary hospital, formerly a school, and the sick men are distributed about in different rooms. Up to the time of our coming there were only two real orderlies for medicine, temperature, hypodermics and cupping, two for giving the lotions, a sort of cross between a tub and a sponge, two for carrying up the food, and one on at night. You can half imagine the state we found the poor souls in. Up to three weeks ago the wounded were brought here; but now it is only for the worst cases of typhoid. There is a pump in the courtyard, and some warm water in the kitchen stove at times; but there is not a tap in the place, and every drop of water must be carried upstairs. The carrying would not be so bad, if we only had something to carry in: there is only one jug in the whole place (2½ litres), and although we ask, and are promised, we have not received anything further yet except five hygienic pails (there was only one when we arrived). There are just five basins for washing the patients,—five for eighty men! And not a pillow in the whole hospital, only little bolsters. There were only eight spitting-cups,—the men have been using the floor up to now; but by agitating we have been supplied with twenty condensed milk cans for this use. There is only one chair in each ward, and no bed-tables; so mugs, cups, everything goes on the floor, which is black, never scrubbed, only sprinkled with carbolic, as they do in the Paris Metro, and then swept with a wet broom, thereby grinding the dirt into the grain of the wood. The windows do not appear to have been cleaned since the building was put up, some fifty years ago. There is no place yet provided for disinfecting linen. I keep begging for formol, but apparently it is considered too costly. The mattresses are all old ones from the barracks, straw and lumps of wadding, all more than filthy and smelling frightfully, as you will understand when I tell you that they do not own such a thing as a rubber draw-sheet. The men seem so surprised when we want to change a sheet after an involuntary motion! The patients have been allowed to walk out of the rooms to the w. c., whether tottering and delirious or not, and when they are to have a lotion the orderlies have been making them leave their beds naked, go to the middle of the ward, and lay themselves down on a

cold wet sheet arranged over an India-rubber sheet on an ordinary stretcher. The lotions are ordered two, three or four times a day, and never at night, regardless of temperature, which is never taken oftener than twice a day. Nearly every patient gets quinine, and most of them are quite deaf from it. B-naphthol, aspirin, and cinchona wine are the regulation remedies, together with two kinds of hypodermics, caffein and camphorated oil,—a man up and about may be ordered a hypo of camphorated oil!

"When we first got here we all of us stayed on duty all night, to try and clean up the patients and make their beds. The men say one and all that they have not been washed for three weeks, or had their beds made. You cannot imagine what an awful state their mouths are in. I came on regular night duty on Sunday, and began with a death, a poor lad of only eighteen. I may say that the doctor is never to be sent for; he just comes once or twice a day, and lives in the town. This poor boy died in full view of all the patients, such a thing as a screen being unheard-of here, and after he died two orderlies just carried him away to the attic. As they were doing this a delirious man left his bed and was fumbling at the door, so that the orderlies had to put down the stretcher with the body on the landing and secure the wanderer. In the meantime several other patients were going to and from the w. c. and had to step over the corpse. It is all so gruesome, and so frightfully unhealthy,—little better than a pesthouse. The w. c. is on each landing, in full view, and consists of a wine-vat cut in half with a board across for a seat; they are, of course, in almost constant requisition!

"I cannot possibly continue for long in these conditions, with only one orderly to help me at night. We are also always short of disinfectant. If you could see me in this ward, with ten delirious cases, others coughing all the time, and others muttering! One feature about these men is curious, there seem to be so few bad hemorrhages; I wonder whether that can depend on the fact that many of them were inoculated on reaching the hospital? The majority are very serious cases, with bronchopneumonia, or pleurisy."

"S."

FIELD SURGERY ON THE POLISH BATTLEFRONT.*

KEMBLING, December 4, 1914.

Russian Poland near Lodz.

I am still alive in spite of being now four months in war. You can hardly imagine how sorry I was when I understood at that ominous Saturday, 1st of August, that I could not see you any more. For years and months I was looking forward with joy and happiness to seeing you at my house, and to having you for several days in Berlin, and then you were in Berlin and I could not even see you. The four months following that day were the most eventful of my life. Right away I was called to the front and was happy to follow and to obey this call. At first for about two weeks I was captain-surgeon in an old and famous dragoon regiment in Allenstein. There it was my duty to examine all the young and old fellows who wished to enter voluntary service. The court of the barracks was day by day crowded with men, not only with working men, but mostly with men of the upper classes. The enthusiasm was simply tremendous. It was impossible to take them all, although they insisted and begged, considering it as the greatest misfortune of their lives that they had not been able to be enlisted. Besides this business of examining I had to vaccinate all the soldiers of my regiment. You can imagine that this kind of work did not please me for a long time and after trying a

while I got another kind of work more like my specialty. I became captain-surgeon at a field hospital. Now I could work surgically and soon I went to the battle fields. My first experiences were at the little battle of Bialla, near the Russian frontier; they concerned, however, a very small number of wounded men, Germans and Russians. However, a few weeks later during the last week of August, I had the great luck of participating at the great battle of Tannenberg. I do not know how much you are informed of the events of this war, but surely you will know this tremendous historical event, one of the greatest victories of this war, where a relatively small German army captured a much bigger Russian army. Two weeks afterward I took part in the second great East Prussian battle "at the Masurian Lakes." The numbers of wounded men, both German and Russian, were overwhelming. We worked for weeks, day and night, at our field hospital. Besides this I had the special order after Tannenberg to take charge of one big Russian field hospital captured at Hohenstein. The work of a field surgeon is nowadays quite different from what it was formerly. Whoever expects to do great operations, amputations, excisions, etc., will be greatly disappointed. Conservative surgery is triumphing. I mean, of course, right away on the field and at the field hospital. Well adapted bandages, good fixation of the damaged joints and bones, plasters, and splints,—that is the point of field surgery, and not only of surgery of the extremities, but also in abdominal surgery it is much better not to operate in the field but later in the so-called "reserve hospitals," which are located near the boundary in a rather safe region. Therefore, again transportation plays an eminent rôle in modern war and motor cars are of tremendous use for war-sanitary-purposes. I presume that the triumph of conservative surgery in this war will be of eminent advantage for orthopedic surgery after the war. The two above-mentioned battles liberated East Prussia entirely from the Russian invasion, at least for several weeks and our army was free to enter Poland. The first expedition into Poland in which I participated went over Czenstochava, Radow, until very near Varsovie, capital of Poland. It was a march of tremendous laboriousness, the weather being rainy and cold during all the days, the streets of Poland being in an unheard-of condition, our horses being in morasses sometimes over their knees, and still we did not lose a single horse or wagon of our field hospital, and reached Warnhau or Varsovie, i.e. the neighborhood of this city, in less than twelve days, marching day and night with very little rest.

Nobody knows yet, with surety, what the idea of this quick march was and what the task of the return march has been which was made soon afterward. Surely it was not a flight, for we marched out of Poland more slowly than we marched towards Varsovie and surely the whole business was intended by our chief generals. For as soon as we entered Poland and we progressed, I had the exact order to send the wounded back to the frontier and not to treat them here. And every treatment had to be as fast as possible. For instance, in Grojeo, a little town near Varsovie, I had to bandage 450 men in one day and night, in order to fit them for transportation. The whole month of October we spent in Poland. As soon as we returned to Germany orders came for a second invasion into Poland from another point of the frontier. And now for three weeks our troops stand near Lodz, after having had some victorious battles on their way from Germany. We expect that these battles now will bring us the decision not only of the war against Russia, but of the entire war. It is true the Russians are much more numerous than we are, but this fact so far during the war was not of so great importance, the Russians thought. To my mind it shows enough the minor quality of the Russian army, that they were not able to carry war for any length of time into Germany. The point is,—and that I have a hundred proofs for,—the Russian soldier has

* Letter from Dr. M. Böhm, former director of the Medico-Mechanical Department of the Massachusetts General Hospital, to Dr. R. B. Osgood, of Boston.

idea what he is fighting for. You ask the captured and wounded,—and I have seen thousands,—whether they would like to return to their army if I dismiss them and they all will beg you to keep them. They all have a kind of stupid energy, but no intelligent enthusiasm whatsoever. Lately, during the last fights, the wounded Russians were often drunk. It seems that alcohol is used to drive them into the front. I personally believe we shall master the Russians in a relatively short time. Whether this means the end of the war, that, of course, depends largely upon other factors, particularly upon England. This is the most interesting moment in this war. Of course, you probably have your own opinion on this question and you will read in your papers and also in our papers great discussions upon the cause of the war. It is a pity to waste so much ink on this question. Nobody is the cause, history is the cause, general world conditions have brought it about.

I am afraid I have bored you too much with my talk. I have had four free days, living in a lonely Polish peasant house,—that may be my excuse. The purpose of my letter has originally not been to give you a political exposé, but simply to send you my warmest greetings and wishes for Christmas and New Year. I beg you, since I am unable to write Christmas cards, to give my regards to all my old good Boston friends, and my warmest wishes and greetings from your old

BÖHM.

P.S. If you know what it means it might interest you that since the battles in East Prussia I am "a knight of the iron cross."

QUESTIONS ABOUT THE HARRISON LAW.

BOSTON, March 16, 1915.

Mr. Editor: The new Federal law in regard to the dispensing of opium, the Harrison law, apparently imposes what I consider a dangerous limitation on doctors. For many years I have demanded that the druggist should write on the box a copy of any prescription which contained opium. This I consider a safeguard to the patient, and a help to the doctor. I have followed this practise since I knew of a case in which a mother gave a one-fourth grain morphine suppository to an infant to move the bowels. I recently criticized a reliable druggist who did not follow my directions, and was told that the Harrison law forbade such a practise.

It seems wise that the BOSTON MEDICAL AND SURGICAL JOURNAL should ask for a ruling on this question from Washington.

Respectfully,

HENRY JACKSON, M.D.

March 17, 1915.

Mr. Editor: Since writing the above, two druggists say they consider it proper to put the prescription on the box. They quote the rulings on proprietary medicines which demand this practise. Truly,

HENRY JACKSON, M.D.

[NOTE.—There is nothing in the Federal law which prohibits the prescription from being written upon the label of the container. The State law, however, provides that: "The prescription shall not be copied except for the purpose of record by the druggist using the same."

There is nothing in either law which prohibits the prescriber from giving whatever information or direction he may deem necessary for his patient to receive; and if he thinks it is best, he can direct that the amount of narcotic, which the prescription contains, shall be clearly stated upon the label. This can be done without a copy being made.

The following rules interpreting the Harrison Law have recently been issued by the collector of internal revenue, port of Boston and are reprinted here for the further aid and guidance of physicians.

"A physician, registered under the law, must keep a record of the drugs dispensed, distributed or administered by him in his office. A record is also required to be kept of those drugs left with a patient to be taken in the physician's absence. No record is required to be kept of those drugs personally administered by the physician to the patient when away from his office.

"A physician or dentist who uses only minute quantities of drugs affected by the act, such as oculists, aurists and other specialists, may keep a record of the date when a stock solution is made and the date when such stock solution is exhausted, without keeping a record of the name and address of each patient to whom such drugs are administered. Where a physician engaged in a general practise otherwise administers such drugs, it will be necessary for him to keep a record of the date when any such drug is dispensed or administered, the kind and quantity, and the name and residence of the patient.

"Hospitals and sanatoriums must keep a record of drugs dispensed, distributed, or administered therein.

"Government, state, county and municipal officers, lawfully engaged in purchasing drugs specified in the act for the army and navy, the public health service and for government, state, territorial, district, county, municipal or insular hospitals or prisons, are held to be exempt from the provisions of the act relating to registry and special tax, to purchase and use of such drugs and to the keeping of records. Any such officers, however, engaged in private practise must register, pay special tax and keep the records, and comply with all the requirements of the law and regulations."]

F. F. SIMPSON, M.D., Treasurer,
704S Jenkins Arcade Bldg.,
Pittsburg, Pa.

In an address delivered recently by Mr. Lindon W. Bates, vice-chairman of the Commission for Relief in Belgium, he said:

"The Commission was granted by the German Government not only the sole right to transport food into Belgium but given the active sympathy and aid of the German military authorities. Despite reports to the contrary, not one pound of food sent in has been appropriated. The treasury of the Commission draws from the generous heart of the world. Into this treasury has been put also all that the enveloped Belgian race could gather of the remnants of their shattered fortunes. It registers their struggle for survival. It represents their very all—the all that the better-to-do can give to help themselves and unreservedly to help their fellow being in the ranks already destitute and starving. This is our main purchasing fund—the greatest and the sacredest of all the donations."

The contributions made by the American doctors, through the Committee of American Physicians for the Aid of the Belgian Profession, are placed in the hands of the Commission, for distribution among the members of the Belgian Profession and their families.

Mr. Brand Whitlock, American Minister at Brussels, is credited with saying on March 17, that the food then in Belgium would not last longer than April 1.

UNITED STATES CIVIL SERVICE EXAMINATION.

The United States Civil Service Commission announces an open competitive examination for mine surgeon, for men only. From the register of eligibles resulting from this examination certification will be made to fill a vacancy in this position in the Bureau of Mines, Pittsburg, Pa., at a salary ranging from \$2400 to \$2700 a year, and vacancies as they may occur in positions requiring similar qualifications, unless it is found to be in the interest of the service to fill any vacancy by reinstatement, transfer, or promotion.

Graduation from a medical school of recognized standing, and at least two years' medical and surgical experience with industrial workers, are prerequisites for consideration for this position. Statements as to education and experience are accepted subject to verification. Applicants must not have reached their forty-fifth birthday on the date of the examination. This examination is open to all men who are citizens of the United States and who meet the requirements. Persons who meet the requirements and desire this examination should at once apply for Forms 304 and 2095, stating the title of the examination for which the forms are desired, to the United States Civil Service Commission, Washington, D. C.; the Secretary of the United States Civil Service Board, Post Office, Boston, Mass.; Philadelphia, Pa.; Atlanta, Ga.; Cincinnati, Ohio; Chicago, Ill.; St. Paul, Minn.; Seattle, Wash.; San Francisco, Cal.; Customhouse, New York, N. Y.; New Orleans, La.; Honolulu, Hawaii; Old Customhouse, St. Louis, Mo.; or to the Chairman of the Porto Rican Civil Service Commission, San Juan, P. R. No application will be accepted unless properly executed, excluding the medical certificate, and filed with the Commission at Washington, with the material required, prior to the hour of closing business on April 20, 1915.

NOTICES.

THE CUTTER LECTURE.

The Cutter Lecture on Preventive Medicine and Hygiene will be given by Joseph Goldberger, M.D., Surgeon, United States Public Health Service, Washington, D. C., on the subject of "Diet and Pellagra," on Friday, April 2, at the Harvard Medical School, 5 to 6 P.M.

These lectures are given annually under the terms of a bequest from John Clarence Cutter, whose will provided that the lectures so given should be styled the Cutter Lectures on Preventive Medicine, and that they should be delivered in Boston, and be free to the medical profession and the press.

The members of all classes in the Medical School, the medical profession, the press, and others interested, are cordially invited to attend.

BOSTON CITY HOSPITAL ALUMNI ASSOCIATION.

The annual meeting will be held at the Copley-Plaza on Wednesday evening, April 7, at 6.30 o'clock.

Dinner will be served at seven o'clock immediately after the business meeting. Dr. L. F. Woodward will preside.

A luncheon will be served in the hospital library at one o'clock to which members are invited by the Trustees.

WILLIAM H. ROBEY, JR., M.D.,

220 Commonwealth Avenue.

Secretary.

MASSACHUSETTS GENERAL HOSPITAL.

A medical meeting, open to the medical profession, will be held at 12 noon on Monday, April 5, 1915, in the lower amphitheatre of the Out-Patient Department. Entrance on Fruit Street.

1. Exhibition of Cases.
2. Dr. Roger I. Lee. "Splenectomy in Pernicious Anemia."
3. Dr. Oswald H. Robertson. "Urobilin Estimation in the Stools. Its Relation to Hemolysis."
4. Dr. Paul D. White. "Alteration of the Pulse. A Common Clinical Condition."

F. A. WASHBURN, M.D.,

Resident Physician.

SOCIETY NOTICE.

THE SOCIETY OF AMERICAN BACTERIOLOGISTS.—The Council of the Society of American Bacteriologists has decided to hold a special summer meeting in San Francisco, August 3, 4, and 5, 1915. The chairman of the local committee of arrangements is Dr. Wilfred H. Manwaring, Stanford University, California.

APPOINTMENT.

Dr. Philip J. Castleman has been appointed director of the bacteriologic laboratory of the Boston Board of Health, in succession to the late Dr. James J. Scafnell.

RECENT DEATHS.

DR. MICHAEL C. DRENNAN, who died on March 23, at Easton, Pa., was born in 1839. He served as a naval surgeon throughout the civil war and was retired in 1899 with the rank of rear-admiral.

DR. DANIEL J. O'SHEA, who died of pneumonia on March 23 at East Boston, was born there in 1876. He was a graduate of Boston College and studied at the Harvard Medical School. He is survived by his widow, two daughters and one son.

DR. AMOS PATERSON WEBBER, for 32 years a practitioner of New Bedford, Mass., died in that city March 20, aged 55 years. He was a graduate of Bellevue Hospital Medical College in 1883 and was a member of the staff of St. Luke's Hospital. He was a Fellow of The Massachusetts Medical Society and of the American Medical Association, and was prominent in Masonic circles. He is survived by his widow.

Address

THE PATRIOTIC AND HUMANE SERVICE OF THE RED CROSS NURSE.*

BY MISS MABEL T. BOARDMAN, WASHINGTON, D. C.,
*Chairman of the National Relief Board of the
American Red Cross.*

WITH the opening of the Twentieth Century, when in medicine the first thought is for the prevention of disease, and when the motto to be found in so many of our great industrial plants reads "Safety First," war seems an anachronism, an awful absurdity.

To depict the sufferings of the sick and wounded during military conflicts previous to the Crimean War would be but to repeat again and again tales of misery and horror almost beyond belief. Even under modern conditions the words of such an experienced soldier as General Sherman are not too strong to describe them—"War is hell!" It is a hell that only one who has been through the shock and brutality of battle, who has burrowed for months in the trenches with the soldiers, who has walked the interminable wards of suffering in the great military hospitals, who has seen the pitiful destruction and desolation of cities, towns, villages and countryside, and who has witnessed the wretchedness of shivering, half-starved prisoners can comprehend.

In the earlier days, men, though less humane than now, were not altogether brutal, and it is

with special interest that the Red Cross turns back the pages of history to the famous military nursing orders. They, like the Red Cross, sprang from the battlefield, for the Crusades gave them birth. We find at Jerusalem, in the hospital of St. John the Almoner, the cradle of the famous order of the Knights Hospitallers, of St. John of Jerusalem, of Rhodes and of Malta—orders that still exist. Fortunate were the sick and wounded who in those early days fell into the hands of these good knights. A woman's branch founded the hospital of St. Mary Magdalena in the same city, at the head of which was Agnes, a noble Roman matron. These devoted men and women we may claim as ancestors of the Red Cross Nurse. On the breasts of their armor or the shoulder of the long mantles appeared the cross, sometimes of white, sometimes of gold, sometimes of red; sometimes of one form and sometimes of another—but always the cross. These old Knights Hospitallers, though fighting for the Holy Land, never failed to give devoted care to all the sick and wounded, whether Christians or Moslems, thereby manifesting what to-day is the deep pervading spirit of the Red Cross—Neutrality, Humanity. This spirit of humanity broadened the scope of their labors. In the Eighteenth Century we find them aiding the victims of a serious earthquake in Southern Italy and Sicily, as did the Red Cross after the similar great disaster of 1908, in the same region.

Save for the volunteer aid of these military nursing orders, there seems to have been no attempt made to provide any nursing care in time of war. If the battlefield lay near some convent or town, the religious sisterhoods and other

* Delivered at the Graduating Exercises of the Massachusetts General Hospital Training School for Nurses on January 15, 1915.

kindly women of the neighborhood gave what help they could to the wounded within their reach. During the Thirty Years' War and the War of the Fronde, the Sisters of Charity, founded by St. Vincent de Paul, nursed the sufferers and also the victims of famine and pestilence, those two grim handmaidens of the God of War. Here and there through history are meagre stories of the work of patriotic and humane women for the sick and wounded of military conflicts. A thousand years ago after a battle, Haldora of Iceland called to the women of her household, "Let us go and dress the wounds of the warriors, be they friends or foes." Arras, around which lately there has been so much fighting, was the scene of Jeanne Biscot's labors for the sick and wounded in the siege of that same city in 1654. She and her friends established a hospital and continued their services throughout an epidemic.

How little, though, could such occasional, unsystematized effort mitigate the sufferings of the thousands and tens of thousands of the victims of war. Seventeen days after the battle of Leipsic, men were found who had died not from their wounds but from exposure.

FLORENCE NIGHTINGALE.

But new and forceful factors were soon to lead to a remarkable change in conditions. These factors were the telegraph and the press. The majority of those who witnessed the horrors of the battlefield were they who had taken part in the struggle and accepted conditions as the grim and terrible fate of war. Not so, though, was it with those at home, to whom the telegraph through the daily press brought the story of the misery, the agony of some wounded husband, father, brother, son or friend; for they saw in the suffering man of whom they read some dear one of their own.

Less than sixty years ago the cry coming from a war correspondent in the Crimea rang out one morning in *The London Times*: "Are there no devoted women among us able and willing to go forth to minister to the sick and suffering soldiers of the East in the hospitals of Scutari? Are none of the daughters of England at this extreme hour of need ready for such a work of mercy?" What had happened? Great Britain and France had united in 1854 to aid Turkey against Russia. Forty years had passed since Waterloo and deadened the memories of the horrors of war. So, proudly the English fleet with thousands of brave English soldiers had set sail. The nation had hailed with joy the victory of Alma; but close upon the news of victory came the reports of the uncared for sick and wounded men. The whole country was aroused. Mr. Sidney Herbert, then at the head of the War Department, wrote to the one woman in England whom he believed competent to relieve the situation, and while the post was carrying his letter to her, one from her to him offering her services crossed it on the way. When this, her country's call for help, came, before

even it was received in official form, Florence Nightingale responded. The supreme appeal of her life came to her, and she went to the Crimea. With her went thirty-eight nurses, called by "Punch," "The Nightingales," but by Kinglake, "The Angel Band."

This little group reached Scutari November 4, 1854, just before the battle of Inkerman. In the vast barrack hospital lay four miles of human misery, beyond all words to describe. Into these crowded wards and amidst these appalling conditions poured the human debris from the field of Inkerman.

French Sisters and Russian noblewomen were caring for their own soldiers, but at this terrible and chaotic moment Florence Nightingale stands out above all others because of her powers of organization, her ability to bring order out of chaos. Her sympathetic comprehension, her tact and good judgment commanded respect from officials who had seriously doubted the advisability of the presence of women in military hospitals. All the immense labor of organization never blotted out of Miss Nightingale's nature the tender, devoted nurse. At night as she passed through the long wards, her little lamp in her hand, to minister to the suffering men, they kissed her shadow as it fell across their pillows. Longfellow in his poem of St. Filomena says of her:—

"On England's annals, through the long
Hereafter of her speech and song,
That light its rays shall cast
From portals of the past.

"A Lady with a Lamp shall stand
In the great history of the land,
A noble type of good,
Heroic womanhood."

With Florence Nightingale we reach the turning of the ways. In the admiration for her great work for the sick and wounded during the Crimean War we are apt to lose sight of the foundation stone of her remarkable, patriotic and humane service; that stone was the training she had received at Kaiserwerth. There can be no doubt there were thousands of the daughters of England full of the same deep sense of loyalty and love for their country and her suffering soldiers. Love and loyalty must be the inspiration of all such work, but these are of little worth unless by the medium of the trained mind and body they can be made of efficient, helpful service.

Patriotic as were Miss Nightingale's individual labors, they accomplished an even greater work for humanity at large by their inspiration to others. When she was eight years old a boy was born at Geneva who was destined to accomplish great results in extending the efforts she had inaugurated in the hospital of Scutari. Henri Dunant while still a child interested himself in the works of charity and benevolence. The story of Miss Nightingale's work in the Crimean War had made a deep impression upon

him. In 1859, when northern Italy, aided by the French, fought to throw off the yoke of Austrian supremacy, occurred one of the great battles of history, the battle of Solferino; 40,000 killed and wounded was its deadly harvest.

Dunant, traveling simply as a tourist, witnessed the terrible suffering of the uncare for wounded. "The sun of the 25th of June, 1859, rose on one of the most frightful spectacles that the most vivid imagination could conceive," he later wrote of this battlefield. With the aid of the good women of the neighboring town of Castiglione, he organized a primitive relief corps. The wretched men—French, Italian and Austrian—were gathered in rough commissary wagons and carried to the small city, which itself soon became one great hospital. No organization of the Red Cross with its corps of trained nurses then existed to act as a medical reserve force, and even an attempt to cope with so much misery seemed hopeless. The wounded were dying of hunger for lack of those to minister to them. There were not enough even untrained hands to bandage the ghastly wounds. Cries and appeals for help filled the air and remained unanswered. Dunant and the good women did what they could; the latter, moving among their Austrian enemies, murmured, "Tutti fratelli" (all are brothers). Read scene after scene as depicted in Dunant's "Souvenir de Solferino" and wonder if nations must continue to settle their differences or protect their so-called honor at such a price as this. Dunant asks, "Would it not be possible to found and organize in all civilized countries permanent societies of volunteers which in time of war would render succor to the wounded, without distinction of nationality?"

Here had the Treaty of Geneva its inception, and the spirit of the Red Cross began to quicken into life.

Dunant followed up the success of his pamphlet by visiting the various countries of Europe, and succeeded in interesting a large number of prominent, notably royal, persons in his plan; first, for the acceptance of a treaty to protect those caring for the sick and wounded, and then in the organization of the volunteer aid societies.

The proposal to adopt a common and uniform flag to mark hospital formations was a welcome suggestion, for at this time each country had a different flag for its medical service. In Austria it was white, in France red, in Spain yellow, and in other countries black or green. The soldiers knew only the hospital flag of their own country, and were ignorant of the others.

In 1864 the Swiss Government addressed an invitation to 25 sovereign states to send representatives to a diplomatic convention to be held that year in August. Many of the military representatives at this convention were incredulous as to the possibility of securing the adoption of a treaty based on the recommendation of a previous conference. It was doubtless due to the

assurance of one of the American delegates, Mr. Charles S. P. Bowles, European agent of the U. S. Sanitary Commission, that many of the proposed provisions were similar to orders issued to our armies and which had stood the practical test of active warfare, that the Treaty was finally adopted. The Geneva, or, as it is sometimes called, the Red Cross Treaty, provides for protection for hospital formations and their personnel in time of war. Out of compliment to Switzerland, the Swiss flag with its colors reversed—a red cross on a white ground—was adopted as the great world-wide emblem of neutrality and humanity. As the noble work of Florence Nightingale had been the inspiration for Henri Dunant's splendid achievement, so had the practical labors of our own great Sanitary Commission helped to lay the foundations for the Treaty of Geneva.

In order to carry out the provisions for mitigating the suffering of the sick and wounded, the Convention passed resolutions recommending that in every country there should be a committee whose duty it would be in time of war to co-operate by all measures in its power with the medical services of the army. Among the proposed duties of such committees was the training and instruction of volunteer nurses to co-operate with the military medical authorities for active duty. Thus the ages have taught us the need for the patriotic and humane services of the Red Cross nurse. Not a Red Cross Society exists that does not recognize this necessity. Were there time, I should like to tell you something of what the foreign societies have done to provide this service. That there is room for improvement in many countries, in fact, in all countries, there can be little doubt. If through the medium of the Red Cross Nursing Departments a higher and more uniform standard of nursing can eventually be secured, a very important and humane service for all mankind will result.

One incident I may venture to cite to show how the need for the Red Cross nurse in war has benefited a nation in times of peace. In 1884, when the Japanese Red Cross was organized, there were no trained nurses in Japan, and there existed there a very strong prejudice against women of respectable character undertaking such a profession, but the Red Cross set its seal of patriotism and humanity upon the proposal. It instituted a training school for its nurses, and to overcome this popular prejudice, women of high rank took the required course. As a result, Japan has several thousand well trained nurses, not only ready for war or disaster, but for the daily service for the sick in the hospitals and in the homes. A group of these Japanese Red Cross nurses, with surgeons of the Society, has just passed through New York on their way to Europe to help care for the wounded there.

As part of the organization of the American Red Cross, there exists the National Committee on Red Cross Nursing Service. The chairman is Miss Jane A. Delano, to whom we are indebted

for a most efficient system; and many other prominent nurses constitute its membership. For enrollment in this service the highest standard ever adopted for nursing was established.

This Committee, with some 114 state and local committees, has enrolled over 5,500 of the best trained nurses in the country for active duty in war or disaster. No nurse is required to leave a patient, but in case of war or disaster if free to go she is expected to respond to the call for duty in her own country. For foreign service only such of our Red Cross nurses as desire to volunteer are sent. To the credit of our nurses, it is a great pleasure to report that no call has ever been made in vain; more nurses than required have always responded. Above the badges of their enrollment, the service bars of many of them testify to the fine sense of duty that inspires them. After cyclones at Hattiesburg and Omaha they cared for the injured. Scattered throughout the devastated flood districts of Ohio and the neighboring states, they not only nursed the sick, but they proved of incalculable value to the health authorities in the prevention of epidemics by their inspection and their instructions to the people. Promptly in the field, they donned rubber boots, waded through mud, and climbed over debris to reach those who needed their aid. At night they slept on a mattress on the floor or spent watchful waiting hours at remote stations to be ready for a sudden call.

Nor were the results of their labors to end with the relief, for some of the communities they aided, realizing the great help to the sick and their services to the health of the entire community, created visiting nurse associations to retain permanently the temporary benefit they had received.

After the Salem fire, thirty of our nurses were on active duty in the camps, the Maternity Hospital, the Contagious Hospital and headquarters. In the large camp at Forest River Park they mothered the whole community, looked out for the babies, gave lessons in their proper care, made many a wise suggestion about the children, inspected daily the entire camp; not only aiding in maintaining its health but leaving much practical information as the legacy of their work.

At Gettysburg and other veteran encampments, at inaugural and various other functions and parades all over the country they have maintained first aid stations.

Today amidst all the agonies caused by modern warfare, 150 of our Red Cross nurses are devoting their time, their energies and their efficient training to alleviating some of this appalling misery and distress. Our nurses may justly feel proud of their profession when they read the reports that come to the Red Cross of this work. Lady Paget writes that Queen Mary visited the Paignton Hospital, where our surgeons and nurses are stationed in England, and expressed her great pleasure over the efficient work they are doing there. Mrs. Whitelaw Reid, who has

been long interested in nurses' work, writes, "I am delighted with the way Paignton is run." From Pau the English wife of a French officer says in a letter to Mrs. Herrick, "The American Hospital is incomparably the best here, the only one where there is really trained nursing." And the wife of an English physician there says in a letter to an American niece: "The work of the American surgeons and nurses is beyond all praise. We cannot believe the other units can be as good as those sent here." The units sent to Germany each have a hospital near the Polish border. Mrs. Gerard, the wife of our Ambassador in Berlin, writes that the German Red Cross officials report they are doing wonderfully fine service and the seriously wounded are placed in their care. In Austria it is the same, one unit at Budapest and the other at Vienna. At Kiev, in Russia, the two units have a large hospital of 400 beds in their charge. When Belgrade fell into Austrian hands, the surgeon director of our unit there took under its protection the other hospitals of the city and their Servian personnel.

In the quiet efficiency of our Nursing Service, not only is suffering being alleviated, but, perhaps unconsciously, a missionary work is being accomplished. The services of Miss Helen Scott Hay, who is with the units in Russia, had been given by the American Red Cross to the Queen of Bulgaria for four years to organize a nurses' training school at Sofia on American lines. The sudden breaking out of the war has postponed this plan. Miss Delano, the chairman of our Nursing Service Committee, has been asked to supervise the training of a Greek nurse and one from the Philippines in this country. May this not be the beginning of a universal Red Cross nursing standard?

Nor have we yet reached the limit of the American Red Cross Nurses' patriotic and humane work. The Nursing Committee has organized classes for the instruction in elementary hygiene and home care of the sick, conducted by the Red Cross nurses, which will do much to improve the health conditions among our people throughout the country. A special department is devoted to the organization and training of a corps of town and county nurses, thereby extending the valuable services of the visiting nurse to small communities. The nurses of this corps must not only come up to the same high standards required for Red Cross nurses, but must in addition have taken at least a four-months' special course to fit them for their work.

Thus in the daily life or amidst the distress and destruction of great disasters or back of the tumult of the battle line the Red Cross nurse carries on her patriotic and humane service for her country and her fellowmen. This service must be a trained and organized service. All the sentiment in the world is of little worth unless training and organization can give this sentiment practical helpful expression. Yet through the practical and efficiently trained organization

must ever breathe the living spirit of the Red Cross.

"Some day," writes Charles Wagner, "the Red Cross will triumph over the cannon. The future belongs to the nurse, to the little grey sister, to all helpful powers, however humble; for two allies are theirs, suffering humanity and the merciful God."

A REPORT ON SOME CASES OF PERINEAL PROSTATECTOMY.*

By F. G. BALCH, M.D., BOSTON.

IN this paper I do not intend to discuss at length the merits of the perineal or supra-pubic operation but merely to give the results and a few facts in twenty-eight cases which I have operated upon at the Massachusetts General Hospital in the last two years.

I have included only my hospital cases in this list because they are the only ones of which I have accurate records, and because they are the only considerable series where spinal anesthesia was used. I have usually used ether in my private cases. My impression is that they would number about the same as the hospital list, and the mortality has been the same, that is, two cases out of about thirty.

One of my private cases, done before renal function was generally studied, and done by the supra-pubic method, probably would not have been lost by the perineal route. In the other fatal case, an intensely nervous man, I let myself be persuaded, because he had so much pain, that I had not removed the whole of the prostate. I opened up the wound again and he died within twenty-four hours. Temperature and pulse had both been normal up to the time of the second operation, and I found nothing to remedy.

In my hospital cases I have had two deaths, one in the first year and one in the second year. One of these deaths was from peritonitis caused by perforation of the sigmoid, probably by a rectal tube. The patient had been up and about for several days and death was in no way due to the operation. The other case was a Jew, seventy-five years old. He was more or less maniacal before the operation, pulled out his catheter, etc. Only one renal function test was done on him. As this gave a fair result I went ahead with the operation without doing a second test. I always intend to do two tests now. He had myocarditis, chronic bronchitis and emphysema. He also had cystitis and stone in the bladder. Not a good operative risk!

In the first year four cases of prostatic hyper-

trophy which were referred to me died without operation. They were never in a condition to warrant an attempt at prostatectomy. During the second year one case was not operated upon. He was a man of seventy-three who came in with acute retention. His renal function, done four times during his stay of over four weeks in the hospital, showed an appearance time of over forty-five minutes, and less than five per cent. excreted in one hour. At times his mental condition was poor, and he had eczema. At his own request he was discharged with instructions about self-catheterization.

Almost all the pathological reports showed glandular hypertrophy. In one case only was there adeno-carcinoma. The average age was sixty-eight, the youngest being about fifty-five and the oldest eighty.

Two cases had vesical calculi as a complication at the time of prostatectomy. One case also had a cancer of the breast which I removed under local anesthesia seven days after the prostatectomy. This man spent a long time in the hospital as it was almost impossible to get his renal function up to where I considered it possible to operate. The man was almost entirely blind, and had epididymitis eight days before operation and twelve days afterward.

Anesthesia was produced by intraspinal tropacocain except in four cases where ether was used. I had no untoward results from the anesthesia, whether general or local. In many ways spinal anesthesia is an ideal one in these cases. The patients are old men and it is well to avoid irritation of the bronchial mucous membrane. Again, they do not have to miss their breakfasts, can drink water immediately after operation, and usually are ready to eat in a few hours. The fact that this class of patients can drink water immediately after operation is a great advantage as old men who often have bad kidneys are altogether too liable to diminished renal output after ether anesthesia. It seems most unwise, after carefully keeping these patients on constant drainage for perhaps a week or ten days before operation to run the risk of decreasing the amount of urine just by means of general anesthesia.

In men with very atheromatous vessels the blood pressure drops very markedly in most cases, and there may be vomiting and what looks like severe shock. In this series of cases this was not seen.

I do not hesitate to use ether if for any reason spinal anesthesia is not available, in fact I have used it quite generally in my private cases.

In a general way the cases which stayed in for the longest time before operation, seemed to get out sooner than those that came through the accident room. This was not always the case. One old man of eighty came to the accident room with acute retention and was discharged with the wound perfectly healed twenty-five days after operation. The average stay in the hospital was twenty-eight days. Where there

*Read at a meeting of the Boston Surgical Society, Incorporated, February 1, 1915.

were no complications the average was slightly less.

Drainage tubes were removed usually on the second day. Patients were up in a chair from one to four days after operation, the majority being up in two days. Urine came through the penis in from two to fourteen days, usually on the fifth day. There was no trouble with urinary fistulae. In one case there was retention on the eighth day after operation requiring drainage for six days. In two cases, one on the third and one on the fourth day, the tube had to be put in again for a few days. In three cases there was epididymitis. One case had pyelitis on the fourteenth day.

In all these cases the median, perineal prostatectomy was done using the V incision with the point front. I prefer this method of approach to the central incision because I believe that by cutting off the raphe and pulling the bulb forward I can get about one half an inch additional distance that my finger can be inserted, and this is a very valuable half inch in some cases. I make no wide dissection of the base of the bladder but open the membranous urethra on a sound, and, pushing a finger forward through the prostatic urethra into the bladder, examine the prostate thoroughly. I then break through on the floor of the prostatic urethra, enucleating first the lobe on one side and then the lobe on the other. There is little trouble in getting the whole of the prostate. Counter pressure from above helps in some cases. Twice I have had a third lobe about the size of a horsechestnut drop back into the bladder. It is easily secured, however, with stone forceps. Small stones can also be grasped without trouble.

In the case of a very large prostate, it is sometimes necessary to bring it out piecemeal as the hole is not large enough to deliver a very large tumor. The operation is almost identically the same as the supra-pubic procedure, as far as enucleating the prostate goes. You simply break through the side of the urethra and shell it out.

Hemorrhage has been a negligible factor in all my cases. I put the double Eynard tube into the bladder and fasten it with a suture into the skin, holding it over into one angle of the V incision. I then bring the raphe into position again with buried chromic catgut sutures. Usually I put either a cigarette wick or a piece of rubber tissue into the other angle of the incision whence I removed the prostate.

These patients are put on constant irrigation after returning to the ward, and this is kept up from twelve to twenty-four hours, according to the amount of staining. The tube is usually taken out after twenty-four hours, the wick being removed a few hours before the tube. From then on, in the majority of cases, no instrument is passed into the urethra. In a few cases my house officers have put back the drainage for a few days, and in one case I had to pass a sound for the cure of a leak in the perineum.

Perhaps the most prominent advantage in these cases as I have seen them has been the lack of hemorrhage. There has been no necessity for any packing, rubber balloon or anything else inside the bladder to stop bleeding. I have not met with the supposed disadvantages of the perineal operation. I have given up the wide dissection of the Young operation, and the operative wound is hardly more extensive than with an external urethrotomy. Furthermore, there is no more danger of wounding the rectum than there is in the supra-pubic operation, nor are you any nearer to anatomical structures which you have to avoid injuring.

It is easy to remove the so-called median lobe, and, except in the case of a very large prostate, the gland can be removed entire. The same holds true of stones.

Persistent urinary fistulae which we have heard so much about, have not developed. The longest period of leakage was thirty-one days. Apparently a fold of mucous membrane made a valve obstructing the distal urethra. A sound was passed once, whereupon the leakage entirely disappeared.

Epididymitis occurs occasionally, but so it does in the supra-pubic operation. It is a simple proposition to do a vasectomy if anyone wants to make sure to avoid this complication.

Incontinence has not occurred in this series of cases, though one case, an old man of eighty-one, wears a urinal because he has some frequency and finds it more convenient than having to time his movements so as to empty his bladder when necessary.

A preliminary cystoscopy is most important for, of course, cases with diverticula, which need operation, and bladder tumors must be approached by the supra-pubic route.

ON THE FIXATION OF FRACTURED BONES IN INFANTS AND YOUNG CHILDREN.*

BY E. H. BRADFORD, M.D., BOSTON,
AND
ROBERT SOUTTER, M.D., BOSTON.

THE difficulties in the treatment of fractures of the thigh in adults are well known. It is not always possible to keep the fragments in exact position or to prevent some displacement from muscular action and to fix the limb absolutely. These difficulties are much increased where fractures of the thigh occur in infants. The action of the muscles is not as important a factor in infants as it is in adults, but owing to the small size of the bones, it is difficult to keep the fragments in place. This is especially true in the fractures of the upper third of the thigh. The

* Read at a meeting of the Boston Surgical Society, Incorporated, February 1, 1915.

different methods of clamping which have proved of service in many cases in fractures in adults are inapplicable to fractures in infants.

A simple method which proved of service in a two months' old infant deserves attention on account of its ready applicability.

The mechanical problem in attempting to steady two broken fragments of bone is not a difficult one and consists in an endeavor to fix both fragments firmly to a strong lateral, or side support, which will secure fixation in a desired alignment until solid union has taken place. The healing process can be confidently relied upon to occur under ordinary circumstances. The length of the side supports by which the fragments are held, manifestly is of importance, *i.e.* the longer the supports the better the fixation. That is, in case a long bone is broken, a clamp which is but half an inch long does not hold as firmly as one one-third or one-half the length of the broken bone. The conditions can be met in the following way: On two sides of the broken bone supports are fitted to which the fragments are fastened, reaching a considerable distance above and below the point of solution of continuity. This can be done by means which will not demand extensive dissection, which involves tissue trauma and the attendant muscular and tissue stiffening, prolonging the after treatment, by such a time as is needed to restore the tissues torn in dissection to normal suppleness.

The method has been employed in two instances, one in the fracture of the upper arm of a young child, and the other in a fractured femur in a two months' old baby.

By means of a long bone drill, with an eye at the point, the broken bone was pierced and strong 30-day catgut threads passed through the eye of the needle thrust through the skin. On withdrawing the needle the catgut is pulled through the bone. No dissection is necessary as the bone drill is readily thrust through the skin down to the bone. Palpation and the skiagram were sufficient guides for the proper placing of the catgut in the fragments of the bone. Any needed number of catgut cords can be passed. The skin is protected by a layer of fat-free leather, which will soften when wet and harden rapidly into stiffness. This leather soaked in alcohol is sterilized, and placed around the limb and the catgut threads passed through it. Small wood coaptation splints are then placed in desired places pressing on the side of the limb, one to check a forward and backward movement of the fragments, and another to prevent sideplay.

Traction is then applied to the limb, the coaptation splints held in position, the catgut threads passed through the fractured bone are tied to the coaptation wood strips, thus firmly lashing the fragments in proper position to a firm splint; over the whole a second layer of alcohol softened leather can be placed,

held by a firm bandage, and the limb secured in a wire splint. The leather softened in alcohol hardens quickly on the evaporation of the alcohol and in a short time the fractured limb was held in a firm leather splint firmly. The position can at any time be determined by skiagram. In the cases (young children) in which the method was used the leather splints and wood side splints were removed in four weeks, the catgut having softened and the fracture being firmly healed. The treatment involved no more complication than in the simple method formerly used, while a proper alignment of the fragments was secured without delaying the functional activity of the limb.

The method can not be regarded as one of fixation by clamps, but as one of fixation through carefully applied and secured coaptative splints. Though this method is especially applicable to the treatment of fractures in infants, it may be available in some fractures in adults.

Beside the proper apposition of the fragments it is necessary that the alignment should be kept during the healing of the bone. This is even more important than the exact apposition of the broken ends, and is of especial importance where the fracture is near the joints, especially the hip and the shoulder. The upper part of the femur tends to tilt upward, being pulled by the psoas and iliacus tendon. It is also pulled outward by the gluteus. Traction will only partly counteract this tendency and even if it were advisable to cut down from the bone, in infants and young children, screws holding clamps cannot be used for evident reasons. It is therefore necessary to place the limb in such a position that the lower fragment follows the line of the upper fragment; for this the ordinary apparatus, serviceable in adult fractures, is unsatisfactory.

Another consideration of importance is the need of securing the limb with as little bandaging as possible. The injury from interference with the circulation from prolonged bandaging is seen in adults. Atrophy of tissues, and degeneration of muscles are well known to occur from prolonged pressure. In addition to this there is, as has been proved by x-ray pictures, a change in the tissue of the bones in long bandaged limbs, which cannot be conducive to rapid healing. Plaster bandages are to be avoided as much as possible in infants and young children for this reason, and also from the fact that frequent inspection of the injured limb is important to be sure of proper position of fragments not easily held in plump and restless babies. Although it is possible to provide cut plaster bandages, furnishing a lid which can be removed when necessary, this in young children is met with some difficulty on account of the small bandages, which are liable to become soft and friable.

In joint fractures proper, *i.e.* in fractures in

the close vicinity and into the joint, present in young children complications due to a possible displacement of the epiphysis, a condition which is not always easily recognized, either by skiagraph or palpation.

X-rays passing through cartilaginous tissues fail to indicate the true condition of fragments, which, being small, are not easily recognized by the surgeon's sense of touch. While in adults these difficulties may be met by cutting down upon the injured part, securing the fragments as far as possible in a normal position, in infants and in young children there are manifest objections to this procedure. In fault of this, no method of clamping as suggested for fractures of the shaft being possible, the only recourse lies in all attempts to place the limb in such a position as will be best adapted to the restoration of a normal function. These may vary with the different joints, viz. the hip, shoulder, knee and ankle.

Hip joint fractures proper in very young children may be, in fact, epiphyseal tears, or separation of epiphysis, and can best be treated by means of an abductor traction splint used in the treatment of hip disease. It is desirable to prevent the development of a coxa vara, upward riding of the great trochanter, and an adducted limb. Resulting stiffness at the hip joint is best combated by efficient traction, which checks shortened cicatrization of capsule and ligaments.

In shoulder injuries, where it is desirable to secure as good function as possible, the humerus should be held abducted at the elbow, strongly flexed.

Joint and epiphyseal fractures at the knee require care to prevent backward displacement of the lower fragment if the hamstrings are kept on the stretch. This can be best accomplished by keeping the limb in a slightly flexed position at the knee, after carefully placing the fragments into as suitable position as possible by manipulation, with retention in the position of election by suitable and carefully adjusted and carefully watched pressure. This fracture needs constant inspection.

Joint fractures and epiphyseal separations near the wrist and ankle in children need no especial comment as the principles of treatment do not differ from that in adults. They need, however, frequent inspection and less prolonged fixation than is usually necessary in adults.

The treatment of joint fractures in young children should never be routine treatment, if the best results are to be obtained. Frequent inspection of the limb is needed, with at times frequent re-adjustment of pressure. It is for this reason that plaster of Paris bandages are less serviceable in children than in adults, especially in some fractures and injuries near joints.

The most serviceable appliances will be found to be ready-made wire splints, variations upon the well-known Thomas splints, which may be said to consist of a wire ring encircling the up-

per part of the limb, connected with two wire rods extending below, bent according to the case and united below.

The convenience of plaster of Paris is so great that surgeons are apt to rely upon this exclusively in the treatment of fractures, leaving the details of management of these cases to well trained assistants, and in large clinics this is usually the most practical way of the management of fracture cases. Complicated apparatus needs special training, which is not always obtainable, but simple apparatus, such as is applied by any well trained assistant, although supervision and direction will be necessary: The variations in size of these splints can be met by keeping on hand three or four sizes, as is necessary in the usual splints used for fractures of the upper extremity.

BORDER-LINE CASES OF MENTAL DEFECT, WITH SPECIAL REFERENCE TO HYSTERICAL SYMPTOMS.*

BY CHESTER C. BECKLEY, M.D., LANCASTER, MASS.

As our knowledge of mental diseases and defects increases and as we gain more skill in recognizing the symptoms to which they give rise, we are able to classify conditions which have not been understood heretofore. There remain borderline-cases which it is difficult to classify, or if they can be classified, for whom it is difficult or impossible to secure suitable treatment. Many times the more noticeable symptoms are those of the hysterical, but careful study reveals a mental defect, a beginning or mild psychosis as an explanation of the person's unusual behavior.

My experience has been gained at the Lancaster State Industrial School for Girls, to which delinquent girls under 17 years of age are sentenced by the courts. Under the present system, few, if any, are so sentenced until other methods have failed: probation by the court, oversight by the Society for Prevention of Cruelty to Children, the State Board of Charity, private charities, etc. Many have been examined by an alienist, who frequently reports that the girl is not normal but that the mental condition does not warrant her being sent to a feeble-minded school or to a state hospital. Frequently girls are sent to Lancaster who admittedly should go to a feeble-minded school, but cannot be received on account of lack of room. Many of the normal girls do well on probation or in the care of some society, and consequently never reach us. We have, therefore, at the Lancaster School, a large number of mentally abnormal girls, many of whom are high-grade defectives. The study of these border-line cases is most interesting. Their

* Read before the Boston Society of Psychiatry and Neurology, December 17, 1914.

aggerated reaction to outside stimuli, to pain and to mental changes, gives us, I believe, an insight into the same reaction, but to a less degree, in more normal people.

We have been able to secure exhaustive family histories in many cases, nearly all of which show bad inheritance together with a bad environment. In some instances the picture is so dark one wonders at there being such families in existence. The lack of discipline and the means which the child takes to secure freedom to gratify the desires of the moment have to be considered in the final analysis. It is easy to understand how a neurotic, wilful, disobedient child with a lack of self-control, who cannot appreciate the penalty she will have to pay for her transgressions, soon develops into an hysterical offender, especially during adolescence. Dubois says, "An hysterical person is an actor who has lost his head and plays his part, imagining that it is real." In discussing a tantrum or a convulsive seizure with a defective girl, I have been told frequently that in the beginning she was trying to gain some end, later she could not help it.

Doctor Savill in his "Lectures on Hysteria" has the following to say of the hysterical person: "These patients, even in ordinary circumstances, are easily roused to violent expressions of feeling, to hasty judgments, to impulsive actions, and to passionate exhibitions of various kinds. One moment they are angry because a thing is going to be done; the next moment they may be cross because it has not been done. Sydenham in 1680 described this mental instability well. 'All is caprice. They love without measure those whom they will soon hate without reason. Now they will do this, now that, ever proceeding from their purpose.' Briquet in 1859 went more on the emotional instability as being the chief feature of the hysterical mind, and without doubt it is a very striking feature. But in typical cases there is more or less instability of all the mental faculties—sensation, perception, memory, imagination, feelings and emotion, ideation and connotation, attention, judgment and will. The will power is variable and apparently insufficient to control the unruly thoughts, acts and emotions; but it has often seemed to me that this inefficiency is sometimes more apparent than real, by reason of the strength and unruliness of the emotions which the will has to control. All the faculties vary from time to time and thus again it happens that the hysterical mind is what we call an unbalanced mind."

"There is about all their vital phenomena, whether healthy or morbid, a variable or paroxysmal character, a change from day to day which seems quite peculiar to them. Whether ill or well, this is noticeable; and if suffering from some intercurrent malady, one day the patient is so ill as to be hardly able to move, the next day she may be up and about, although the malady has undergone no change. This sometimes brings them undeserved blame."

"Individually these qualities may not be very distinctive, but collectively—the impulsiveness, the emotional instability, the ready flushing, the excitable reflexes, and the variability of the vital phenomena—they are so far distinctive as to enable a careful observer to recognize the hysterical diathesis in the female sex."

I have quoted the above at length as it gives a clear description of a class of cases that are troublesome in an institution and that are unmanageable in the home. Most of the more marked cases of this type that I have seen are mentally defective, and a few, on account of their lack of control and the completeness with which they are mastered by their ungovernable temper, become dangerous to others and should, I believe, be treated as insane.

Malingering, simulation and the production of an abnormal physical state by some means which must cause physical distress, when there is nothing or so little to be accomplished that the discomfort is out of all proportion to any possible gain, seems to me to indicate an abnormal mental state. Threats of, and ineffectual attempts at, suicide, are common with the psychopath. I know of only two cases in which attempted suicide was successful. The first was an apparently normal girl, who had never threatened self-destruction. In going over the case afterwards, there was nothing to be found that might have led those in charge to suspect such an attempt. The other, a syphilitic girl, had had violent outbreaks and had threatened to kill others as well as herself, was probably insane, but we were unable to determine a psychosis. Many attempts have been frustrated, some of such a nature as to leave no doubt that they were not intended to be successful, others apparently so nearly successful as to be regarded as most serious.

Somatic influences play an important part. The large number of physical defects found in mental defectives and psychopaths is astonishing to one who has not had the opportunity of examining a large number. The list includes ear, eye, nose and throat defects, defects of the circulatory system, including functional and pathological heart conditions and vaso-motor instability, defects of the gastro-intestinal tract and the genito-urinary system, skin diseases, weak and fallen arches, asthma, glandular enlargements, poor teeth, poor nutrition, lack of resistance against infections, etc. Menstrual abnormalities are frequent, incontinence common. I have wondered if the internal secretions were not oftentimes out of balance. Many of the girls have enlarged thyroid glands, but as there is a physiological increase in the size of this gland during adolescence, and as I have seen a number of abnormally large thyroids in public school girls, who are otherwise apparently normal, I should hesitate to say that this was more frequent in the class of cases under discussion, without definite data.

I have been much interested in the theory

that vaso-motor defects may be the cause of hysterical manifestations. I have often been able to observe vaso-motor changes preceding and during an attack and have been able to get a history showing this defect in many others. The feeling of cold or heat on the surface of the body, the flushing or pallor of the skin which often precedes or accompanies an attack is very suggestive. Mottling of the skin has been so well marked in a few cases that I have had to watch the condition come and go in order to satisfy myself that the patient did not have a rash. The most profound vaso-motor paralysis I ever observed was in a girl who practiced self-abuse excessively, which I considered to be the cause. Whether or not we consider sexual trauma to be a cause of hysteria in the average person, it seems doubtful if it can be of great significance etiologically in a girl who will discuss her sexual indiscretions as freely and with apparently as little feeling as she talks about her school work.

The physical symptoms of which these girls complain are often most confusing. Many times slight discomforts and pains are magnified until they assume the proportion of a serious condition. Past illnesses are remembered and the patient apparently suffers as much from a second and a third attack, for which there is no pathological cause, as from the original illness. I have seen girls suffer from repeated attacks simulating appendicitis after the appendix has been removed. A girl repeatedly comes to the hospital, bent over, crying from a pain in her left side, to be cured in five minutes by being put to bed with a hot-water bottle. A history of the case shows that she had convulsive attacks several years ago, later, cyclic vomiting. At one time a girl would come to the hospital every few weeks with a febrile attack for which we could not account. The matron watched her very carefully and found that if she did not get an answer to a letter she had written within a certain time she would begin to worry, stop eating, and would have to come to the hospital. Twice she came to the hospital with a temperature over 101° as predicted after the letter was sent and no answer received. I asked for a report on a girl who had repeated attacks of acetoneuria and in reply got a statement that at certain times she would begin to worry, lose flesh rapidly, and after a few days have to go to the hospital. It often happens that a girl who has been menstruating regularly up to the time of coming to the school will not menstruate for months. At times the bowel functions seem to be in abeyance for days and occasionally the kidneys do not secrete for three or four days.

In selecting the following cases to report, I have taken those which best illustrate several different types that, in my opinion, need custodial care, and for which, with one exception, we have been unable to secure permanent treatment in a suitable institution. The first four cases are included to show the physical symp-

toms of which the defective delinquent may complain. If I have not given sufficient data to demonstrate the defect it is because I wished to keep the record within reasonable bounds, not because the material is lacking. One case, No. 6, is included to show the development of a psychosis in a mentally defective person.

CASE 1. A. M. Born August, 1892. A foundling, adopted from the State Board of Charity. Character of home, good. Her mother by adoption, respectable, has but little force of character. Mother's second husband died when Alice was thirteen years of age, since which time Alice has been unmanageable. Alice associated with low boys and girls. Worked for a short time in four places. Ran away from home and hired a room to which she brought men.

Committed to Lancaster in May, 1907. Examination showed eye and ear defects. She was infected with syphilis and gonorrhea. Has had diphtheria and appendicitis. Reflexes normal. At the School, was always in trouble; no violent outbreaks or tantrums, but always doing foolish things and getting the other girls into trouble. Dared a girl to eat the eyes out of a frozen cod fish and when the dare was not taken, did it herself. Would get food out of the kitchen and eat an enormous quantity. Stuck needles into herself until we refused to cut them out. At one time claimed to have got glass in one eye; we picked out pieces of glass for several days. We finally told her that if she put any more glass into her eyes it might stay. At another time she said her bowels had not moved for two or three weeks. More recently has complained of "blind staggers." Has fainted.

October, 1911, was given neo-salvarsan at the Boston Dispensary. Following this her arm and hand were swollen and gave her a great deal of pain for six or seven weeks. Examination and x-ray negative. There were suspicious marks above the elbow. She was accused of cording her arm. This she denied, but soon after told of falling out of a chair and striking on her elbow, after which she felt "pins and needles" in her hand. The hand got blue and the swelling subsided—recovery immediate. June, 1913, was given neo-salvarsan intravenously. She became delirious, then unconscious, these states alternating for several days. There was no secretion from the kidneys for thirty-six hours. The nurse reported that while in a hot pack her breathing stopped and her pulse became very weak.

At another time she developed some trouble with one knee—pain, redness and stiffness, and at times slight cartilaginous crepitation. The redness looked very superficial as if it had been encouraged. This lasted for several months; part of the time she was in bed.

Occasionally her work was satisfactory, but most of the time she was not interested in it and needed constant supervision. She was easily discouraged, impressionable, and was always looking for excitement.

When placed on parole she did not do well. In one place she left the baby alone, took clothing and disappeared. Was found living with a boy. After this, several unsuccessful trials. Was arrested for larceny. When she became twenty-one she went to live with a man whom she had married at some previous time, and of whom she had claimed to be very fond, but she soon tired of him and went to

live with another man. When last heard of, was at the State Infirmary awaiting confinement.

Diagnosis. Although she passed the Binet test for fifteen years, I believe she is a defective delinquent and should have custodial care. There is a probability of cerebral syphilis and the knee may have been organic.

CASE 2. E. B. American parentage. Born November, 1893. Committed Dec., 1908. A police officer reports: "The father is poor stuff and has been on our books and graced our docks many times for drunkenness and non-support. Husband and wife living apart. They move frequently, either the house does not suit the B's or the B's do not suit the landlord. The mother is in poor health; her character has suffered on account of her fondness for men. E's sister is noted for her indifference to her marriage vows. The home is very unattractive and on the whole E. cannot be good and nothing can be expected of her people to aid her future."

A report from the Associated Charities: "From first to last the church has done a great deal for Mrs. B. We have dealt with three families related to her; very poor stock, epileptic, feeble-minded and drunkards." The mother's sister, who lives with the B's, is a notorious character.

Before coming to the Lancaster School E. had lived a disreputable life—a sexual offender, drank, smoked and probably took drugs. As it is the influence which her mental state had over her heart's action which I wish to bring out, I will not take time to go into her mental history, excepting to state that she is a high-grade mental defective, and is very susceptible to her surroundings. She passed the Binet test for eleven and four-fifths years when she was seventeen years old. She can and does do her work very well when interested in it. When not interested, her work is far from satisfactory and she complains of heart pains, weakness, dizziness.

She had rheumatic fever in August and again in December, 1907. Chorea, lasting one month, the same year. Has had follicular tonsillitis, measles, and scarlet fever. She has a double mitral lesion, an hypertrophied heart and evidence of kidney involvement. After coming to Lancaster she did not menstruate for six months. She complained a great deal of pain in the region of her heart, shortness of breath and dizziness. June, 1910, she was in the hospital suffering from failing compensation. There was considerable cyanosis, dyspnea, and a small irregular pulse. The heart, which was very large at best, seemed to be increasing in size. No treatment was of any use. The condition seemed so serious that I advised the authorities to allow her to go home provided she should improve sufficiently to be able to stand the journey. She was told that she could go home when she got better. The result was that within a few days she was sitting up, apparently as well as ever. The authorities were suspicious that I had over-estimated the seriousness of the case and withdrew their permission. Within a week or ten days she was back in bed with all her old symptoms. Her condition became so serious that she was again placed on the dangerous list. This time I told her, myself, that if she got better she should surely go home. The result was nearly as prompt as before, and she was allowed to go.

She remained at home for a while, then ran away and lived in a very dissolute way. Was returned to the School. She did not have as bad attacks after this, but was not able to do any work. Was in bed

a great deal. She was sent to the State Infirmary for treatment. She improved and was returned to Lancaster. She was better for a time, then became discouraged and lost all she had gained. We took her into the hospital and after a short time began to have her help in the kitchen. This seemed to interest her and soon she was doing as much as any body and continued to work until she became of age and left the School. I believe the care which she received at the house in which she lived was as good as that at the hospital, but she did not like it. No treatment with drugs seemed to relieve her to any great extent, and at times heart stimulants made the pain worse.

Remarks. If I had not had this experience and watched this case for several years I should not have believed that the mental state could affect the action of a diseased heart as it apparently did in this case. It has made me hesitate to join in the criticism which we frequently hear of physicians who, from the subsequent outcome of the case, have apparently overestimated the seriousness of a prisoner's physical condition, thus securing his release.

CASE 3. E. B. French Canadian. Born May, 1895. Father alcoholic, abusive, sex offender, has court record. Mother tubercular. Brother and sister said to be "unusually smart," have but little respect for parents. A brother arrested for breaking and entering. Emma said to be stubborn and unmanageable at home, lies continually, out nights with questionable girl friends. Is a trouble maker, tells one girl what another one said about her and so on, until she makes a complete tangle and confusion. She has stolen twice and frequents cheap dance halls.

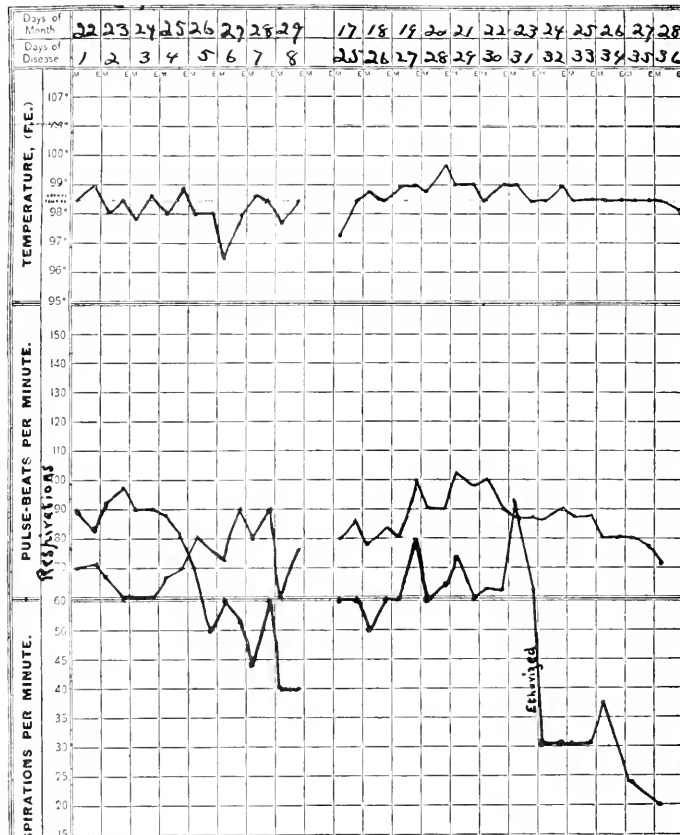

Committed to Lancaster, September, 1911. Physical age, sixteen years; Binet age, ten and one-fifth.

Physical History.—"An attack of heart failure one year ago." Sick two weeks. No other illness. Heart normal at time of first examination. On Sept. 22 she came to hospital complaining of difficulty in breathing, pain in pericardium and across upper part of chest. This of several days' duration. Respiration very rapid (90). While waiting to see the physician she became faint and had to lie down. There seemed to be considerable prostration, hands cold, pulse rather compressible, but not rapid; examination of chest was unsatisfactory on account of the rapid respiration. She had times of coughing and choking. A tendency to general convulsions, hands clinched, arms and legs straightened out. She did not seem disturbed mentally. Said, "If I could eat I would be all right." Reflexes normal. Test of sensation not satisfactory as she would say she could or could not feel, apparently at random. Urine normal. A possible cause of the above attack was that her plans to run away had been frustrated.

The rapid respiration continued for about four weeks; some days she seemed better, others not so well. Attempts to catch her breathing less fast while asleep and off her guard, failed. She complained of a varying amount of pain in the pericardium. There was a very sensitive area near the apex of her heart. She complained of "pin pricks" in her fingers and toes. There were no convulsions after the first few days. She was up for a time but seemed so weak and miserable she was put to bed. Her appetite was variable. She gained in weight.

Oct. 22, she began by having a slight cough, then screamed with pain, clutched herself over heart, pulled and tore clothing. Stiffened out with paroxysms of pain. Respiration 92 and irregular. Cried out for her mother. It was rather difficult to make her answer questions. Hands and feet were cold, left lower chest very sensitive to touch. A consultation was called and she was etherized for diagnostic purposes. Under ether respiration became normal. Heart sounds were normal. During recovery from the ether she vomited an enormous amount of partly digested food, two hand basins nearly full. She was given a severe talking to on the error of her ways. There was no recurrence of the difficulty. We have no further history because she ran away, and, although she has been heard from

ilitic, had gonorrhea and acne vulgaris. At this time gave a history of having had fits since she was fourteen years old. June 25, 1912, had tonsillitis. July 1, was found in a chair with head resting on window, unconscious. She remained unconscious for one-half hour, then had a convulsion which left her dazed. She slept most of the afternoon. Following this she had one or more convulsions every day for seventeen days. As convulsions come on there are clonic spasms of the arms and legs, hands are clenched, thumbs inside, feet extended; her head is suddenly jerked back and to the right shoulder, the left shoulder drawn up. Her muscles then become set in the position in which she happens to be. One day her head was hanging off the bed when she became rigid, and when moved back onto

several times, she has succeeded in keeping out of the way of the officers.

Diagnosis. An unusual hysterical manifestation, with acceleration of respiration to an extreme degree, occurring in a mental defective.

CASE 4. E. B. Italian. Born April, 1896. Father alcoholic. Mother a spiritualist, in good health before E. was born. E. weighed four and one-half pounds, normal infancy, had measles, chicken pox, German measles, whooping cough and hemorrhage from nose. Was not considered nervous. A friend of the family said that she remembered Elsie and that her bold actions were a menace to the neighborhood. She said she had fits in school. This is the only evidence that I have been able to get that E. had any convulsions, fears or hallucinations before she came to Lancaster.

Committed to Lancaster June, 1912. Was syph-

the bed she was in opisthotonos. Left cheek is drawn in. When convulsions begin to pass off, patient swallows, hands and feet relax, eyes look first one way then another. She goes from one convulsion into another. Has had three in forty minutes. During convulsions eyes are closed, pupils rolled up out of sight. When pupils can be seen they are dilated. When she recovers she begins asking questions. One day asked what time it was. When asked to say what time she thought it was, the patient answered correctly, although she had been having convulsions for two hours. At other times she seems dazed, mistakes people. One night fell and struck her head during a convulsion. At another time her face was contorted and she looked diabolical.

July 17, during the rigid state of a convulsion, an ether cone was filled with ether and put over her face. After what seemed to be a long time the patient began to struggle. She was told that if she

would straighten out, put head on pillow, and lie quiet the ether would be removed. This she did. She was given a long talking to, told that she could stop the convulsions and that she must or the nurse would give her something that would make her very ill. Every day for about a week she was told what would happen if she had any more convulsions. She has not had another and it is now eighteen months. Reflexes rather dull. Stands with eyes closed, but there is some unsteadiness, area of anesthesia varying, circulation poor. Passed the Binet test for ten years when she was seventeen years old.

Patient's own story. She does not know her father. Her mother has times of being dizzy, "is rotten inside," has had an operation. There is no one else in family who ever had fits. Since she was eight years old she has had attacks of nausea and vomiting. Since she was ten years old she has had cramps in abdomen once, twice or three times a week. She has had sexual relations with landlord since she was ten years old. He told her that she could get anything she wanted, at home, if she would have a fit. She did not know what he meant until one day she was picking lilacs, when a dog came up behind her and barked; this frightened her and she threw up her hands over her left shoulder. Her mother came to the door and cried out "Elsie is having a fit."

She had her first fit the first day of her first menstrual period. She stooped over to tie her shoe string, was unconscious one-half hour. She was anointed by a priest. After this she had a fit nearly every day. Days she did not have one she was sick at night—buzzing in ears, dizzy, nauseated and, if she got up quickly, was faint. Attacks were worse and more frequent before and during menstruation. She was dismissed from school and lost places in which she worked on account of fits.

She does not usually know when an attack is coming on; occasionally her head gets dizzy, she feels as if everything was going around and as if she was going around herself. She feels as if she was going to fall forward but does fall backward. Once she fell on a stone wall and cut her head; at another time she bit her tongue. She has cut her nose and hurt her knees. At times she gets cold, at others hot, before an attack. She does not cry out, but occasionally tries to talk, this she is unable to do as her tongue is numb.

During an attack she does not know what is going on about her. One day she thought she saw her step-father, who is dead, in a casket of plaster of paris. She sometimes wets herself and occasionally her bowels move while unconscious. She bites her left cheek. She has been told that she frothed at the mouth, and that she gets yellow and black in the face. She never has a headache excepting when coming out of an attack, then there is a pain which feels as if something was pulling from one side of her head to the other, pressure causing it to become more severe. It is because of this pain that she grabs her head at this time. After the attack passes off she sometimes knows what is going on about her, at other times she feels dozey, numb or nauseated. She has had as many as four in one day. She woke up one night and thought there was a statue in her room; she tried to grab hold of it and grabbed the door. Another night she thought her sister came into her room; she tried to grab her, caught the lamp and set fire to the house.

She now says (eighteen months after the above was written, during which time she has not had any

convulsions) that she had no fits before coming to the school, only faint spells; that her landlord had told her that if she did not like the place to have fits and she would get sent somewhere else. At first she made the fits, later she could not help having them.

Matron reports that she has improved. At first had tantrums, would swear, talk obscenely and threaten suicide if things did not go as she wanted. Would take things which did not belong to her. She is an inveterate liar; she can do housework if she wants to, but requires a great deal of directing.

Diagnosis. Hystero-epilepsy occurring in a mentally defective, syphilitic patient.

Remarks. In taking the above history I tried not to suggest anything to the patient, and some of the questions I put in such a way as to draw out the opposite answer if her answer were suggested. I believe the history she gave me at first to be the correct one. This case shows, I believe, the evolution of the convulsive attacks, which were more or less deliberately induced at first, later becoming sufficiently established to require outside assistance to stop.

CASE 5. A. P. A Russian Jew. Born January, 1895. Massachusetts.

Family History.—Parents, brothers and sisters, intelligent and respectable. Father is much upset and discouraged by actions of A. Loses his temper when dealing with her. Strikes her and pulls her hair. Home conditions good.

Past History. She was put on probation between April 29, 1910, and June 6, 1911. A report of her probation covers fourteen pages. There were seventeen people interested in her besides the Children's Aid Society. She was entered at the Emerson College of Oratory as a special student, given lessons in music, instructed in voice culture, work was found for her in stores, etc. She was allowed to return home. She ran away, was with a theatrical company. She was restless and discontented, would not stay in any one place and her conduct with men was questionable.

She was finally sent to Lancaster on June 6th, 1911, as there seemed nothing else to do. Our experience with her was simply a continuation of what had gone before. At the School her conduct was good. She was intelligent, clean and neat. Seemed quite superior in her manner. Was not much of a worker. Cheerful at first, then became depressed, feared she was going insane. Had times of being apprehensive. She complained of nervous tension, that she lost her self-control and said things she did not intend to. At times she was told of things she had said that she did not remember saying. She frequently forgot what had happened during certain periods of from one-half to three hours or more. Never forgot her name. She found letters which she had written that she did not remember writing and that were not sensible, that is, they were about things which had never happened. At one time, before coming to the school, she thought someone was trying to poison her by putting something into her food. Soon after coming to Lancaster she was visited at night by a lot of people, some friends, some otherwise. She said that she attempted suicide once by jumping into a river. Physical examination negative.

She was sent to the Psychopathic Hospital for observation July 30, 1912. They report: "While

here she conducted herself in a fairly normal manner and observation revealed no evidence of any psychosis, neither did she show any definite mental deficiency. She impressed us as a rather peculiar, unstable girl and that her difficulties have been due to her unusual temperament rather than to definite mental disease. Her stories in regard to her dealings with men of which you spoke seem to us unreliable and it would seem to us that untruthfulness on the part of the patient would explain her supposed difficulty much better than mental disease. Our diagnosis was psychopathic personality."

Sept. 26, 1912, placed at housework. Did very well for a while. Began to be very moody and depressed, at times hysterical. Expressed strong feeling that the Almighty had planned her life work, which was the stage. Dec. 13, 1912, place changed. Started in doing very badly. Seemed to be dreaming most of the time. When asked why she did not do better, said she was on the stage most of the time acting heavy parts. When she played a happy part everything went well. Her play at that moment, she said, was one in which she had become engaged and her engagement broken, which meant that she could do nothing well.

Feb. 17, 1913, home. Claimed to have been bitten by a dog belonging to employer's neighbor; brought suit which she won.

May 9, 1913, threatened suicide at her place of employment. November 29, 1913, permission was given A. to go from town to town as a "crew manager" for a periodical circulating company. Later had an attorney arrested for seduction on promise to marry, claiming that she was six months' pregnant, and that he was responsible. Evidence was given that she had been with other men, one of whom she had attempted to blackmail; that she had used morphine and been in the habit of drinking absinthe. A letter dated August 21, 1914, from a commissioner of charities of a city in another state, states that an examination disclosed that she was six months pregnant and suffering from gonorrhea. He also writes that she has no visible means of support and in his opinion is a menace to society.

She was brought back to Massachusetts, and again sent to the Psychopathic Hospital for observation. They report as follows: "Mental examination—Patient is nervous and impulsive and inclined to worry. Seems to lack ambition and sense of duty to other individuals and the community. Psychological examination: Actual age of patient, nineteen years; according to Binet, twelve and two-fifths years; according to point scale, fifteen years. Patient passes tests like any normal person, and gives no evidence of deterioration or mental defect. Comprehension, reason, judgment, planning and discrimination good. Patient has well-developed learning ability and remarkably good comprehensive memory. Constructive and analytical ability is good. Planning is very quickly done. Perception of form is adequate. Apperception is good. Patient is well oriented, has good general knowledge, and appears able to profit by experience. Reads quickly and shows strong interest and good attention. As brought out by examination, the only mental quality that may possibly functionate to the disadvantage of the patient is a slight suggestibility. Diagnosis: Not insane, not defective."

Remarks. I believe that the diagnosis of psychopathic personality describes this case as well as any. Although, as is stated, she appears able

to profit by experience, she does not seem to have so profited. I would like to raise the question of there being a moral defect in this case without there being an intellectual defect. I believe that this girl needs treatment, and that she should have custodial care. Attempts were made to secure treatment in sanatoria, but these failed as the authorities did not feel that they could control her.

CASE 6. B. S. Canadian parentage. Born July, 1895, in Massachusetts. An only child.

Heredity—Paternal: father and two paternal uncles, somewhat lacking in energy, but family shows an average of fair ability and industry. Maternal: mother hysterical, tuberculous; one uncle, sex offender; three uncles, tuberculous; one uncle and three aunts, neurotic; two great uncles paralytic; four cousins, sex offenders; thirteen cousins, tuberculous. All highly nervous and overbearing.

B. was from an early age very peevish and wilful, and everything that her mother and aunt could do to spoil her was done, partly because of their fondness for her and partly because there was no living with her unless she could run things. She was stuffed with candy and rich food, overdressed, and the household ordered completely according to her whim. They abetted her in deceiving her father and the teacher. In school, patient showed herself slightly below average in ability, was surly, deceitful, and cordially hated for her overbearing ways; usually chose rough and younger companions whom she could dominate. She had convulsions while teething, and later a severe attack of pneumonia. Later, when she grew very fat and clumsy, she was laced tightly in order to give her a trim figure. She then began to have fainting spells.

Her mother became very ill and they moved to a large farm, where she ran absolutely wild. Her mother died and she went to live with a married aunt, whose husband undertook to give patient some much needed discipline. She was a big, hoydenish girl, crazy to be on the streets with boys and rough associates, and refused to do anything at home but out-wit and tantalize her uncle in every possible way. She kept the whole place in a state of upheaval; matched his profanity with her own, or, this failing, had a fit and thus got the desired indulgence. Her father sent her to his sister's in the country. Here they failed utterly to control her; she slapped them and pulled their hair or fell in a fit if corrected, and even threatened suicide. Her father married and tried to care for her at home, but she wanted to rule everything and everybody, refused to work or dress properly, exposed herself and talked foolishly. She canvassed several streets in Boston, begging. She represented herself as an orphan child, eldest of six.

Committed to the Boston Society for the Care of Girls, November, 1911. In the first place her conduct improved in every way. Transferred, because she proved "too great a strain." Tried in two other families, she showed herself irresponsible, bad tempered, subject to fainting fits and feigned attacks of acute indigestion. Imagined herself the victim of hatred and persecution on the part of her father and stepmother. Wrote letters to newspapers to arouse public sympathy. When reasoned with or corrected, threatened suicide. It was felt that she might be mentally unbalanced; was examined and pronounced sane.

Committed to Lancaster, January, 1912. At first she showed signs of improvement; was obedient, neat in person and room, and worked well without supervision. After a few months all her old tendencies reasserted themselves. She was stubborn, incorrigible and disagreeable. In her violent fits of temper she once attacked an officer with a broom and another time bit an officer in the breast. She assumed a stiff shoulder. She was tried in several cottages, but her fits of insubordination became more and more frequent. In December she had a number of outbursts, when she kicked and screamed for hours. These outbreaks increased in violence, she swore, scratched, bit and spit at the officers, kicked out the panels of the door, and used the vilest language imaginable. After some of the attacks would seem penitent and at times would go several weeks without an outbreak.

May, 1913, attempted suicide by hanging. May 18, 1914, was much disappointed because she could not fulfill a desired whim. Cried during the night. Seemed all right the next morning. Without warning she attempted to drink household ammonia; her mouth was badly burnt. After this was quiet until the next day, May 20, when she began to talk irrationally. Tore the shades from the windows, tore her clothing, made a mess of her room generally. Screamed, cried and laughed alternately. Passed into a state of sexual excitement as shown by her talk and actions. Said she had on a gown of Irish point lace, the material of which had been brought over from Paris by a friend. That she had made money to pay for it during the past few days by prostitution. Did not seem to know where she was, the month, the day of the week or the time of the day. The next day was quiet, would not talk, did not appear to know those about her; had written obscene words on the window. Taken to the Westboro State Hospital for observation and treatment; on the way seemed to come to her senses, recognized and talked with the nurse who was with her. Physical examination negative.

A report from the above hospital, dated Dec. 4, 1914, states that: "She has continued to have frequent outbreaks when she is very much disturbed, and these outbreaks seem to come regardless of outside circumstances. She showed many mental symptoms suggestive of dementia precox, as, for instance, recently during a disturbed period she repeated certain phrases over and over again in a stereotyped manner."

They made the diagnosis of imbecility, with psychosis.

CASE 7. E. G. Irish. Born October, 1896. Father shiftless, alcoholic, insane. Mother alcoholic, sex offender. Two of mother's sisters alcoholic, sex offenders. Older brother has been in juvenile court and a younger brother in parental school. Home materially and morally bad. Hardly a week passes that the police are not called in.

E. worked in a store, was given a week's vacation on account of poor health, did not return. She arranged to go on the stage, but was prevented. She ran away from home repeatedly. Stayed for a time with an immoral woman; later went to a house of ill fame where she was found. She had had nothing to eat for several days. Her clothes were in a deplorable condition. She was found to have diseased lungs and was taken to a hospital. She was

placed in several families, in all of which she was very rebellious and discontented.

She was sent to a trade school, went one day but would not go back. Drank the contents of a bottle said to be poison; was taken to the Emergency Hospital where she was unconscious about four hours. She made several attempts to take her life while at the House of the Good Shepherd, and at their request was examined by an alienist and sent to a hospital for observation. She worked at the Carney Hospital as ward maid for a few days. She left without telling anyone and carried off the key to the ice chest. Was found, brought back, given another trial, but only remained a short time. She was taken to the Boston City Hospital for observation; reported to be normal.

Committed to Lancaster, August, 1912. An attractive, ladylike, well-appearing girl. Seemed much superior to most of our girls. In sixth grade of school. We had been warned that she threatened to kill herself if she came to Lancaster; precautions were taken to prevent this. The second day she scratched her arms in what she said was an attempt at suicide. A few days later she was found in her room with a wet towel tied tightly around her neck. Was reported black in the face and unconscious. All attempts to arouse her failed. She lay quiet in bed with eyes open, occasionally winking but apparently not seeing. There was no response to any outside manipulation. Would not swallow. As her condition remained unchanged for a considerable time she was sent to a state hospital. Observation failed to reveal any psychosis and she was returned to Lancaster.

She was placed in a family, but did not do well. Was arrested for being drunk and disorderly. The officers were frightened by her repeated attempts to take her own life and her irresponsible behavior. She was sent to the Psychopathic Hospital for observation and for the fourth time declared not insane. Sept. 10, 1913, was discharged by the trustees of the Lancaster School as an unfit subject. Returned to care of her guardian.

A report from the Psychopathic Hospital states that: "Probably her suicidal attempts are not due to a psychosis, but result from an emotional crisis. She is not insane. Psychological examination: Binet test, does the twelve and fifteen year old series. This is better than you would expect, because the most noticeable thing about her is her inability to learn from and profit by experience. She is suggestible, follows the path of least resistance.

"*Diagnosis.* Not feeble-minded, but subnormal. Within the border-line of defective delinquent."

CASE 8. F. D. American parentage. Born February, 1895. Father alcoholic. Mother migranous, sex offender. Three aunts tubercular. Mother's mother had a very violent temper. Sister a delicate looking girl, refined and of an irreproachable reputation. Environment very bad until five years old, after which she was boarded in good families. Was always untruthful, but gave no real trouble until she was thirteen years of age, when she became sly and deceitful. Had violent tantrums. Smoked, got into bad company. In house of ill fame five weeks.

Committed to Lancaster, March, 1910. A pretty,

attractive girl. Small, fair hair and complexion, blue eyes; face in repose has a look of refinement, at other times, hard, hardly human. Holds her head oddly. Has a peculiar gait, walks with one foot over the other, toes in. A sulky, headstrong, unmanageable, disreputable girl. Gloried in her former life and wished to return to it. A constant trouble maker among the girls, enticing them to evil. Had to be sent to the disciplinary cottage. Began to act like a maniac. She barricaded the door, screamed, pounded and raged. She fought and bit the attendants and had to be put in a straight jacket. She managed to get this off and tore down the shelf, which she threw out of the window. She threw a cup and a glass jar at an attendant who passed below her window. She kept this up for a week, swearing and using obscene language. We did not feel, in the face of our other experiences, that we could certify her as insane, and the authorities did not like to send her to the Reformatory for Women, but she became so violent that at last they were forced to do so. After her release from the Reformatory she ran away and could not be traced. Later we heard she had been found in a camp of Italian laborers and sent to the Bedford Reformatory, New York. The assistant at Bedford says she ran away from Boston at the time of a strike with one of the strikers, and later formed this camp with him. Here she acquired the drug habit, and seems to have been the common property of the camp. On her arrival at Bedford she used the same tactics as at Lancaster, immediately barricaded her door and broke everything possible. Everyone worked with her and for her, but she grew more unmanageable and finally, considering the case a hopeless one from their point of view, she was committed indefinitely to the Matteawan Institution for the Criminally Insane.

She was returned to Massachusetts and sent to the State Infirmary for observation. In response to a letter of inquiry, I got the following: "She was seen by alienists and considered non-committable. While in the insane ward she was quiet, indolent and lazy, but caused no special trouble. She very frequently had outbursts of temper. Used profane and obscene language as well as attempting violence. As far as I can ascertain she would seem to come more directly under the classification of moral or constitutional inferiority."

CASE 9. S. N. Colored, illegitimate. Born January 23, 1901. Was committed to Lancaster November, 1911, on complaint of principal of school. She did not do well in her studies, disturbed the school; a very bad influence on the boys and girls in her room. Would run away and frequent disreputable places of amusement, continually stole. She has shown immoral tendencies since she was three years old. December, 1911, passed the Binet test for ten and one-fifth years (was eleven years old). A small, undeveloped child, has a congenital cataract and weak arches. In the school she has been a very difficult child to manage. She has lived in four different cottages, in each of which she caused so much disturbance and was so insubordinate that a move was necessary. She is very unclean, even filthy; a constant bed wetter.

She has an extremely violent temper and invariably when corrected threatens to commit suicide.

Her language at such times is most profane and obscene. She will throw herself on the floor, kick and scream. On several occasions she has spit in the faces of officers. At one time she bit the neck of a girl who came to the assistance of the teacher she was attacking. When shut up in her room during one of these outbreaks she looks more like an animal than a human being. At times she crouches in a corner of the room, her small shining eyes following whoever may be in the room, as if ready to spring on them, her hair pushed up until it stands from her head in disorder, her expression demoniacal. During these times she will not answer questions. The room is in disorder. Everything that can be has been smashed and the litter strewn about; windows broken, hooks pulled from the walls, base boards smashed, her clothing torn, curtains, bedding, etc., in shreds. Again she will pound, scream, shout obscene sentences and make everyone within hearing uncomfortable. She usually has to be carried to her room. She will kick, scratch and bite while being undressed. Without provocation she will hide under beds, in dark closets, in the coal bin or the ash bin and refuse to come out. She will not comb her hair, brush her teeth or clean her room without strict and oftentimes strenuous supervision.

One report reads: "She is extremely disagreeable and insolent, in both manners and speech. Not a day passes but that she refuses to do things she is told to do, but when told not to do the same things she will immediately do them. Sometimes she will refuse to obey and will go and lie under a table or go into a closet. She is often reported from school for various misdemeanors. At times she refuses to answer to her own name and will only answer when called by her teacher's name. Whenever punished she will refuse food in any form for days."

Another report says: "She is mean and deceitful, is a continual tale bearer and so a constant trouble-maker among the girls. Her work is slack. Shows no interest or desire to learn to do better, is very untidy and dirty. Mentally—average, but slow. She usually has an outbreak just before the menstrual period; during the period she is more amenable than at any other time."

The superintendent writes: "She is very animal-like in all her habits and has shown absolutely no improvement since she came to the school, so that we feel it would be impossible to place her. On the other hand, she has a most demoralizing influence in the institution and we have accomplished absolutely nothing by way of reform in the three years she has been with us." I have never been able to satisfy myself that she has any false ideas. She can be made to behave for a short time by telling her that she will be sent to an insane hospital or that some surgical operation will be performed on her if she does not mend her ways.

Diagnosis. Defective delinquent of the explosive type.

There is no question in my mind but that in our work with mental defectives we have an irregular development to deal with. In many cases there is a defect of all the mental faculties; in others, many of the mental faculties are sufficiently developed to pass for normal, while other

faculties are defective or have never been developed. Many intelligent people find certain things much more difficult to master than others,—language, mathematics, music. Many masters of finance do not have the same idea of right and wrong as does the average person. How much more marked may the unequal development be in the unintelligent and the defective! We should not expect a child brought up in a family where promiscuous sexual indulgences are common, and where getting caught is the only crime connected with thieving, to have the same standards of morality as one differently situated. It is oftentimes difficult or impossible to determine whether we are dealing with a defect or whether the apparent defect is due to a lack of development, and if the latter, whether there is a possibility of developing the desired faculties.

The Binet and other psychological tests fail, I believe, to differentiate many of the high-grade defectives. The defect has, in some cases, to be determined by observations of some length. A carefully kept history of the transgressions is, I believe, important in determining whether a defective delinquent should be allowed to live in the community or not. Engrafted upon, or because of, the defect we often have a psychopathic condition.

The above cases differ one from another in many ways, but they have certain qualities in common:—

First, they are all delinquents. They have been judged and committed as such by the courts.

Second, they are only partially responsible for their acts, and have no relatives or friends who are able to control them.

Third, the hysterical symptoms, the exaggeration of symptoms due to physical defects and the simulations of disease oftentimes increase their inability to compete with other more fortunate individuals in earning a living.

CONCLUSIONS.

First, they are a prolific source for the spread of venereal diseases.

Second, their children will undoubtedly be as abnormal as the mothers, or more so.

Third, they do not belong in a reform school, as they cannot be reformed. They upset the discipline, and are a detriment to the best interests of others who can be helped.

Fourth, they do not, with one exception, belong in an insane hospital or a feeble-minded school. This, I believe, has been proved by the repeated terms of observation in insane hospitals and wards which the more questionable cases have been given.

Fifth, the expense of proper custodial care would be much less to the state than under the present unsatisfactory system when we consider the time taken by the courts, probation officers,

police, their intermittent control in more expensive state institutions, etc.

H. G. Wells, in his book entitled "Marriage," makes the leading character refer to what he calls a "Gawdsaker." When asked what a "Gawdsaker" is he says, "He's the person who gets excited by deliberate discussion and gets up wringing his hands and screaming, 'For Gawd's sake let's do something now!'" Without being a Gawdsaker, I believe the time has come when we should ask for custodial care of the more definite cases of the type given above, and if we decide on some definite plan and all work for the same plan, I believe we can get what we ask for.

NOTE.—Chapter 595, Acts of 1911, providing for the maintenance at the Reformatory for Women, the Massachusetts Reformatory and the State Farm of departments for defective delinquents, Section 12. "This act shall take effect when the departments named in Section 5 are ready for occupancy. The prison commissioner and the trustees of the State Farm shall notify the Governor when said departments are in a suitable condition to receive inmates; and the Governor may then issue his proclamation establishing such departments as places for the custody of defective delinquents."

SOMATIC CHARACTERISTICS OF GENERAL PARETICS.*

BY DONALD GREGG, M.D., BROOKLINE, MASS.,

Assistant Physician to Out-Patients, Boston Psychopathic Hospital.

INTRODUCTION.

STIMULATED by the articles and work of Dr. John Bryant, I have become interested in seeing if there is any relationship between individual types and certain kinds of mental disease. In brief, the thesis advanced by Dr. Bryant is that the human race stands midway between the carnivora and the herbivora; that certain individuals are pure carnivora, and others, pure herbivora, while the majority of mankind is of a mixed type; that pure carnivora, or pure herbivora, when unable to obtain or digest their appropriate diets, and for other reasons, are more likely to become afflicted with disease than are individuals of a mixed type, and that the kind of disease that attacks an individual depends upon the type to which he belongs—the carnivorous individual being prone to the diseases that afflict the carnivora, and the herbivorous individual being prone to the diseases that afflict the herbivora.

Races living in the tropics are generally herbivorous in type, whereas as one proceeds northward, the characteristics of the races become more and more carnivorous in type. Thus, a pure African negro is herbivorous, and the Anglo-Saxon often carnivorous. This variation

* Being Contributions from the Psychopathic Hospital, Number 67 (1915,4). The paper was read at the meeting of the Boston Society of the Medical Sciences, January 19, 1915. (*Bibliographical Note*.—The previous article, by Dr. John Bryant (1915,3), entitled "The Carnivorous and Herbivorous Types in Man," was published in the BOSTON MEDICAL AND SURGICAL JOURNAL, March 4, 1915.)

in type is believed to have come about as a result of diet,—an herbivorous diet being most easily had in the tropics, and a carnivorous diet in the north, where in winter vegetation is snow covered, and as a corollary to this theory, it may be added that in the tropics certain individuals flourish and certain other individuals go to pieces. It is to be expected that neurasthenia, debility, and brief success will attend a long, slim, high strung, difficult-sweating individual, and that relative success will remain with a thick-set, phlegmatic, vegetable eater upon migration to the tropics.

Bean divides the human race into the epitheliopath, or hyper-ontomorph, which corresponds to the carnivora, and the meso-epitheliopath, or meso-ontomorph, which corresponds to the herbivora. These two types differ distinctly in habits, anatomically, and in susceptibility to certain diseases. The carnivorous type is exemplified by the quick-thinking, quick-acting, high-strung, quick-eating individual, with slow pulse, low blood pressure, and sub-normal temperature. In appearance, this individual is of the long, lithe variety, with sallow complexion, long head, more prominent cheek bones, eyes near together, ears long, thin and flaring, nose long and thin, chin pointed, neck long, prominent Adam's apple, shoulders sloping, narrow costal angle, long waist, narrow hips, and long, slender extremities. On the other hand, the herbivorous type is exemplified by the more ponderous thinking, easy going, slow-eating individual, with higher pulse rate, blood pressure and temperature, and in appearance this second individual is of the shorter, heavier variety, with rosy complexion, round head and face, widely set eyes, ears thick, wide and flat, nose flat and wide, square chin, short, thick neck, square shoulders, wide costal angle, barrel chest, short waist, broad hips, wide, straight back, and shorter, heavier extremities.

In general medicine we have recognized clinically, the tendency of certain diseases to afflict certain types of individuals. We have distinguished the quickly fatal type of diabetes attacking the young, thin man, and the relatively innocuous diabetes of the old and fat. We have recognized the thin Anglo-Saxon servant girl as the commonest soil for the symptoms of hyperacidity and gastric ulcer. Pediatricians have recognized the highly strung, fine-lined type of child, prone to carbohydrate intoxication, as shown by carmen lips, acetone odor of breath, and gastro-intestinal symptoms. We have recognized a tubercular type of individual; also the fat woman inclined to gall stones; the full-blooded, thick-set, aldermanic type inclined to interstitial nephritis and the short necked, thick-set individual, who is given a poor prognosis when afflicted with pneumonia; the individual inclined to chronic appendicitis, and those prone to the acute fulminating appendiceal attacks, and the long drooping, neurasthenic type with ptosis

and faulty carriage. Only recently have investigators suggested reasons for these differences in the proneness of different types of individuals to different classes of diseases, namely: that the herbivorous individual can be expected to suffer from diseases involving mesodermal structures, that is, the gall bladder, kidneys, and arteries; while the carnivorous are prone to diseases of ectodermal structures, that is, the lungs, gastro-intestinal tract, and nervous system.

From the point of view of the general practitioner, fascinating lines for investigation stretch forward in the field of diagnosis, prognosis, and preventive medicine when one considers this hypothesis concerning mankind. Given an early case of appendicitis, should prompt operation be indicated because the individual is of the type that will probably soon develop general peritonitis? Or given a case of pneumonia, should digitalis be started early because cardiac involvement is likely to occur in that type of individual? Or given a child of carnivorous stock, how far can diet swing that child away from the pure carnivorous type, prone to disease, to the mixed type, relatively immune? And so on, in fascinating ramifications.

From the point of view of the psychiatrist, it has occurred to me that a study of the relationship between individual types and mental disease would be of interest, if such a relationship could be found.

Method. Although the records of the Psychopathic Hospital have not been compiled with an idea of showing clearly whether an individual patient belongs to the herbivorous or the carnivorous group, yet from the record of the height, weight, temperature, pulse, respiration, and the general physical examination, certain general conclusions can be drawn. One hundred cases of general paresis were chosen for study. Cases of this disease were picked for two reasons. In the first place, the diagnosis of general paresis is now based, not upon indefinite clinical evidence, but upon laboratory findings, that is, evidence of syphilitic involvement of the nervous system, as indicated by a positive Wassermann reaction in the spinal fluid; and secondly, because this disease occurs mostly in mature adults who have reached their full stature and development before falling victims to the infection, and are consequently likely to show by their physical development the type to which they belong. Of the one hundred cases studied, 81% showed positive Wassermann reactions in the spinal fluid. In the remaining 19 cases, positive Wassermann reactions were obtained from the blood, and the spinal fluid was either suggestive or else not examined. Thus, in all cases, there was positive evidence of syphilis.

Of the one hundred cases chosen, all were males. The civil status was as follows:

Single	26
Married	65

Widowed	4
Unknown	5

In age, they varied from 18 to 62 years, and were distributed by decades as follows:—

Second decade	1
Third "	5
Fourth "	44
Fifth "	34
Sixth "	15
Seventh "	1
<hr/>	
Total	100

The occupations were of many sorts, among them the following (that by lead or alcohol poisoning may have helped to undermine the nervous system): Three painters, one steam fitter, one rubber worker, two liquor dealers. Inasmuch as Dr. P. C. Knapp has already written of the menace to the community of general paresis in certain occupations, it is also interesting to note among these one hundred cases, one automobile worker, one motorman, one brakeman, one locomotive engineer, one Pullman conductor, one railway conductor, one car inspector, one janitor, one captain of a tow-boat, one lighthouse-keeper.

The nationalities represented were as follows:

Irish	30
English and Scotch	10
Swedish	3
Russian	5
Belgian	1
Canadian	8
United States	26
<hr/>	
83	
United States, colored	5
Italian	3

Total	100

In other words, 83 were representatives of Northern races, including Anglo-Saxon, Slavs, etc., and only 17 representatives of Southern races.

From insurance tables of the United States and Canada the normal height and weight of individuals at various ages were obtained. These tables showed the average heights of males to be 5 feet 7 inches. Among the hundred cases studied, the average height was 5 feet 8 inches. Sixty-eight per cent. of the cases were of average (*i.e.*, 5 feet seven inches) or more than average height, while only 32% of the cases were subnormal in height. A study of the weight showed that 84% were subnormal in weight for their height and age. These cases averaged 23.1 pounds subnormal in weight. Eleven per cent.

of the cases were above normal in weight averaging 11.4 pounds above normal.

Discussion. The study of these one hundred cases was undertaken to verify if possible, from the incomplete data at hand, the hypothesis that the discrepancy between the large number of individuals infected with syphilis, and the small number—about 3 or 4%, that develop general paresis, may possibly be due to the fact that only a certain type of individual is liable to develop nerve lesions, and that this type is the so-called carnivorous type. De Fursac, in his Manual of Psychiatry, states: "It is certain that syphilis is common, and that general paresis is rare, among Arabs, Abyssinians, and South Africans, as was shown by Ballet, but this proves nothing at all. It is quite possible that syphilis cannot produce the lesions of chronic meningo-encephalitis except in certain conditions created by civilization and absent among primitive and low races. General paresis is not, as was once believed, the special privilege of cultured men. It affects the working classes as well as the upper classes. Why do only three or four per cent. of all cases of syphilis develop general paresis, while the rest escape it? Neither virulence of infection, nor neglect of treatment seems to be responsible for the development of general paresis, for many cases of syphilis remaining for years untreated, and characterized by extensive and destructive syphilitic lesions, never develop general paresis, while other cases of slight infection, promptly and vigorously treated, later, nevertheless, develop the disease. It would seem then that we are dealing here, not with a specially severe, or modified infection, but with a special reaction to it." Dr. C. J. White reported last summer that an analysis of 1016 cases at the Massachusetts General Hospital showed that only eight developed tabes and only one general paresis, and that 94% of the paretics came from Great Britain, or were descendants of the recent emigrants from the British Isles. Also, that of 178 paretics, only a fraction more than 1% had ever suffered from late cutaneous syphilis. Can it not be thought that instead of a special type of infection, there is a type of individual particularly susceptible because of his physical characteristics to develop syphilis of the nervous system?

CONCLUSIONS.

First. There is considerable evidence to show that individuals of the so-called carnivorous type are particularly susceptible to diseases of the nervous system.

Second. In a study of 100 cases, diagnosed clinically as general paresis, among whom 81 showed a positive Wassermann reaction in the spinal fluid, and the remaining 19 a positive Wassermann reaction of the blood, while the spinal fluid was suggestive or untested, the hypothesis that these cases were of the carnivorous type was supported by the fact that 83% of them were Northern races; 68% normal or above

normal in height, and 82% averaged 23.1 pounds subnormal in weight.

Third. The hitherto unexplained discrepancy between the many cases of syphilitic infection and the small per cent. of syphilitic individuals developing general paresis, may be explained, not on the hypothesis that there are varying strains of spirochetes, or by coincident environmental strains, alcohol or other intoxicants, but by the fact that only a certain type of individual is susceptible to syphilis of the nervous system.

Reports of Societies

THE BOSTON SURGICAL SOCIETY.

PROCEEDINGS OF THE BOSTON SURGICAL SOCIETY.
STATED MEETING OF FEBRUARY 1, 1915,
BOSTON MEDICAL LIBRARY.

The President, DR. GEORGE H. MONKS, in the chair.

A REPORT ON SOME CASES OF PERINEAL PROSTATECTOMY.

Dr. Franklin G. Balch read a paper with this title, for which see page 507.

DR. A. L. CHUTE: Some of the writer's points I agree with, others I am unfamiliar with, still others I disagree with, in spite of the fact that one feels a certain amount of timidity in disagreeing with a method that has given such good results as has his.

In the first place, I agree most heartily with the writer regarding the value of the perineal route in prostatectomy. I believe it has been too little used of late. I do not, however, esteem it as highly as the writer, since I use it on only about one-third of my cases. I feel that I can do the others better by the suprapubic route. I do, however, contend that the perineal operation is the only one that is universally applicable in cases of prostatic obstruction. By its use one can remove the big prostate, the small one, the malignant type, as well as the fibrous bar at the bladder outlet; in fact all the types of prostatic change that produce obstruction, including the so-called third lobes. As Dr. Balch has shown, one can also remove calculi by this route.

I think no one contends that the suprapubic operation can be done with as little mortality as the perineal. It is easier, and while it has a larger mortality, especially in the hands of the occasional operator, it requires little skill, and the final results are usually good. Therefore it is largely used and will continue to be. But the above are not the only reasons why the suprapubic operation is the favorite. The perineal operation has been followed by a goodly number of cases of incontinence, by perineal fistulae, by injuries to the rectum, by failures to remove the obstructing mass, misfortunes which I believe are rarely encountered by the operator skilled in the perineal route, but common in the hands of the occasional operator. These complications practically cannot occur following the

suprapubic operation, which, though it may kill, almost never maims.

Dr. Balch has modified the usual technic of the perineal operation so that it sounds easy. However, I have to confess that I have never carried it out according to his method, nor even seen it done; but his incision of the membranous urethra without attempting to uncover the whole perineal face of the prostate, sounds attractive and has certainly made the operation much easier and quicker and done away very largely with the danger of injury to the rectum. His method of enucleation seems reasonable. It is the principle generally used when the operation is done from above, and simply varies in that it is carried out from below. That he is very expert in the management of his drainage is indicated by the fact that he does not have perineal urinary fistulae, that restoration of function comes early, that his patients have perfect control, that epididymitis is uncommon, and the patients' stay in the hospital is short.

There are certain things that Dr. Balch advocates that I disagree with, and constant irrigation is one of them. I do not fear it much on the score that a patient may bleed more than you think without your recognizing it, though I think this is possible. My chief objection lies in the fact that constant irrigation does not allow one to estimate carefully the amount of work done by the kidneys as represented by the secretion of urine. I believe that the great danger following prostatic operation is renal insufficiency. Although the use of spinal anesthesia and knowledge of the renal function diminishes the probability of this, it does not wholly do away with it. It is, therefore, most important to know as accurately as possible the amount of work the kidneys are doing. This is impossible during the time irrigation is kept up. While I think Dr. Balch's incision into the membranous urethra and his method of enucleation are most desirable for most of the cases, especially the ones with the large, adenofibromatous prostates, yet I believe it would be inferior to the transverse incision of the perineum with full exposure of the gland in cases of cancer and fibrous atrophic prostates. It is my belief that these cannot be enucleated and must be dug out piece-meal with rongeurs or scissors. In order to do this, it is absolutely essential that one have a good exposure of the field. I should feel that his enucleation from below would have even greater limitations than the enucleation from above, which I find very unsatisfactory in these two classes of cases.

I wish to congratulate Dr. Balch on the results achieved in this series of cases. While he lost two cases in twenty-eight, one died of a perforation of the sigmoid by a rectal tube, giving mortality which was actually due to the prostatectomy as but 3 1/2%—a very low one indeed.

His absence of fistulae and incontinence in these cases is very gratifying, but the thing that arouses my envy especially is the small number of cases of epididymitis that he has. A very large percentage of my cases, whether I do them perineally or suprapubically, present this complication. I suppose his freedom from it is due in a measure to the very short time that his patients have any tube in the urethra and to the very little instrumentation that they receive.

DR. PAUL THORNDIKE: I propose not to take more than five minutes, for methods of operation

have been discussed already very thoroughly all over the country. Dr. Balch has used a method of approach which is quick. Dr. Young's method in my hands takes much longer. Dr. Balch's operation is a distinct advance toward the better way, a quick way. At the City Hospital, where we get the old and feeble cases, I have to do the operation in the shortest possible time. We have to take the worst cases and do the best we can with them. There are distinctly inoperable patients, upon whom the surgeon would rather not operate, but must do so. They are the worst kind of prostatics, with bad arteries and bad hearts, all to be subjected to operation, because there is nothing else to be done to make them comfortable. By this suprapubic method I can operate quickly, easily and thoroughly, and either with spinal or local anesthesia, without much effect upon the kidney. I did a lot of them last year—no deaths, no leaks, one case of hemorrhage ten minutes after operation, which was packed and ceased quickly. I believe the whole key-note of success in these feeble old cases is quickness. In a young case a good result can be obtained, no matter how one does it. In an old and feeble case the operation must be done quickly. Quickness, facility, the least anesthesia and least fussiness in the after-care are the essentials. In the after-care there is nothing necessary except to nurse the patient. If you keep disturbing the patient with washings and dressings you are inviting trouble. I never wash out the bladder unless it is dirty. My routine is "the simplest, quickest and easiest way both in operation and after-care."

DR. HUGH CABOT: I want to avoid entirely the question of route because I am frankly in doubt about it. It depends, perhaps, upon how long one's finger is; I have rather a short finger, and unless I can borrow length from Dr. Balch I cannot expect to do what he can. I want particularly to discuss the kidney function, and anesthesia. Lowness of kidney function does not seem to me a contraindication. I believe that stability is far more important and whether there is retained nitrogen of the blood. That is the final test. If the nitrogen of the blood is not above normal limit we have a good operative risk. We may have a renal function of 30 and yet a high nitrogen, and an extremely hazardous risk. I believe in stability rather than highness or lowness of function. Also, simply one test of function is not enough as function may fall after admission. Acute pyelonephritis has this effect and may practically abolish the kidney function.

Our views in regard to spinal anesthesia have undergone considerable change. Up to about a year ago, we were inclined to regard it as the anesthetic of election in bad cases, but have largely abandoned it for this purpose, owing to the enormous drops of blood pressure, which were very common and which we came to believe were in some way associated with arteriosclerosis. Not only did these patients with diseased blood vessels have a greater drop of blood pressure, which sometimes amounted to 100 mm. of mercury, but they seemed less able to recover their blood pressure, and therefore more likely to suffer from cardiac weakness after operation. In younger patients without arterio-sclerosis these enormous drops have not seemed to us to occur, and we still use it freely under those circumstances. For the older patients we now use gas and oxygen. Ether we have entirely discarded because we believe it to be highly objectionable in the conditions of

pulmonary irritability with more or less definite disease which is so common in these patients. With the gas and oxygen we combine Crile's method of anoci-association.

DR. LINCOLN DAVIS: I should like to mention one point that was brought to my attention in Rochester. The operator was taking great time and care in stopping hemorrhage. He was doing a suprapubic operation and was suturing the neck of the bladder. He said, "We used to think we had to be in a great hurry to do this operation. We are trying now to stop the hemorrhage absolutely. We are doing this rather than a rapid operation." It seems to me that this is an important point. How often a rapid operation is followed by a prolonged steady oozing from the wound. It is the post-operative loss of blood which starts the patient on the down grade and makes him an easy prey to pneumonia or other complications. I believe hemorrhage is the great factor in the mortality of prostatectomy, and that the prevention of hemorrhage is of far more importance than the saving of a little operative time.

DR. BOTTOMLEY: I want to ask Dr. Balch why he thinks enucleation from below causes less hemorrhage than enucleation suprapubically.

DR. BALCH: I don't know why, but in my cases it seems to do so. You can also control it more easily by packing from below.

ON THE FIXATION OF FRACTURED BONES IN INFANTS AND YOUNG CHILDREN.

DR. E. H. BRADFORD and DR. ROBERT SOUTTER presented a paper with this title, for which see page 508.

DR. F. B. LUND: I have never treated a fracture of the thigh in an infant. I think Dr. Bradford's scheme is a very ingenious one. It seems to me that I should find some difficulty in driving the hole accurately without taking away the soft parts. If I had a case, I should send it to him for treatment.

In 1911 I read before the Massachusetts Medical Society a paper entitled, "Experiences of a Beginner in the Operative Treatment of Fractures," in which I reported eleven cases, four of which were fractures of the femur. Since that date, I have operated upon 29 cases of fracture of the femur and about 100 cases of fracture in general, 18 by Lane plates and 9 by the Parham and Martin band.

All of my earlier cases were patients in whom conservative treatment had failed, and either non-union or mal-position, or both, made the operation necessary. These operations in the old cases were difficult; there were many adhesions to the muscles, nerves, and vessels, old callus had to be cleared away, and in some of my early cases the re-position of the ends was not perfect. Two of the four cases reported in the former paper were failures; either on account of imperfect fixation by splints or imperfect external fixation, the fragments came apart, and although they finally united, the plating operation had done no good.

Remembering these cases and the large number of delayed unions, non-unions, and cases of deformities that I had seen in conservative treatment of fracture of the femur, I have continued to practise operative fixation in about half of the cases of fracture of the femur, namely: transverse fractures (which require plating), all fractures of the upper third which cannot be brought into good apposition

by conservative methods, fractures close to the knee, with overlapping of the fragments, which rarely can be reduced by non-operative measures, oblique fractures of the shaft which cannot be brought into position by extension and fixation in plaster of Paris.

I have learned a few things in regard to plating: In the first place, that while we ought to use as small a foreign body as possible, a long, heavy plate is better than a small, weak plate for a fracture of the femur.

Bone plating is, I believe, the best method of fixation for transverse fractures. The screws for bone plating should have wide, deep threads like wood screws. The Sherman screws, which have very shallow threads close together, do not hold as well in bone. The ends of the Sherman screws, which are flat with a thread cutting arrangement, are so large that if you bore a hole big enough to let them in, the base of the screw next the head does not hold, and the screws are apt to loosen.

For the last two years, I have had no infections. We have used a two- or three-days' skin preparation, and I believe that most infections come from imperfect preparation of the skin. I believe it very important to keep the fingers out of the wound as much as possible because gloves are apt to become torn on jagged ends of bone.

The suture of the fascia lata prevents muscle hernia, and stops hemorrhage by compression of the muscle against the bone.

After operation, fixation with plaster of Paris.

In oblique fractures and in comminuted fractures, the Parham and Martin band has distinct advantages over plates. It is mechanically more perfect. A band bound tightly around the bone forces the oblique surfaces into apposition so they cannot slip by, and if they should slip a little, it would tighten the band rather than loosen it. The pull of the muscles coöperates with the band itself to hold the band tight. It is easier to put on than the plate, requiring no driving and no care about screws. Dr. Cotton has alluded to the manner in which the extensive oblique surfaces unite when held in contact.

By the way, in plating one should always use a hand screw driver instead of one driven by a spring, because one wants to feel that the screw is of the right tightness,—not too tight or too loose.

Plating is more satisfactory in the middle of the shaft of bones than at the ends, because the thread does not hold in the cancellous tissue, and the cortex of the bone near the ends is too thin to hold the plate firmly. This is illustrated in some of the pictures that I shall show.

Fractures of the femur in children usually do well by vertical extension, but the operative treatment of fractures has as definite success even in children as it has in adults. Children are so hard to keep still, and the constant care and readjustment of extension apparatus is very trying. After plating or banding in adults or children, the patients can be put up in comfortable plaster of Paris bandages, where they can be kept for three weeks, merely cutting a window on the tenth day to take out the skin sutures, which is a distinct advantage.

As to results; I have spoken of two failures in my early cases. In early cases also, there were two infections. The first case was a patient with fracture of the upper end of the shaft, with marked deformity, who refused operation. The ends were in perfect apposition, but the first time he got out of

bed he fell down and broke his femur. The displacement was so marked that he saw himself that something would have to be done. A heavy Lane plate was applied. It was a long and difficult operation. A fourth-day infection appeared. The wound was opened and washed out daily, and the plate was left in position for six weeks, and then removed, and he has a perfect result.

The second infection occurred in a case of comminuted fracture in the lower third of the shaft in an alcoholic of about 60 years of age,—a very poor operative risk. After plating with a moderate-sized plate, he became delirious and fouled his dressing so that the wound became infected. A large sequestrum had to be removed, together with the plate, and the remaining jagged fragments overlapped so that a week or two later, one of them eroded the femoral artery and the patient died of hemorrhage.

My other fatal case has been described by Dr. Bruce. It was a difficult operation for an old fracture of the upper end of the femur performed under nitrous oxide and oxygen anesthesia. The patient was put to bed in excellent condition, but died suddenly of embolism.

I have had three cases only in which the plate had to be removed. Only one of these apparently was infected,—the case described above. In one case, the plate broke and union did not take place. Afterwards Dr. Cotton replated the leg successfully.

I have had three cases of comminuted fracture. One case of spiral fracture of the upper end of the femur with very bad deformity caused by a gunshot wound was treated by a long 8-screw plate and two wires, with excellent result. This case was published in the *Journal of the American Medical Association* of Feb. 21, 1914. One comminuted fracture was treated by a band, and one by a double band. I have x-rays of these cases to show.

One case in which bone plating was attempted but not performed is of interest. The patient was a farmer from New Hampshire, who had a shortening some two months after the injury, gangrene of the big toe, a large bed sore on the heel, and a large hematoma on the inner side of the thigh, over which could be felt running an artery. I felt that amputation was his best chance, but two of my colleagues advised me to reduce and fix the fracture with a plate. On exposing the bone and working around it, we opened the hematoma, and a large amount of dark blood escaped. A rapid hemorrhage began, evidently from the femoral vein, the patient fell into deep shock, and his life was saved only by a quick amputation.

I feel sure that my results in operative cases have been better than they average by conservative treatment, but I have no statistics to prove it. The band cases, where wide and broad oblique fractured surfaces are brought into position, certainly unite more quickly than the transverse fractures, which have to be plated. I will show you a case of banding an oblique fracture of the femur in a case of ankylosis of the hip, with perfect union in six weeks. This case would have been very difficult to treat by extension owing to the hip ankylosis. A woman of 60 years of age had excellent union in three weeks, of which I will show a lantern slide; in this case also the lower end of the upper fragment almost projected through the skin directly under the patella,—surely a case in which conservative treatment would have been very slow and given very doubtful results. I now believe that the majority of cases of transverse

fractures of the femur ought to be operated upon. Fractures of the upper and lower third of the shaft, whether transverse or oblique, should usually be operated upon; and I also believe that in oblique fractures banding with the Parham and Martin bands is better than plating.

During this time, I have used the plates and bands in operating on both bones of the forearm, tibia and humerus, with most satisfactory results, and only one infection. I think there have been 100 cases in all.

DR. CHARLES L. SCUDDER: I want to present three new instruments which may be of interest in connection with the technic of the operative treatment of fractures.

You are all familiar, I believe, with the Lowman clamp, which is intended to grasp the two fragments of the fracture and to hold the steel plate in position while the drill is used and while the screws are placed. I have found the Lowman clamp inefficient in one particular—the third anterior and movable arm of the clamp does not always fit the bone and hold the plate accurately. I have, therefore, had this third arm so altered that it is adjustable. The efficiency of the Lowman clamp is thus, I believe, increased.

The second instrument that I wish to present is a bone lever. This consists of a flat, straight piece of steel to be used in bringing the over-lapping fragments together by leverage. The end of the lever introduced between the bones is rough on one side and smooth on the other. The rough side prevents the bone from slipping off the lever, and the smooth side allows the lever to be removed from between the bones more readily than if both sides were rough. The lever is grooved so that the bones may be easily approximated by pressure if the lateral displacement is great. I find this lever made in two sizes very helpful in replacing bones of the forearm and in fractures of the tibia.

The third instrument which I wish to present is a hook which is patterned after the Lambotte hook. This hook is made in three sizes. The hook is employed to draw the fragment of bone toward the operator and toward the wound through which the operation is being done. It is also used to steady the fragments upon which any operative work is being done. Smaller hooks are applicable to operations upon the ulna and radius, and the larger hooks for operations upon the tibia and femur.

These instruments are the outgrowth of certain necessities that have arisen in connection with the operative treatment of fracture cases. I believe that it is important for the surgeon to have all the necessary instruments that facilitate the various steps of any operative procedure. These three instruments, therefore, have been presented to the Society because they have been found helpful in the operative treatment of fractures.

THE COLLEGE OF PHYSICIANS OF PHILADELPHIA.

MEETING OF WEDNESDAY, JANUARY 6, 1915, AT 8 P. M.

DR. RICHARD H. HART, in the chair.

GASTRIC ULCER.

DR. JOHN B. DEEVER: The experience of the last few years of activity in gastric surgery has shown

both brilliant successes and dismal failures. It has been shown that no one operation will fit all cases, that variations in situation, chronicity and complications demand different methods of treatment until finally, by the slow evolution of clinical experience and observation, we are in a position to draw some conclusions regarding principles which should underlie the surgical treatment of gastric ulcer.

I believe the appendix is responsible for liberating the infection which in turn causes gastric as well as duodenal ulcer and other forms of upper abdominal disease in an overwhelming majority of instances. In my clinics at the German Hospital I have observed the almost constant association of chronic appendicitis and gall bladder diseases with duodenal and gastric ulcer. The focus of infection need not necessarily be the abdomen, though here apparently the association is more marked. That infection from the mouth may be the exciting cause of gastric ulcer is true perhaps in a small percentage of cases. The common association of chronic diseases of the appendix with gastric and duodenal ulceration is significant of a causal relation between the two through toxic products liberated from the appendix. We are equally concerned with factors preventing the healing of the ulcer, among which may be mentioned, the condition of the general health, the continuance of exciting causes in the muscular activity of the stomach, the action of the gastric juice upon eroded surface and infection implanted upon the bed of the ulcer. There is abundant evidence of a strong natural tendency to the healing of simple gastric ulcers in the human. Well directed medical treatment will succeed in healing most acute ulcers and a fair percentage of those on their way to chronicity, and in the absence of severe complications medical treatment should be given a fair trial before resort to surgery. Medical treatment in the chronic type of gastric ulcer must be radical, demanding from four to eight weeks' rest in bed and most careful feeding, for in the quiescent stage many a patient has been placed asleep in the eternal rest of the grave. We must not forget the marked tendency of cancer to develop on a chronic ulcer base, and all such cases are to be rated as the most disastrous medical failures. The clinical indications for operation are cases complicated by perforation, recurrent hemorrhage causing material drain upon health and persistent indigestion which does not yield to a fair trial of medical treatment. By this I do not mean indefinite temporizing. There is a difference of opinion concerning the correct surgical procedure in perforation. It is my belief that a primary gastroenterostomy is far more likely to be followed by immediate recovery, and certainly, the prospects of future relief are much improved. The mortality of those combining gastroenterostomy with closure of the ulcer is superior to that of those practicing only closure. I have reported 30 cases of acute perforation of gastric and duodenal ulcer in which gastroenterostomy was done as a primary procedure with one death. Since then I have had an additional case with recovery. In the presence of hemorrhage the time of operation is a question of nice surgical judgment, and I have regretted my decision in both directions and can advise only in the most general terms. Since it is too hazardous to wait for the re-formation of blood,—as that is a matter of days and weeks, it seems wise to wait only for the subsidence of shock, the refilling of the blood vessels by the body fluids

and by water administered and the restoration of the blood pressure to approximately normal level. Direct transfusion of blood will occasionally have a field here. The question of the proper surgical treatment of a gastric ulcer can be decided only after the abdomen has been opened and thoroughly explored. This often means that the stomach must be opened widely. While complete excision of the ulcer may be regarded as ideal, it can seldom be accomplished. Localized saddle ulcer on the lesser curvature, ulcers strictly limited to the pylorus or small punched out ulcers elsewhere in the wall are best adapted to excision. The so-called exclusion method should be ideal in bleeding ulcers, but in many situations it is impossible of application. Ulcers high up in the fundus of the stomach may be best treated in an indirect manner by jejunostomy. A most important point to be noted is that the patient with gastric ulcer belongs exclusively to neither the physician nor the surgeon. A common cause of failure is the lack of careful supervision of the patient by the physician subsequent to operation. In his half-starved condition the patient if not restrained will go to extremes in eating. In view of the fact that prevention is better than cure and that cure is difficult and perhaps impossible, I would urge that in all digestive disorders diligent search be made for evidences of chronic disease of the appendix and treat it to a drum-head court martial at the first sign of insubordination.

DISCUSSION.

DR. JOHN H. GIBBON: I have operated upon 20 cases of perforation with a mortality much higher than that of Dr. Deaver and much nearer that usually accorded this operation. I have, however lost only one patient operated upon within the first twenty-four hours following operation. From what Dr. Deaver has said I judge that his cases were mostly, if not entirely, early ones. I think some of these perforations are overlooked and the cases looked upon as cases of general peritonitis and are not operated upon because of the advanced stage. I cannot agree with Dr. Deaver upon the value of the x-rays, and would place my reliance in diagnosis upon (1) history; (2) x-ray study, especially with the fluoroscope; (3) gastric analysis. W. J. Mayo places the x-ray study first, history second, and gastric analysis third. Dr. Deaver and I disagree concerning gastroenterostomy in the presence of perforation. I should, however, do the operation in cases in which there is marked obstruction of the pylorus from the infolding of the ulcer and in which it is possible to operate early. There is certainly no objection to doing the ideal operation, except in cases in which much time has elapsed between the time of perforation and that of the operation.

DR. JOHN B. ROBERTS: The point made by Dr. Deaver concerning the etiology of gastric and duodenal ulcers has interested me very much. My attention was called to this matter years ago because I lost a patient upon whom I had done suprapubic cystotomy for stone, with sudden collapse ten days after operation. Autopsy showed a large perforated gastric ulcer, of which I had no knowledge and which came, probably, as the result of the cystotomy. A few years ago I had a case of ulcer in the duodenum following traumatic rupture of the bladder. In looking up the subject I was surprised at the large number of cases on record. There were at least a dozen cases of ulcer of the stomach and duodenum the result either of disease of the abdomen

or of operative attacks upon the abdomen. I think Dr. Deaver is right in respect to the probable causative relation between suppurative disease of the appendix, or of the gall bladder, and these gastroduodenal ulcers. His paper is to my mind a very important contribution to what I would call clinical pathology.

DR. JAMES TYSON: In my experience the diagnosis of gastric ulcer when not checked off either by operation or autopsy has not been very satisfactory. On the other hand ulcers are sometimes found in the stomach at autopsy when no symptoms have been present before death. Only a few of the digestive symptoms have a distinctive value. Perhaps the most valuable one is copious hemorrhage. The presence of a palpable tumor is good evidence of gastric cancer, but the possibility of mistake is illustrated in the case of a man who came to me several years ago with history of recurring hemorrhage and evident tumor in the right hypochondrium in whose case autopsy showed gastric ulcer.

DR. WILLIAM E. HUGHES: Dr. Jopson has reminded me of an exceedingly interesting case of duodenal or gastric ulcer in which the only symptom was profuse hemorrhage. The man died during operation as the result of a very peculiar hernia through the diaphragm because of which practically all of the abdominal contents were in the chest. A point of diagnostic interest to me is that almost all cases of perforating ulcer of duodenum and stomach that I have seen have had free gas in the peritoneal cavity within a few hours of perforation.

DR. JOHN H. JOPSON: The patient mentioned by Dr. Hughes and which he referred to me had been seen by him in consultation with the physician, Dr. Ellis, and an immediate operation advised. The patient was in good condition but took the anesthetic badly. He became cyanotic and there was persistent rigidity of the abdominal muscles. When the abdomen was opened the stomach was found enormously distended and there was a hard, circumscribed and stenosing ulcer of the first portion of the duodenum. It was proposed to do nothing but gastro-enterostomy. The small intestine was not found in its usual site; the cecum and appendix were found high up under the mesocolon near the median line just below the stomach. Examination of the peritoneal cavity showed an entire absence of the jejunum and ileum, excepting the terminal portion of the latter, which could be traced for a few inches from the ileocecal valve when it blended with the posterior peritoneum. I thought of thoracic hernia and passed my hand above the stomach and liver and around the diaphragm on both sides, but felt no opening. I then opened the lesser peritoneal cavity through the transverse meso-colon and passed my hand into it, behind the stomach. This was followed by a profuse hemorrhage, both from the retro-colic vessels and from the perforation which this slight manipulation opened up in the posterior wall of the ulcer. From this opening a large amount of dark, liquid blood and solid food particles kept pouring out in a flood which could not be controlled in spite of repeated attempts at suturing, and the patient succumbed. After lifting the stomach from the abdomen we found a hernia of the entire small intestine, excepting its beginning and termination, through an opening in the left side of the diaphragm, posterior to the stomach, into the thoracic cavity. Some of the coils of the intestines were adherent so that they could not be pulled down into the abdomen. The condition was evi-

ently congenital as the edges of the opening were thick and rounded, and, in combination with the obstructing bleeding perforating ulcer, rendered the patient's condition incurable.

Dr. JOHN B. ROBERTS: In connection with the case mentioned by Dr. Jopson I might say that I saw at the Mayo Clinic a case of congenital thoracic hernia. Dr. W. J. Mayo operated upon a young man for curious vomiting attacks. To his surprise and the astonishment of all of us he found that the stomach was up in the left chest.

Dr. DEEVER, closing: I cannot agree with Dr. Gibbon that seeing these cases early explains the low mortality; while some of my cases were operated upon within 24 hours, in one the operation was as late as thirty-six hours. The chief object of gastroenterostomy is to get these patients well promptly; and, secondarily, to keep them well. I would urge the cross-roads surgeon not to do gastroenterostomy; the small country hospital has not the best equipment for the procedure. I am not a strong advocate of the x-ray in diagnosis of these cases, but would prefer to open them up. When the ulcer has brought about a pyloric stenosis, of course, you can make a diagnosis; but then, according to Mayo, it is too late,—90% plus of gastric ulcer undergoing carcinomatous change. Dr. Gibbon and I do not always agree, but we seem to agree tonight upon the etiology. Dr. Tyson rather hit the bull's eye when he said that, exclusive of the post-mortem slab at the operating table, he thought the diagnosis of gastric ulcer was not satisfactory. The case mentioned by Dr. Hughes and Dr. Jopson is very interesting; had the man had his abdomen opened up a few years before they would not have had this pathology to report.

Book Reviews.

Psychanalysis: Its Theories and Practical Application. By A. A. BRILL, Ph. B., M.D., Chief of Clinic of Psychiatry, and Clinical Assistant in Neurology, Columbia University Medical School; Chief of the Neurological Department of the Bronx Hospital and Dispensary. Second edition. Philadelphia and London: W. B. Saunders Company. 1914.

This book gives in fairly brief form about as good an idea of the theories of Freud in regard to the nature and mode of origin of the psychoneuroses as is to be found in English. It also takes up the more recent extension of the Freudian theories to the psychology of wit and everyday life. Whether or not one can accept all these views, the knowledge of them is of great importance to every physician desiring to understand recent literature on the psychoneuroses. This second edition adds new material upon artificial dreams, the unconscious factors in neuroses, collecting manias, pathologic homosexuality, and fairy tales as a determinant of dreams and neurotic symptoms.

A Text-Book of Diseases of the Nose and Throat. By D. BRADEN KYLE, A.M., M.D., Professor of Laryngology and Rhinology, Jefferson Medical College, Philadelphia. Fifth edition. Thoroughly revised and enlarged. Octavo of 856 pages with 272 illustrations. Philadelphia and London: W. B. Saunders Company. 1914.

This has for fifteen years been one of the standard American text-books of the diseases of the nose and throat. It has grown with successive editions from 650 to 850 pages. It is somewhat large and complex for the medical student, but a useful and reliable book of reference for the specialist and general practitioner. The author is a pathologist and teacher, as well as a practitioner of large experience. He maintains a systematic survey of all contributions to the subject in the medical press, but uses only such as appeal to him. He gives due credit to the work of others, but does not hesitate to give his own views, often in considerable detail. It is not always easy to follow the intricacies of etiology and pathology, nor to separate undoubted facts from less well authenticated theories. The more practical subjects are well presented. Medical treatment is abundant and hopeful and surgical procedures are well described. The author has done much work on the chemistry of the saliva, and believes that important questions, especially in hay fever and other inflammatory processes of the mucous membrane, are caused by an altered chemical composition of different secretions. The fourth edition appeared seven years ago, and is consequently to be discarded in favor of this edition, which has been thoroughly revised and enlarged to include recent progress in the science and art of the specialty.

Differential Diagnosis. Volume II. By RICHARD C. CABOT, M.D., Philadelphia and London. W. B. Saunders Company. 1914.

In the second volume of "Differential Diagnosis," Dr. Cabot uses the same method as in the first, namely, the discussion of what he calls the presenting symptom through illustrative cases. In this volume he takes up nineteen common symptoms, such as abdominal tumor, vertigo, diarrhea, hemoptysis, pallor. As an introduction to the discussion of each symptom, Dr. Cabot presents a graphic table of the relative frequency of the causes of each particular symptom and gives a short preliminary discussion. In general, however, the illustrative cases, which have been very carefully selected, make their own discussion, illuminated here and there by some clear cut comment by Dr. Cabot. It is an interesting as well as instructive book and is a happy contrast to the usual method of discussing differential diagnosis.

THE BOSTON Medical and Surgical Journal

An independently owned Journal of Medicine and Surgery, published weekly, under the direction of the Editors and an Advisory Committee, by the BOSTON MEDICAL AND SURGICAL JOURNAL SOCIETY, INC.

THURSDAY, APRIL 8, 1915.

EDITORS.

ROBERT M. GREEN, M.D., *Editor-in-Chief.*
GEORGE G. SMITH, M.D., *Assistant Editor.*
WALTER L. BURRAGE, M.D. } *For the Massachusetts Medical Society.*
FREDERICK T. LORD, M.D. }

COMMITTEE OF CONSULTING EDITORS.

WALTER B. CANNON, M.D. ALLAN J. McLAUGHLIN, M.D.
HARVEY CUSHING, M.D. ROBERT B. OSGOOD, M.D.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States. \$6.56 per year for all foreign countries belonging to the Postal Union.

The editor will be in the editorial office daily, except Wednesday and Sunday, from twelve to one-thirty p. m.

Papers for publication and all other communications for the Editorial Department should be addressed to the Editor, 126 Massachusetts Ave., Boston. Notices and other material for the editorial pages must be received not later than noon on the Saturday preceding the date of publication. Orders for reprints must be returned in writing to the printer with the galley proof of papers. The Journal will furnish the first one hundred reprints for half the cost price.

All letters containing business communications, or referring to the publication, subscription, or advertising department of the Journal, should be addressed to

ERNEST GREGORY, *Manager.*

126 Massachusetts Ave., Corner Boylston St., Boston, Massachusetts.

NEUROLOGICAL HOSPITALS.

THE tendency to maintain hospitals for special branches of medicine appears to have become well established. There are, in every part of the country, hospitals for women, for obstetrics, for children, for cancer, for mental disease, for contagious disorders and for various other branches of the broad medical field. For some reason the neurological side of medicine has not fared so well. This doubtless has been due largely to the fact that disorders of the nervous system, exclusive of mental disease, have been regarded as an integral part of general medicine and so have been included among the patients received in the wards of a general hospital. The importance of the subject has been so far recognized that out-patient departments have been widely established in connection with general hospitals and it must now be considered that such departments form one of the most important elements in the hospital system. In general, however, the hospitals have been nig-

gardly in granting beds for the special study of diseases of the nervous system. This has been doubly unfortunate because, with relatively few exceptions, distinguished physicians in this country have not at the same time been distinguished neurologists, with the natural result that fundamentally important work on the nervous system has not come from the wards of our general hospitals. This is the more to be regretted since the field is one demanding intensive study and men are waiting prepared to give time to such study if proper facilities comparable to those afforded other branches of internal medicine could be secured. There are naturally many advantages in carrying on such investigations in connection with the work of a great general hospital but with the temper apparently prevailing, those primarily interested in the nervous system must look elsewhere for really adequate hospital facilities. We may expect, therefore, unnecessary as it would seem to be, to see hospitals devoted primarily to diseases of the nervous system established in our larger communities, with other branches of medicine subordinated to these disorders. There seems no adequate reason why such hospitals should not be established with a staff composed of men whose knowledge of and interest in the nervous system is paramount, and others as may be necessary to complete the medical and surgical needs of the patients under treatment. In this connection it is always a satisfaction to call attention to the New York Neurological Institute established for the purpose of demonstrating the necessity of such institutions in our larger centers of population, if completely adequate work in diseases of the nervous system, comparable to that accomplished in other departments of medicine, is to be realized. The fifth report of the New York Institute is before us. In his statement to the trustees, Dr. Frederick Peterson, secretary of the medical board, makes the following statement:

"Begun in 1909 as an experiment to determine the need of a special hospital for nervous diseases, each succeeding year has served to demonstrate more and more forcibly the importance of such an institution in New York. The fact which led the founders to this undertaking was briefly: that there is no hospital of the kind on this continent; that general hospitals do not and cannot provide adequately for the care and treatment of nervous disorders; that these par-

icular diseases require, both for diagnosis and treatment, a special knowledge which the general practitioner, with the constant growth of medical science in so many directions, cannot be expected to attain, and particular therapeutic methods which can be made accessible only in a specially equipped hospital; and finally that the vast number of cases of nervous disease, particularly among the poor, was for these reasons being everywhere neglected."

Apart from the statement that general hospitals cannot provide adequately for the care and treatment of nervous disorders, which does not appear to be proved, since no systematic attempt has ever been made to bring it about, we are in entire accord with what Dr. Peterson says. If the ideal of adequate wards, granting the same privileges to the physicians in attendance as are enjoyed by the internists, cannot be secured, the time must come when institutions like the Neurological Institute of New York must be established. Certainly the example set by the New York institution is one which other cities may well emulate. We have in its arrangement a complete hospital, perfectly equipped to care incidentally for surgical cases, for so-called medical cases as they may arise, but primarily for the neglected disorders of the nervous system, both functional and organic in character. It may be that neurology, as an integral department of medicine, may ultimately cease to exist, absorbed into the field of general medicine or surgery or psychiatry, as the case may be, but for the present this consummation, whether desirable or not, is far from being attained. It must be apparent to any candid observer that a large uncultivated field exists which would be far more productive if greater facilities were offered at our hospitals or, in lieu of them, at privately established institutes, whereby men of promise could be encouraged to enter upon work upon the nervous system with expectations of promotion and recognition commensurate with the fundamental importance of the subject.

been attributed to high systolic blood-pressure, particularly in association with arteriosclerosis, which is apparently now becoming recognized as not simply a process in which hardening of the arteries occurs, but a general cardiovascular disease, the progress of which is apt to be characterized by chronic myocardial degeneration and chronic nephritis, as well as by arterial sclerosis. The general condition may be of slight severity, and this local one marked. High blood-pressure and arteriosclerosis are by no means synonymous or coextensive, nor is high blood-pressure necessarily an accompaniment of advanced life. It is quite possible also to have a low blood-pressure in connection with arteriosclerosis, as was shown by an investigation of some twelve thousand veterans at the Gettysburg semi-centennial celebration last July, whose ages ranged from 66 to 98 years. About nine out of ten had arterial sclerosis, but only about one in ten were found to have high blood-pressure.

Various writers have recently called attention to the exaggerated estimate referred to, and some prominent internists are now expressing their satisfaction of what they term "the passing of high blood-pressure," in so far as it has been a fetish. The present situation was well stated by Harlow Brooks in a paper read some months ago before the Medical Association of the Greater City of New York. For from five to ten years past, he said, more or less routine pressure determination had been recorded by most physicians, and it seemed to him that we were now prepared to discuss, from the standpoint of experience, our findings in this respect, and their apparent significance in clinical medicine. At first the enthusiasts had no doubt greatly overrated this significance, and this spirit was still notable in the lay public and press; but unquestionably the pendulum of professional opinion was now well on the reactive swing. He summarized his opinion as follows: High blood-pressure is not a cause, but usually a result; it is not a disease, though the evidence of disease. It is not pathological, but usually, if not always, physiological in intent; it tends more to prolong life than to shorten it. When its cause cannot be removed, it is not to be treated, but to be maintained. This estimate, it is to be understood, refers to the systolic blood-pressure, to observations of which examination of the blood-pressure for clinical purposes was until quite recently almost exclusively limited. It is now becoming quite generally recognized that in order

THE SIGNIFICANCE OF ABNORMAL BLOOD-PRESSURES.

THERE can be little question that of late years, largely because it was the prevailing medical fashion of the day, far too great importance has

to appreciate the proper significance of blood-pressure variations it is necessary to study them in the three phases of systolic pressure, diastolic pressure, and pulse-pressure; the first being the measure of the force of the ventricular contraction, modified by the arterial resistance and less important factors, the second representing the residual pressure maintained by the tonicities of the arterial system, and the third being the difference between the other two.

In a recent contribution on the clinical significance of variations in these different pressures (*International Clinics*, Vol. 1, Series 25) Dr. Edward E. Cornwall of Brooklyn, N. Y., known as an experienced and keen observer, states, very rightly, that this is a particularly difficult subject with which to deal, not only because it is comparatively new and has not yet been thoroughly studied, but because of intrinsic difficulties, since the possibilities of error in observation and of confusion of data are present in an unusual degree. A very useful, though only partial, index to the efficiency of the circulation, however, is afforded, he has found, by the systolic and diastolic pressures considered in their numerical relations—that is, the difference between them, the pulse-pressure, and the relation of this to the pressure scale. The pacemaker for the pulse-pressure, at least in conditions of disease, seems to be the diastolic pressure more often than the systolic. The following are among the conclusions which he has reached, largely as the result of his personal observations: A low systolic pressure, provided the diastolic pressure is sufficiently low to provide an adequate pulse-pressure, does not necessarily mean poor circulation, though it does seem to imply a diminished reserve power of heart. A comparatively low systolic pressure with a comparatively high diastolic pressure and a comparatively small pulse-pressure may mean myocardial weakness with chronic nephritis, arteriosclerosis, chronic toxemia, or arterial spasm. A low diastolic with a comparatively high systolic pressure and an excessively large pulse-pressure may mean several things: *e.g.*, a purely functional condition, a compensated aortic regurgitation, myocardial degeneration without much arterial sclerosis or chronic nephritis, or vasodilatation from any cause. The diastolic pressure seems to be more stable than the systolic, and to show less often marked variations from its normal without definite pathological cause, while in conditions of disease the systolic pres-

sure seems to accommodate itself to the diastolic more readily than the diastolic to the systolic. The diastolic pressure seems to indicate the peripheral resistance, which in many instances is determined by definite pathological conditions, and movements of this pressure beyond the normal range to be a sufficient cause for enlargement of the pulse-pressure if an adequate circulation is to be kept up. A diastolic pressure of 100, or higher, if persistent, or a systolic pressure over 140 in a young or middle-aged adult, suggests disease, while a pulse-pressure as small as 20 or as large as 60, if persistent, may be pathological. A fall in the systolic pressure in response to an exercise test, immediately or after a short preliminary rise, and a delay in its return to normal, and also at the same time a failure of the pulse-pressure to show a substantial increase, suggest myocardial weakness. Chronic nephritis seems regularly to be attended with a high systolic and a large pulse-pressure, an adequate condition so long as the myocardial reserve power holds out. Arteriosclerosis, as a rule, seems to produce marked elevation of the blood-pressure only when the blood supply of a vital region is disturbed or when the aorta is affected. The neurotic factor in the patient and the personal factor in the observer may require considerable allowance to be made for them in the interpretation of blood-pressure findings, and it is necessary to be constantly on guard against being misled by such findings, and especially against ascribing too much importance to them when unsupported by other evidence of disease.

In the latest communication on the clinical significance of blood-pressure (*Medical Record*, March 20, 1915) Percival Nicholson also insists on the importance of a complete blood-pressure picture, stating that the systolic reading alone tells less than half the true situation. In hypertension cases, he remarks, it is not the lowering of blood-pressure which is important, though there are a few exceptions. These he gives as follows: (1) In cases where the pressure is sufficiently high to threaten apoplexy (250 to 300 m.m. Hg.) an immediate reduction of this usually by venesection, is indicated; (2) in hypertension with failing compensation and an overloaded right heart, as in pneumonia, an immediate venesection will often save the patient; (3) angina pectoris presents an urgent indication for the use of vasodilators; (4) in cases in which operative measures are demanded, where

the height of the pressure is such that the administration of an anesthetic is dangerous, a preliminary lowering of it will often permit of a safe operation; (5) in patients with cataract, and having hypertension, a preliminary bleeding will so lower the pressure that a safe enucleation may be performed and the danger of post-operative intra-ocular hemorrhage avoided.

THE SEVENTH PAN-AMERICAN MEDICAL CONGRESS.

THE seventh Pan-American Congress of Medicine is to meet at San Francisco during the week of June 17 to 21 inclusive, assembling pursuant to an invitation by President Wilson, issued in accordance with an act of Congress approved on March 3, 1915. This tardy action of Congress in sanctioning an important medical meeting leaves but short time for preparation and increases the urgent need of coöperation in the profession, to ensure its success.

The first Pan-American Congress was held in the United States in 1893, and the five succeeding congresses have been in the various Latin-American countries. It now devolves upon the physicians of the United States to administer this seventh congress, which, in view of the European war, will presumably be the largest international medical meeting of the year.

The countries and colonies embraced in the congress are the Argentine Republic, Bolivia, Brazil, Canada, Colombia; Cuba, Chile, Costa Rica, El Salvador, Ecuador, Guatamala, Honduras, Haiti, Hawaii, Mexico, Martinique, Nicaragua, Panama, Paraguay, Peru, Santo Domingo, United States, Uruguay, Venezuela, British Guiana, Dutch Guiana, French Guiana, Jamaica, Barbadoes, St. Thomas and St. Vincent. The organization of the Congress is perfected in these countries and the majority of them have signified their intention to be represented by duly accredited delegates.

The Congress will meet in seven sections, *viz.* (1) medicine; (2) surgery; (3) obstetrics and gynecology; (4) anatomy, physiology, pathology and bacteriology; (5) tropical medicine and general sanitation; (6) laryngology, rhinology and otology; (7) medical literature.

All members of the organized medical profession of the constituent countries are eligible and are invited to become registered. The member-

ship fee is \$5.00 and entitles the holder to a complete set of the transactions. Advance registrations are solicited and should be sent with membership fee to the treasurer, Dr. Henry P. Newman, Timken Building, San Diego, California.

The occasion is particularly favorable for a large attendance, not only on account of the Panama-Pacific Exposition at San Francisco and the California Exposition at San Diego, but because this Pan-American Congress immediately precedes the annual meeting of the American Medical Association. Dr. Charles A. L. Reed of Cincinnati is president of the Congress, Dr. Raymond Guiteras of New York City is secretary-general, and Dr. Harry M. Sherman, of San Francisco, chairman of the committee of arrangements.

BOSTON QUARANTINE TRANSFER.

At its meeting on Monday, March 29, the Boston City Council finally passed the order for the transfer of the local quarantine station from municipal to federal control. By this order the mayor is authorized to execute, with the federal government, a lease of the quarantine property, whose terms must be approved by the council before they become effective. Under this lease the quarantine station will be administered by the federal authorities until congress shall appropriate a sum sufficient to permit the purchase of the entire property. The price for which the property shall ultimately be sold is to be determined by a board of arbitration, of which one member is to be selected by the national government, another by the City of Boston, and the third by these two. As soon as the preliminary lease is executed, all the powers of the Boston Board of Health relative to the maintenance of the Quarantine Station become automatically abolished.

THE BOSTON SURGICAL SOCIETY.

IN this week's issue of the JOURNAL we are pleased to publish the first report of the transactions of the Boston Surgical Society, a new medical organization recently incorporated in this city. The first meeting of this society was held in February and all its papers and proceedings are to appear exclusively in the JOURNAL. It has been the policy of the JOURNAL particu-

larly to publish the transactions of local and New England medical societies, and we are glad to be able thus to present to our readers the important work of a new organization among this number, especially one whose membership affords so high promise of worthy contribution to medical literature.

MEDICAL NOTES.

COLD WEATHER BRINGS PNEUMONIA AND GRIP IN NEW YORK.—The most noteworthy feature of the mortality during the past week was the large increase in the number of deaths reported from pneumonia, the total number being 380 as against 305 during the corresponding week of 1914. This was undoubtedly due to the sudden general increase in the prevalence of influenza (grip), the number of deaths from this cause being 28 as against 18 in the corresponding week of 1914. Influenza probably had something to do also with the increase of 19 deaths from pulmonary tuberculosis. The mortality from other infectious diseases was considerably below that of 1914, especially among the deaths reported from measles, scarlet fever, diphtheria and croup and diarrheal diseases.

The death rate of children under five years of age during the past week was considerably lower than that of the corresponding week of 1914, there having been 55 fewer deaths reported.

There were 1750 deaths in this city last week, a death rate of 15.72 per 1,000 of the population as against 1768 deaths and a rate of 16.52 during the corresponding week of 1914. This is a decrease of .8 of a point, equivalent to a relative decrease of 89 deaths. The death rate for the first thirteen weeks of 1915 was 14.22 per thousand of the population as against 15.60 for the corresponding period of 1914, a decrease of 1.38 of a point.

SMALL-POX IN NEW JERSEY.—Report from Melville, N. J., on March 24, states that there are at present thirty-five cases of small-pox in that city, which numbers about 14,000 inhabitants. All schools, churches and other places of public assembly have been closed and extensive vaccination of the unprotected population is being initiated.

TYPHOID MARY AGAIN ISOLATED.—On March 27, Miss Mary Mallon, familiarly known as Typhoid Mary, who is probably the most celebrated "carrier" in medical history, was again apprehended by the New York Board of Health and returned to quarantine for an indefinite period. She has recently been working as a cook at the Sloane Maternity Hospital where twenty-five cases of typhoid fever, with two deaths, have resulted.

EUROPEAN WAR NOTES.—On March 26 a financial report was issued in London by the American Commission for relief in Belgium, showing

that already food stuffs to the value of \$20,000,000 have been delivered in Belgium since the commission began its work. Further supplies valued at \$19,000,000 are now on their way to the country. Over \$1,000,000 worth of clothing has also been distributed.

"Of the grand total, \$8,500,000 was provided by benevolent contributions, either of food or cash, and the balance of \$30,500,000 was provided by banking arrangements set up by the commission.

"The benevolent contributions consisted of \$2,600,000 in cash and \$5,900,000 in foods. Of the benevolent contributions the United States provided \$4,700,000.

"The contributions from the United States include in round numbers; New York, \$1,300,000; Rockefeller Foundation, \$1,000,000; Northwestern Millers, \$550,000; California, \$280,000; Pennsylvania, \$260,000; Kansas, \$240,000; Iowa, \$150,000."

BOSTON AND NEW ENGLAND.

MASSACHUSETTS HOSPITAL APPROPRIATIONS.—There is at present pending before the Massachusetts General Court a bill providing an appropriation of \$1,000,000 for the construction of a metropolitan hospital for the insane on land already purchased for this purpose in Waltham, Mass. The bill is at present in the hands of the committee on public institutions.

Large hospital appropriations, aggregating over \$2,000,000 have already been made this year by the state legislature for hospital purposes, as follows: Norfolk State Hospital, \$117,137.55; School for the Feeble-Minded, \$291,878.23; Rutland Sanatorium, \$149,707.51; Gardner Colony, \$160,299.36; North Reading Sanatorium, \$68,945.42; Foxborough Hospital, \$103,200.37; Lakeville Sanatorium, \$89,043.33; Westborough Hospital, \$254,512.01; Westfield Sanatorium, \$96,977.64; Hospital School, \$41,901.51; Worcester Asylum, \$349,344.17; State Farm, \$359,600; Penikese Hospital, \$27,950.

On April 3 the totals of the principal American relief funds for the European War reached the following amounts:—

	N. Y.	N. E.
Belgian Fund.....	\$1,010,552.55	\$242,795.55
Jewish Fund	598,943.26	55,660.52
Red Cross Fund.....	476,840.75	117,208.58
Amer. Ambulance Hosp....	383,067.02	
Committee of Mercy.....	140,143.16	
Prince of Wales Fund....	115,847.23	
Polish Fund.....		39,643.42
St. George's Fund.....	32,604.39	
British Fund.....		25,539.62
Persian Fund.....	15,659.00	

BOSTON HOSPITAL CONCERTS.—The concerts of the Boston Hospital Music Fund for April have been announced as follows:

April 6—Carney Hospital, 3 P.M.

April 11—St. Luke's Home for Convalescents, 2 P.M.

April 18—Boston Home for Incurables, 2 P.M.

April 27—N. E. Peabody Home for Crippled Children, Hyde Park, 3 P.M.

REPORT OF THE BOARD OF HEALTH OF BROOKLINE.—The report of the Brookline Board of health for the year 1914 gives an interesting account of the administration of public health that community organized under the several departments of vital statistics, bacteriological department, the sanitary agent, the agent for the inspection of animals, the agent for the inspection of provisions and milk, the board of health hospital and the mosquito and fly suppression. Vital statistics show that the mortality rate has decreased from 12.85 per 1,000 inhabitants to 2.49. Plans for the erection of a tuberculosis hospital have been approved and the building is to be constructed as soon as possible.

MASSACHUSETTS HOMEOPATHIC HOSPITAL.—The annual graduation exercises of the Massachusetts Homeopathic Hospital Training School for nurses were held in Boston on March 31. Diplomas were awarded to a class of 34 pupil candidates.

BOSTON LYING-IN HOSPITAL.—The recently published eighty-second report of the Boston Lying-in Hospital records the work and progress of that institution for the calendar year 1914. During this period 789 patients were admitted to the hospital and 1944 were taken care of in their own homes. One thousand seven hundred and ninety-nine patients were treated in the puerperium clinic. The expenses of the hospital exceeded the receipts by \$1,799.23. Thirty-five pupil nurses were graduated from the training school. Last spring a site of land for a new hospital building was purchased near the Harvard Medical School and it is hoped that funds will soon be raised for the erection of the hospital for which the plans have already been drawn. Donations are earnestly invited for this purpose and for the running expenses of the hospital in its present quarters.

PROPOSED CAMBRIDGE CITY HOSPITAL.—Plans for the proposed new Cambridge City Hospital have recently been completed and provide for a large institution of 150 beds to be erected on a site on Cambridge street, bounded by Line street and Camelia avenue.

"At the extreme end of the lot in Line street will be a building containing an engine-room, a boiler-room, from which heat will be transmitted to the hospital by subway; a small morgue, an autopsy-room, a pathological laboratory, a garage for ambulances, sleeping quarters for orderlies and a laundry.

"The new buildings will be of fireproof construction, with exterior walls of waterstruck brick and cast-stone traceries. The roofs will be of slate, with copper trim. In general style the buildings will be Colonial.

"In the basement of the main hospital building there will be an out-patient department and emergency rooms, reached from Camelia avenue; an x-ray department, a dining-room for domes-

tics and orderlies, space for storage, and the hospital kitchen and service rooms.

"The ground floor of the main building, with an entrance in Cambridge street, will contain the administration rooms, dining-rooms for doctors and nurses, diet kitchens, emergency wards, male and female medical wards, the apothecary's room, trustees' room, and at the end of each wing in Cambridge street, a solarium.

"There will be solaria similarly located on the second floor, besides male and female surgical wards, medical and surgical wards for children, a maternity ward, and etherizing, operating and recovery rooms. On the third floor, will be a living-room and sleeping quarters for internes."

It is estimated that this structure will cost at least \$175,000 and its equipment an additional \$30,000. The legislative act providing for this hospital authorized the borrowing of \$150,000 beyond the city's debt limit. The remainder of the amount needed must be met by special appropriation.

FOOT AND MOUTH DISEASE IN CONNECTICUT.—Report from Hartford, Conn., states that on March 24, fifteen towns in New London County were placed under quarantine by the State Cattle Commissioner on account of recent out-breaks of the foot and mouth disease. The towns affected by this order, in which the disease has been discovered, are Bozrah, Franklin, Griswold, Groton, Ledyard, Lisbon, Montville, New London, Norwich, North Stonington, Preston, Sprague, Stonington, Voluntown and Waterford.

REPORT OF THE INFANTS' HOSPITAL.—The recently published thirty-second annual report of the Infants' Hospital of Boston records the work of that institution during the past year and calls attention to its urgent need of funds. Dr. George S. Derby, the medical director, in his report says:

"Our new building was planned not only for the care of sick babies, but also as a model for the instruction of the public, and but little provision was made for private patients. Owing, however, to the lack of funds, it was found imperative to increase our income by the admission of a number of paying patients. To accommodate these, it was necessary to use the model nursery, the premature ward and the house officers' quarters, and to make certain other rearrangements in the hospital. The needs of every hospital are many, and the Infants' forms no exception. First among them we need funds to open our second ward. This is less a need of the hospital than of the general community. We need funds for a stenographer to work on the hospital records, and to relieve the assistant secretary and to release her for other work. We need a general helper to do technical work in the laboratory and in connection with the x-ray department."

Dr. Charles Hunter Dunn, the physician-in-chief, says in part in his report:

"The cases which form the majority of those which have been treated in the new hospital represent the worst types of disease seen in infancy. There is now a very close coöperation among the various institutions treating babies. From the Milk and Baby Hygiene Clinics, the sick babies are referred to the out-patient departments of such hospitals as the Children's, the Boston Dispensary, the Massachusetts General, and others. From these, the worst cases are selected for admission to hospital wards. Except during the short time in summer, when the Floating Hospital is open, there is no other hospital which has so many beds available for babies under two years of age as the Infants' Hospital. Consequently, a large proportion of these bad cases, chosen by a careful process of selection, comes to us. I believe that our results have been very good, considering the character of the cases we have treated. There are still not enough beds available in Boston for the care of all these severe cases needing hospital treatment.

"The work of the social service department has been of inestimable assistance to the work of the medical staff. The investigating and improving of the home surroundings from which our babies come, while they are in the wards, so that they will not go back to the same conditions, is a most important factor in making the work done for the babies in the hospital of permanent benefit to the community. Also, we are enabled, through the social service department, to follow the final results of our treatment and to learn when we were right, and when wrong. This ability to check up the final results of our work will, in time, greatly increase our efficiency."

HOSPITAL BEQUESTS.—The will of the late Dr. Hasket Derby of Boston, filed on March 24 in the Suffolk Probate Court, contains a bequest of \$5,000 to the Carney Hospital.

The will of the late Calvin W. Capen of Dedham, Mass., which was filed in probate court on March 24, leaves a residuary bequest of about \$50,000 to the Elizabeth Capen Fuller Hospital of that town.

Obituary

WILLIAM MURRAY DOBIE, M.D.

Dr. William Murray Dobie, who died at Chester, England, on March 12, was born at Liverpool in 1828. He received his education at the University of Edinburgh, from which he obtained the degree of M.D. in 1849 with honors and the award of a gold medal in surgery. He served as resident physician and surgeon at the Royal Infirmary under Syme and Lister, and after completing his studies subsequently in Berlin, Paris and Dublin, settled in the practice of his profession at Chester.

In 1867, during the epidemic of cholera in that city Dr. Dobie rendered distinguished and courageous service and was largely instrumental in checking the pestilence. In connection with this event he contributed a valuable article on the use of chlorine in the treatment of this disease. In 1875 Dr. Dobie was elected honorary physician to the Chester Infirmary, which he served actively for twenty years, and upon his retirement in 1895, he was elected its consulting physician. He was also honorary consulting physician to the Wrexham Infirmary and to the Royal Alexandria Hospital at Rhyl. He was for many years private physician to the late Mr. William E. Gladstone, whom he attended in his last illness.

In addition to his active medical life, Dr. Dobie maintained an alert and constant interest in other branches of science whose study was his avocation. He was particularly interested in astronomy and microscopy. In 1849 he discovered and described on the moon a new crater which still bears his name. In 1850 he contributed to the *Annals of Natural History* a description of two new species of floscularia and to the Royal Medical Society of Edinburgh a paper on the cilia of grantia. His thesis for his medical degree dealt with the histology of muscular tissue in which his name is still preserved by the term Dobie's line. With Canon Kingsley he was one of the founders of the Natural Science Society and subsequently became its president. He was later awarded the Kingsley medal for the advancement of natural science.

For many years Dr. Dobie had been a familiar and beloved figure in the medical profession and among the communities of Cheshire and North Wales, where he was universally desired by physicians and patients as a consultant. The *British Medical Journal* in its obituary of Dr. Dobie says of him, "He earned and retained the esteem and affection of everyone with whom he came in contact. His skill and success as a physician abundantly bore out the promise of his early scientific training and accomplishment."

Dr. Dobie is survived by his widow and by five daughters and five sons, three of the latter of whom are now medical practitioners in Cheshire.

Miscellany.

MILK LEGISLATION AND INVESTIGATION IN MASSACHUSETTS.

IN the issue of the JOURNAL for Feb. 25, we commented editorially on the labor clean milk bill and in the columns of the JOURNAL for Mar.

25 we published a further editorial, stating the official attitude of the Massachusetts Medical Society on this important subject. At a recent hearing on this bill held before the committee on public health the bill was advocated by the following persons:—

Dr. Charles F. Withington, president of the Massachusetts Medical Society; Councilman William H. Woods, representing the City of Boston; Senator Sanford Bates of Boston; Henry Sterling, representing the American Federation of Labor; George Bedinger, for the Milk and Baby Hygiene Association; George L. Richards of Malden; Representative Edward G. Morris of Boston; Dr. Enos H. Bigelow, former House chairman of the committee on public health; Mrs. Julius Andrews, for the Federation of Women's Clubs; Daniel J. Murphy, chairman of the Lawrence board of health; Howard Whitmore of the United Improvement Association; Councillor William H. Woods for the City of Boston; Dr. W. P. Bowers for the Massachusetts Medical Society.

It was opposed by representatives of the Massachusetts State Grange.

Governor Walsh has recently sent to the legislature a special message on the subject of milk industry, accompanied by a proposed resolve providing for the appointment of a special commission of three to inquire into the subject and report not later than Jan. 10, 1916. The full text of this message and resolve is as follows:—

"To the Honorable Senate and House of Representatives:

"I have already expressed to the legislature my solicitude over the depressed condition of the milk industry, and recommended that a thorough inquiry into its causes be set on foot early enough to make a remedial action possible during the present session. It is now probably too late for such an investigation to be made and its results duly weighed before prorogation, but not too late to arrange for supplying the next legislature with reliable and exhaustive data on this most important subject. Former inquiries have had mainly to do with the charges for transportation, but this should include all the important factors in the case.

"I accordingly transmit herewith a resolve indicating the scope of the inquiry that I believe ought to be made, and recommend its passage with the inclusion of any other topics that the Legislature considers pertinent.

"The facts relating to our milk supply are as startling as their causes are obscure. In the last 25 years, while our population has increased from 2,238,943 to about 3,600,000, or more than 60%, the number of cows in the Commonwealth has decreased from 200,000 to 147,000, or more than 25%. In other words, in 1890 there was one cow to every 11 persons, in 1914 only one to every 22. More than a quarter of the decrease has occurred in the last two years, which would

seem to show that the adverse conditions, instead of moderating, are growing more acute.

"Farm statistics covering the period from 1860 to 1910 show that in the counties of Berkshire, Franklin, Hampden and Hampshire, the improved farm land under cultivation actually shrunk over 50%, from 958,336 acres to 456,486; and the same proportion is said to obtain throughout the state. Meanwhile the price of milk to the consumer has soared from six cents to ten, twelve and fifteen cents a quart, although the farmers are receiving little if any more for their product than when it was retailed at half the present prices. The average distance from which milk is gathered for the metropolitan market has also greatly increased, and with it the average age of the product when consumed; both of which increases are a detriment to its food value, especially for infants and invalids.

"Such conditions cannot be a matter of indifference to the farmers of the Commonwealth, whatever statements to the contrary may be made by any who profess to speak for them. I am confident that they would almost unanimously welcome an investigation that has long been the cause of bitter complaint on their part. Surely it would be welcomed by the great mass of consumers, upon whom the increased price and lessened food value of milk have imposed no inconsiderable burden and hardship. It may even be questioned whether, if a remedy is not soon found, municipalities may not find it necessary to make the milk supply a public function, as they have already done in regard to water, and to a lesser extent in regard to the minor home comforts of gas and electricity.

"At all events, it is our plain duty as public servants, intrusted with the necessary power, not to remain inactive while this most important necessity of life is becoming more and more inaccessible to those who largely depend upon it for health and strength. At the very least, we should attempt to determine whether the people are paying more and the producer receiving less for milk than the conditions warrant, and what, if anything, can now be done to arrest the decline in our milk industry, if we cannot fully restore and develop it.

"(Signed) "DAVID I. WALSH."

On March 18, a hearing on this message and resolve was held before the legislative committee on agriculture and public health. The resolve was opposed by representatives of the state grange and of various milk producers and dealers.

"The resolve provides as follows:—

"Resolved, That the governor, with the advice and consent of the council, shall appoint a special commission of three persons, at least one of whom shall have had experience in milk production, to inquire into the causes of the present and long-standing unsatisfactory condition of the dairy industry in the Commonwealth and to

suggest legislative or other remedies therefor. The commission shall meet at various centres in the Commonwealth and shall have power to summon witnesses and papers and to administer oaths, and refusals to appear and testify or produce papers when summoned by it, shall be punishable as contempt of court. The investigations of the commission shall include the following topics, with any others that it may deem important to a complete understanding of the subject:

"(a) Whether any combination or agreement contrary to public policy artificially reduces the price paid for milk to the producer, or artificially enhances the price paid by the consumer.

"(b) By what means, if any, the number and quality of milch cows kept in the Commonwealth can be increased.

"(c) Whether, and how, the present costs of milk production may be lowered without sacrifice of quality.

"(d) Whether the grading and labelling of milk, with reference to its total solids and butter fat, the time elapsed since milking, or other circumstances affecting its food value, are advisable in the interests of producer or consumer, or both.

"(e) Whether there are wastes in distribution that may be avoided either by coöperation between producers and consumers, by the establishment of municipal receiving and distributing stations, or by otherwise reducing present duplications of service.

"(f) Whether the legislation of recent years has discriminated against the native milk producer in favor of the out-of-state producer; and whether there is need of further legislation regarding out-of-state milk, or of encouraging additional state production by premiums or otherwise.

"(g) Whether the taking over by the state of the transportation of milk to and its distribution in the larger centres of population, somewhat on the model of the parcels post, would be in the public interest.

"The members of the commission shall receive such per diem compensation for actual time of service, and may incur such expenditures for clerical assistance and other purposes as the governor and council may approve, not, however, exceeding in the aggregate for services and expenses the sum of \$10,000; and the commission shall sit forthwith and report its findings and recommendations to the legislature not later than the tenth day of January, 1916, and to the governor in part at such times as he may direct."

On March 26 the joint committees on agriculture and public health reported against the above recommendation of Governor Walsh for the appointment of a commission to investigate milk conditions in Massachusetts. These joint committees, however, reported favorably a bill

of Mayor Curley, to authorize the department of public health to expend \$35,000 annually for the sanitary inspection of dairies outside the state, where milk is produced for sale in Massachusetts.

VENEREAL DISEASE IN THE UNITED STATES NAVY.

WITHIN recent years there has been considerable popular and professional discussion relative to the subject of venereal disease and its prophylaxis in armies and navies. The secretary of the United States navy department has recently issued to all commanding officers in the United States Navy, a circular letter which represents the present attitude of the department toward this important subject. The following sections of this letter seem of particular interest to the profession at this time.

"1. The Secretary desires to call the attention of all commanding officers and, through them, of all medical officers and others concerned, to the subject of the prevalence of venereal disease in the Navy; the methods employed in dealing with these diseases; and especially to arouse renewed interest and activity in *educational* prophylaxis in this connection, looking to the careful and intelligent instruction of the entire naval personnel in these matters, to the end that no man shall be subject to the loss of health and efficiency through ignorance of the serious and sometimes fatal results that may come to those so contaminated, and to all connected with them.

"2. During the last statistical year this class of disease has caused four deaths, 138 discharges for disability, and 141,378 sick days. The total damage to the service may be shown by the statement that venereal disease caused the loss to the service of 456 men for the full period of this year. One ship in the Far East reports that 44% of the crew have become infected with venereal disease of some kind during the cruise. Nearly every medical report that comes in states in substance, 'venereal disease *continues* to give a greater damage rate than any other factor.' This condition is not unusual, but has been equally true for many years past, nor is it intended in any way to intimate that venereal disease is more prevalent in the Navy than in other services or in civil communities from which it comes.

"3. The Council on Health and Public Instruction of the American Medical Association states that these diseases are 'the direct or indirect cause of one-eighth of the hospital practice in New York City'; also, that 'of the deaths from disease of the female reproductive organs, 80% are due to gonorrhea alone'; again, a committee of the New York County Medical Society makes the appalling statement that '200,000 people infected with venereal diseases are walking in the streets of New York.' It must also be remem-

bered that a large number of permanent disabilities and fatalities occur both in civil life and in the Navy from far-reaching complications that are often attributed to other causes, and not recognized as the direct result of venereal infection, such as chronic rheumatic troubles, kidney, heart, brain and other diseased conditions that often follow the original venereal infection, but which may not terminate for months or years.

"4. The expense entailed is worthy of consideration, not alone on account of the time lost, but for the medicaments and appliances required to care for these unfortunates; for instance, argyrol for 1914 cost \$10,800; protargol, \$8,929; one single invoice of salvarsan (the demand for which is increasing day by day) was \$17,000. The total expense for these purposes from all sources would probably show a large part of the medical department appropriation, as well as the Naval Hospital Fund, to be involved. The above is presented simply to show the importance of the subject, and the necessity for every one to do all in his power, both by precept and example, to help toward a better condition of things in this regard. Neither yellow fever, nor cholera, nor plague, nor any of the dread scourges of the world compare with the disastrous results of this constant, ever-present evil. The fact that these diseases are not inherent in the Navy, nor in any way necessarily incident to life in the service makes it particularly reprehensible that such conditions should continue to exist if they can be legitimately controlled.

"5. I desire to call attention to the fact that by far the largest part of our personnel is young (under 25), many of them absolutely ignorant of anything pertaining to sex hygiene, and particularly to the types and manifestations of venereal disease, how it is contracted, or the terrible results that almost invariably follow. These young men are especially entrusted to our care, often from the best of homes, where they have been most carefully surrounded with moral and physical safeguards. Their parents and friends, naturally, expect from this great branch of the Government service every safeguard and incentive that will protect their sons from evil of this kind." * * * * *

"8. The use of the so-called 'preventive or prophylactic packet' is not authorized, and I have been severely criticized in various quarters for my attitude with regard to this measure. The use of this packet I believe to be immoral; it savors of the panderer; and it is wicked to seem to encourage and approve placing in the hands of the men an appliance which will lead them to think that they may indulge in practices which are not sanctioned by moral, military, or civil law, with impunity, and the use of which would tend to subvert and destroy the very foundations of our moral and Christian beliefs and teachings with regard to these sexual matters.

"9. When you consider the youth and immaturity of our personnel, including the midshipmen (our future officers) and apprentices of the service, who are entrusted to my keeping with the strong belief that every good and Christian influence inculcated by many an anxious mother or father will be fostered and even strengthened by the protecting care of the Navy, could you expect me to place, or to allow to be placed, in the hands of these often absolutely innocent boys a 'preventive packet' and to say, or allow to be said to them, or inferred, that there is a possibility, or even the remotest probability, that they may need these 'preventives' while on liberty.

"10. The spectacle of an officer or hospital steward calling up boys in their teens as they are going on leave and handing over these 'preventive packets' is abhorrent to me. It is equivalent to the Government advising these boys that it is right and proper for them to indulge in an evil which perverts their morals. I would not permit a youth in whom I was interested to enlist in a service that would thus give virtual approval to disobeying the teachings of his parents and the dictates of the highest moral code. You may say that the ideal raised is too high and we need not expect young men to live up to the ideal of continence. If so, I cannot agree. It is a duty we cannot shirk to point to the true ideal, to chastity, to a single standard of morals for men and women. If, unhappily, experience has taught us that too few resist temptation, that in no wise lessens our responsibility to seek to guide the youth to whom we owe a solemn duty. We need not hope to induce young men to become strong in will power, firm in resisting temptation, if we say to them: 'Go in the way of sin. We have no admonition to you to refrain from evil. All that we have to say to you is to be careful not to contract disease.' Such admonitions to boys in their teens would make me, as Secretary of the Navy, an apologist for looseness of morals. I could not look a boy in the Navy straight in the face while I appealed to him to lead a clean life, if I were approving the policy and the use of a measure of this kind.

"11. We come now to the main object of this letter, which is to emphasize the fact that our attention has become so engrossed with the purely medical prophylaxis that I feel the *moral prophylaxis* has become neglected, and wish to arouse and reawaken interest and activity in the proper teaching of the personnel with regard to the nature and dangers of venereal diseases, and to ask the hearty co-operation of every officer and man to see, so far as his influence and example go, that every associate and shipmate does not become the victim of any of these diseases through ignorance or the lack of moral support in all that makes for continence, and for a clean and moral life.

"12. Certainly, with this attitude no harm can be done, and while we may not be able to entirely wipe out this great evil, yet it is my

firm conviction that much good will surely result and the bad condition be materially ameliorated.

"13. To this end then it is directed that commanding officers consult with their medical officers, and that a regular and systematic course of instruction be given along the lines indicated in this letter; and it is further directed that such efforts be continued until every man is fully aware of the nature of these diseases and the dangers that will certainly overtake him, if he fails to be guided by these teachings.

"JOSEPHUS DANIELS,
"Secretary of the Navy"

Correspondence

INSPECTION OF OUT-OF-STATE MILK.

WINCHESTER, MASS., March 29, 1915.

Mr. Editor: In your editorial of March 25th on the clean milk bill, Dr. Withington states that Boston is the only place in Massachusetts that examines the source of its out-of-state milk supply. This is an error. About one-third of the milk consumed in Winchester is produced in New Hampshire, and for more than three years the Winchester Milk Inspector has given the dairies producing this milk the same careful inspection that is given to those producing our so-called "local" supply. I had supposed that Brookline and several other municipalities also inspected their out-of-state milk supply, but of this I am not certain.

Respectfully yours,

C. J. ALLEN, M.D.,
Secretary Winchester Board of Health.

RESIGNATION.

It is announced that Dr. Frank H. Holt, who has served as assistant superintendent of the Boston City Hospital for the past eleven years, has resigned to become superintendent of the Michael Reese Hospital in Chicago. His resignation will take effect on April 15, on which date he will have completed twenty-two years of service at the City Hospital.

APPOINTMENTS.

UNIVERSITY OF CALIFORNIA.—Dr. Herbert M. Evans, formerly associate professor of anatomy at the Johns Hopkins University, has been appointed professor in anatomy and director of the department of anatomy of the University of California.

UNIVERSITY OF CHICAGO.—Dr. George William Bartelmez and Dr. Elbert Clark have been appointed assistant professors of anatomy and Dr. Harold S. Adams, instructor in physiology.

RECENT DEATHS.

DR. EDWARD SPRAGUE PECK, who died recently in New York City, graduated from the University of Vermont in 1864 and received the degree of M.D. from the same university in 1868. After practising his profession for seven years he traveled and studied abroad and served for a time in the Serbian army during the Turko-Serbian war. Returning to the United States in 1878 he settled permanently in New York where he practised as a specialist in diseases of the eye, ear and throat. He was associated with the King's County Hospital, King's County Lunatic Asylum, the Northwestern and Eastern Dispensaries, the Bellevue Hospital, the New York City Hospital, St. Elizabeth's Hospital, the Montefiore Home and the Post-Graduate Medical School and Hospital of New York. He was also professor of ophthalmology and otology at the University of Vermont and was a member of various medical organizations. He is survived by his widow, one daughter and three sons.

DR. OLIVER C. SMITH, who died at Hartford, Conn., on March 27, was born in that city in 1859. He received the degree of M.D. from the Long Island Medical School in 1883. He was a Fellow of the American College of Surgeons and president of the Connecticut State Medical Society.

A NEW PREPARATION FOR PYELOGRAPHY.

By EDWARD L. YOUNG, JR., M.D., BOSTON.

Genito-Urinary Surgeon to Out-Patients, Massachusetts General Hospital.

THE various substances used to inject the kidney for the purpose of obtaining an x-ray outline of the pelvis are, and so far as I know, always have been, with a few exceptions, some soluble organic silver preparation. Some form of bismuth, lime water, and oxygen have all been tried, but without success. Ever since the beginning of this procedure, it has been obvious that there is danger of irritation to a greater or less degree, and as time goes on, more cases are reported where there has been a very severe reaction. This varies from the milder cases, with renal colic of one or two days' duration with local tenderness and some general prostration, to the cases with most severe local symptoms, where the kidney has to be decapsulated to save its integrity, and even a few cases resulting in the death of the patient. We have come to recognize the "collargol kidney," so called, which, when we have to decapsulate, shows perinephritic edema and congestion, staining of peripelvic tissues, capsular and subcapsular injection, edema and infiltration with collargol. If there is only a mild reaction and the kidney is operated on within a few days for some other cause, the appearance is again characteristic; the ureter is dark and the vessels on and near it injected. The pelvis is dark and the peripelvic tissue is stained. The whole kidney is congested

and there are areas beneath the capsule which are stained with collargol.

There have been several cases reported ending in death coming on suddenly within a short time after the injection. There have been many cases which demanded drainage. The two cases at the Massachusetts General Hospital in which decapsulation was necessary following collargol injection have already been reported. There have been a number of reports of a smooth and painless injection with local symptoms starting a few hours later and going on to a severe reaction. These have notably been in cases of pyonephrosis or hydronephrosis or when there was an obstruction to the outflow necessitating the remaining behind of a considerable amount of silver salt, in some cases under slight tension. Several writers on the subject end by saying that a few days of reaction are generally unavoidable with tenderness, pain and constitutional symptoms, and advocate what treatment they deem advisable to meet these, in the shape of morphia, poultices over kidneys, etc.

Considerable experimental work has been done which shows the same damage to the kidneys. Eisendrath, using varying degrees of pressure, found with mild force that the collargol was in the peripelvic tissues and under the capsule, and when considerable strength was exerted, even in the lungs and other organs. In these latter cases also, the collargol went by direct extension into the tubules. Keyes, using no force beyond that necessary to distend the pelvis without tension, and even in certain cases putting a small amount in the lower end of the ureter and stopping the injection before the solution reached the pelvis, found microscopically that the collargol had gone into the blood vessels or lymphatics and was to be seen there and in the glom-

eruli. He did not find, however, any evidence of direct extension into the straight tubules.

Spitzer injected 12 c.c. of collargol into a kidney, which showed in the x-ray radiating into kidney substance.

In injecting kidneys post mortem, using no force beyond that necessary just to fill the pelvis, I found in one case that the straight tubules had been filled.

The attempts made to mitigate these difficulties have nearly all been along the lines of technique, that is, injection without force, very slowly and of as small amount and as weak a solution as will give a satisfactory picture. The various details of these factors have varied according to the varied experiences of the men working in this field. So far as I can find, only two attempts have been made with any success at all, using other preparations for the purpose of pyelography. Cargentos, a colloidal solution of silver oxide, has given good results in some cases. A suspension of silver iodide has been advocated by Kelly and Lewis, but has been very little used, as there are objections, first, of putting an insoluble foreign body in the kidney pelvis, and second, of finding a convenient preparation.

We may at this point consider a few facts and theories regarding silver salts, and in particular those used for the purpose under discussion. All silver salts are known to be to a greater or less extent irritating to the lining membranes of the human body. The organic salts were synthesized in the attempt to find some form which while still being efficient as a germicide, would be less irritating when applied to mucous membranes. But even the relatively innocuous argyrol, when used beyond certain concentrations, has considerable irritating effect in the urethra, though in the throat much higher strength can be used. This irritation is due to the reaction of the lining cells to the absorbed drug, for irritation is an early manifestation of poison, and the amount of poisoning done the body cells and tissue depends on the amount of any given chemical which is absorbed. Absorption demands first and foremost that the drug be soluble, while the rate of absorption depends on the particular surface with which the solution is in contact. For instance, the soluble products of metabolism are absorbed rapidly from the upper gut, while if the same products are introduced by rectum they enter the circulation more slowly. Signs of irritation also can occur in the organs in or by which the drug is excreted, as seen in the familiar example of too large doses of urotropin. In cases where a known soluble poison has been taken by mouth, one of the first efforts is, if possible, to add some other chemical which will by reaction render the original offender insoluble and hence relatively harmless.

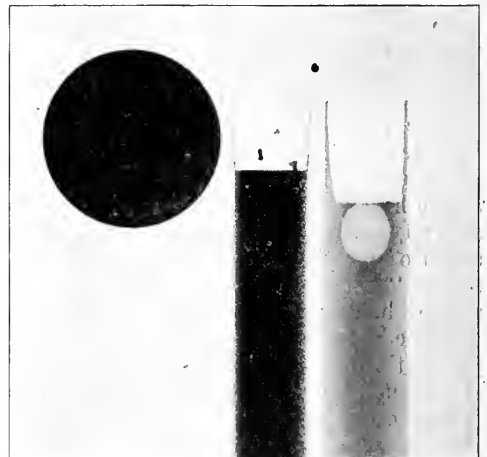

While the fact that the presence of collargol in the kidney is irritating has been long known, it is only comparatively recently that the why of the question has been studied, and, as said

before, these investigations seem to show that collargol gets out of the pelvis and into the kidney apparently in two ways: first, by absorption into the vessels or lymphatics about the pelvis and calices and reëxcretion into the glomeruli; and second, and only when undue force is used, by direct extension into the tubules. On the evidence presented both clinically and experimentally, I believe that we must consider collargol and the other soluble silver salts as absorbable poisons when injected into the renal pelvis and the damage done due to two factors: first, the already recognized mechanical one of force and speed of injection; and second, the factor so far little considered, of the absorbability and reëxcretion. The mechanical factor is well recognized and has, I believe, been intelligently dealt with.

On theoretical grounds, any attempt to find a satisfactory substance for pyelography among the soluble silver salts should be disregarded and our attention should be turned toward the insoluble forms.

About one and a half years ago, Kelly and Lewis reported the use of a 5% emulsion of silver iodide for pyelography. They claimed that it was non-irritating and gave a good shadow. Others who tried it found it impossible to use satisfactorily, for when the mucilage was stiff enough to hold the iodide in suspension, it was too stiff to use, and when thin enough to inject, it was worthless as a suspension and, moreover, had the danger of leaving behind in the pelvis a foreign substance. It was tried in Rochester and Boston, and doubtless elsewhere, but was discarded as useless. Their work was sufficiently convincing, however, to suggest further research, the results of which I am now presenting.

The fact that a 5% suspension throws a better shadow than 10% collargol was easily established, as is shown in the accompanying x-ray. (Plate No. 1.)

From x-ray department of Massachusetts General Hospital.

PLATE NO. 1.

Five per cent. argenticide on left and ten per cent. collargol on right.

Believing that the main difficulties to be overcome lay in the vehicle for the suspension, I asked Mr. Joseph Godsoe, the pharmacist at the Massachusetts General Hospital, about ten months ago, to see what he could find. The necessary requisites are: a substance in itself non-irritating and sterile, sufficiently fluid to flow easily through a ureter catheter, and easily and quickly soluble and diffusible in water in order to fill evenly a kidney pelvis, not form any coagulum, and to leave the kidney pelvis as readily. Mucilage of quince seed was selected as offering the greatest possibilities. This was the vehicle used by Siter in 1905 when he used silver iodide in urethritis. We found, however, that any mucilage we made always became contaminated with a fungus in a short time. Moreover, dilution with water to make thin enough to use, resulted in a poor suspension.

The following is the method used by Mr. Godsoe: Quince seed, 100 grains, water 8 oz. Macerate for 24 hours with frequent agitation. Do not crush the seed. Strain through cloth. Add 2% boric acid up to 20 oz. It is important to extract with water and not with the boric acid solution, as boric acid solution does not make a good mucilage. Enough of this mucilage is added to 12½ c.c. of argentide to make 50 c.c., and vigorously shaken for two minutes. Again, the shaking is an essential part of the process. The resulting emulsion lasts several weeks, and is a thin, clear fluid flowing readily through a ureter catheter. It is on the method of preparation and the character of the resulting emulsion that the value of this substance depends.

The following experiments were undertaken to see what effect the emulsion had in the kidney. First, two guinea-pigs were inoculated, with negative results both in macroscopical and microscopical examinations of the kidneys, but as they had to be killed before coming out of ether, dogs were used.

EXPERIMENT 1. The bladder of a small dog was opened and the ureters catheterized; the kidneys were exposed. In the left 1 c.c. and in the right ¾ of one c.c. of the emulsion were allowed to run slowly by gravity, giving apparent moderate distention. The catheters, which obturated, were removed within one minute, the dog killed one-half hour later. There was no evidence macroscopically or microscopically of any penetration into the kidney or absorption by vessels. The pelvis contained the larger part of the suspension.

EXPERIMENT 2. The same sized dog was selected and the bladder opened and ureters catheterized and the same amounts injected, the pressure being continuous 3 minutes and the dog killed one hour later. The macroscopical and microscopical examinations were again negative.

EXPERIMENT 3. With the same technic the left kidney was injected with ¾ of a c.c., continuous pressure for 3 minutes. On the right, however, 2½ c.c. were injected, using for one minute as much pressure as I thought could be borne without actual

rupture of the pelvis. This dog was killed 30 hours later. The left side showed a slightly congested kidney with no other macroscopic change externally. On section the pelvis contained some of the emulsion, it was slightly reddened, more so around the papillae. Microscopically there was no evidence of penetration or absorption though the congestion was as noted. The right ureter was dilated and blackened, the peripelvic tissues matted together and edematous. The kidney was enlarged and capsular veins congested. On section, the pelvis and calices were much congested, and in one place, extending from a papilla to the cortex about 2 mm. wide, was an infarct of emulsion in the tubules. There was no evidence of subcapsular deposit nor was any of the emulsion seen outside the pelvis, aside from the one infarct noted. Microscopically the above observations were confirmed.

EXPERIMENT 4. The right ureter was injected with ¾ of a c.c. and then tied. The dog was killed 30 hours later. The kidney and ureter were much congested, as was the pelvis on section, but nowhere, either macroscopically or microscopically, was there evidence of the emulsion outside of the pelvis of the kidney.

EXPERIMENT 5. The right side was injected with 1 c.c. of a watery suspension of the argentide and the left with the same amount of the mucilage without the silver salt. Twenty-four hours later the left side showed no reaction of any kind; on the right there was moderate congestion, but neither macroscopically nor microscopically was there any evidence of absorption or penetration.

EXPERIMENT 6. The right kidney was injected with 1 c.c. of 10% collargol and the left with 1 c.c. of 5% argentide emulsion, both under as nearly equal conditions as possible. The dog was killed 48 hours later. The left shows the same picture as noted above, while the right was more enlarged and congested, the peripelvic tissues edematous and slightly stained. There are two spots of subcapsular infiltration. The ureters are markedly different. I think the picture conveys a fair idea of the condition. (Plate 2.)

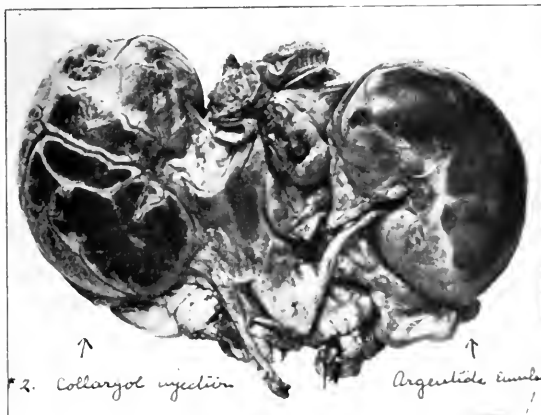

PLATE No. 2.

In all these experiments, with the one exception, the injection was made as gently as in the human patients.

These show, I think, that this preparation is not, as Kelly and Lewis claimed for their emul-

sion, entirely non-irritating, but it does fulfil the theoretical requirements laid down above in that it is non-absorbable and hence only slightly irritating.

We have used this emulsion on the genito-urinary service at the Massachusetts General Hospital for about three months with uniformly good results as regards pictures, far better than with collargol. There have been no cases with anything more than the temporary reaction caused by the cystoscopy and the filling of the renal pelvis, and no untoward after-results. We have taken x-rays one, two and three days afterward in several cases. In two, both pathological pelvises, there was a marked residue the next day. In one this was, however, gone the second day. The other showed small shadows five days later. The kidney was removed the sixth day following injection. On section there were very fine specks of argentide in a few spots near the flattened papillae, not adherent to mucous membrane. The pyonephrotic cavity was remarkably clean, considering the previous pus from that side. Microscopically there was no evidence of absorption. In two other cases there was a very slight doubtful residue the day after by x-ray. In three cases the kidney was operated on, one in twenty-four hours, and one in forty-eight hours, and one in six days. The first one was exposed, the upper part of the ureter and pelvis carefully examined, and finally opened. There was no evidence of irritation and none of the emulsion seen. This was a case

of double pelvis and ureter with bleeding from the upper pelvis. The upper pelvis was injected, the lower one was not. At operation absolutely no difference could be seen in the appearance. The second case was a pyonephrosis, where the kidney was removed. Three c.c. of the emulsion was injected. The picture showed the destroyed character of the kidney very well. (Plate No. 3.) There was no macroscopic or microscopic evidence of the argentide anywhere in or around the pelvis or kidney. This kidney was estimated to have held at least 25 c.c., so that the shadows were thrown by about $\frac{1}{2}$ to 1% strength. The third, described above, was a pyonephrosis, and the shadow is thrown by 3 c.c. of emulsion. The cavity held about 15 or 20 c.c. (Plate No. 4.)

I wish to call attention to three points of technique only. We use the barrel of a 10 c.c. syringe as the container, from which the emulsion flows into the pelvis. When the pictures are taken this is disconnected from the catheter, emptied, the piston inserted and as much of the emulsion as possible sucked out of the kidney pelvis. In the majority of the cases we can recover the larger part. The pelvis is then washed out once or twice with boric acid or salt solution. In all of the work with these cases small amounts, in no case over 3 c.c., have given us good shadows.

Summary. Collargol is an absorbable kidney poison when used in the renal pelvis.

The emulsion of argentide, as described here, is a clean, non-absorbable, opaque fluid, which can be used with the minimum danger to the

patient and maximum satisfaction to the surgeon.

(NOTE.—Silver iodide itself cannot be used for this preparation, but an accurately made saturated solution. Since this latter is somewhat difficult to make, and if not right may be irritating, I have simplified the formula by using a saturated solution already on the market.)

COMMUNICABLE DISEASES AND THEIR RELATION TO THE HANDLING OF FOOD.

ON Tuesday, January 19, 1915, a conference on communicable diseases and their relation to the handling of food was held at the Twentieth Century Club, Boston, under the auspices of the Boston Association for the Relief and Control of Tuberculosis. Dr. Edward O. Otis of Boston occupied the chair as presiding officer.

I.

INTRODUCTORY REMARKS.

BY EDWARD O. OTIS, M.D., BOSTON.

THAT food and drink may be a ready means of conveying disease is a generally recognized

fact now that we know that most contagious diseases are communicated by specific germs.

The water used for drinking purposes may carry infectious germs or the food we eat may contain them.

When large bodies of men are assembled as in armies, the most solicitous attention is given by the sanitary department to the safeguard of the water and food supply, so that the fighting force may not be impaired by epidemics of communicable diseases spread by means of contaminated water or food.

One obvious source of danger is the contamination of food thru its preparation and handling by those afflicted with contagious diseases. Cases in which disease has been communicated in this way are not infrequent. I have only to refer, for example, to the epidemics caused by milk infected by some person who was suffering from a contagious disease. The epidemic of infectious tonsillitis which occurred in this vicinity a few years ago was caused in this way.

Typhoid fever is also spread thru contaminated food as well as by impure water. Not long ago at a church dinner in the city of Hanford, Calif., 84 persons who partook at that dinner of a dish of Spanish spaghetti contracted typhoid fever, and on investigation it was found that this dish had been prepared by a woman who was a typhoid carrier—and thru her, by the medium of the spaghetti dish, the germs of the disease had been communicated to the unfortunate sufferers.

Besides the acute infectious diseases which can thus be communicated—and the source of which is more easily traced, since the cause and effect are so direct and rapid, there are chronic, contagious diseases which undoubtedly can be conveyed thru the handling of food, especially tuberculosis and syphilis. Because, however, they are chronic and of slow incubation it is more difficult to trace them. No one, however, would care to be served with food by a person suffering from either of these diseases, or have their food prepared by such a person. The only way to avoid such a possibility would appear to be to require an examination on the part of the employer of all employees who prepare and handle food—but that is a question for us to consider.

As regards tuberculosis one of the ways in which the disease is conveyed is by ingestion—the entrance of the tubercle bacilli into the alimentary canal, and food contaminated with these bacilli is one way in which this may occur. Consequently it can readily be seen that those suffering from active pulmonary tuberculosis and coughing may infect the food they prepare or handle.

The records of tuberculosis dispensaries show that there is not an inconsiderable number of tuberculous individuals employed as cooks or waiters in hotels and restaurants. For example, in one such dispensary in this city, from July 1 to December 1, 1914, there were 66 cases of well marked tuberculous infection in these occupations, more than half of them having reached the second or third stage of the disease. To give a few examples:—

A colored waiter in one of the hotels, in a very active stage of the disease.

A Greek waiter in a hotel in the advanced stage of the disease.

A pastry cook in a large hotel for 7 years with advanced, active tuberculosis.

Second cook in a large restaurant—very advanced case—sent to State Tuberculosis Hospital at Tewksbury.

Italian pastry cook at one of the largest and best hotels—advanced disease in both lungs and in the throat. Board of Health notified the hotel management to discontinue his services, and he was sent back to Italy.

That this danger has been recognized by employers of those who prepare and serve food is shown by the regulations—for example, of the Pennsylvania Railroad, where some 13,000 people are served every day, which requires that all employees in the railroad's restaurants and dining cars, who have to do with the preparation or serving of food, must be examined at least once every 30 days and oftener if for any reason it is thought advisable.

At the Bellevue Stratford Hotel, Philadelphia, a strict physical examination with sputum and lung tests is given to all candidates for employment. A monthly examination is also given to

those who come in contact with guests in such a way that their ill health would be a source of danger, or to those who handle food.

Recently a bill was passed by the State Legislature of Pennsylvania, which, however, did not become a law, requiring every hotel employer to furnish a medical certificate for every employee, showing a clean bill of health, the cost to be sustained by the hotel employer.

This conference has been called to consider this whole subject of communicable diseases in relation to the handling of food—and from various standpoints—from that of the sanitarian, of the employer, and of the employee.

FIRST:

we wish to consider how great the danger is, and,

SECOND:

what public or private measures are feasible to obviate it.

As the first speaker, I have great pleasure in presenting to you the Commissioner of Health of the State of Massachusetts, Dr. McLaughlin.

II.

DANGERS IN HANDLING FOOD BY PERSONS AFFLICTED WITH COMMUNICABLE DISEASES.

BY ALLAN J. McLAUGHLIN, M.D., BOSTON.

State Health Commissioner.

IN view of the limited time allotted to the speakers (and I may say that it suits me exactly), I think I shall confine myself to the dangers of the so-called water-borne diseases, mis-called, with which I am most familiar. The danger of the transmission of disease by food is far greater than people appreciate. It has not received the attention which it deserves. For instance, in typhoid fever, our first thought is water; our second thought is milk. In the suppression of typhoid fever, we are able to eliminate water absolutely by taking proper measures. We have been able to do a great deal with milk, in the improvement of the milk supply, and yet, after all this is done, we have a rate of from five to ten deaths per one hundred thousand population, due to what we call residual typhoid; that is, what is left, and people have usually been satisfied with that; thought that was to be expected, and that no further measures were necessary. A good health officer considered his duty was fully performed when he had eliminated water and milk, and I may say that in this country, in a great many places, they have not gone that far yet. In Europe, it is easy to find what this residual typhoid is, because there they have eliminated water, and in many cases there is no milk problem. For instance, in the city of Naples, they have a water supply from an uninhabited mountain water shed, which comes through an old Roman aqueduct, and is absolutely pure. They have no milk problem,

because the Italian is a very suspicious individual, and he insists on seeing the milk come from the cow or from the goat into the receptacle that he brings out. They are very poor, and cannot afford to have ice, so the first thing they do is to boil the milk; not to kill the germs, but to preserve it. So practically milk is eliminated. It is largely so all over Europe. They do not use as much milk as Americans do, and, as a rule, they boil it before they use it. Even there, they have a rate of from five to ten deaths per hundred thousand, due to these other factors, which we call residual typhoid.

Now, what are the factors that go to make up this residual typhoid? You are all familiar with the three R's in early education. We have the so-called three F's in typhoid—fingers, food and flies. Whatever we may think about the fly as a more or less acknowledged factor in this, we must consider that fingers and food have a greater influence. The two must be considered, together, and as a combination, outside of water and milk, they constitute the biggest factor in the spread of typhoid. This contact factor, in which food and fingers play such a part, is the primitive way in which this disease has been perpetuated from early times, because in prehistoric times there was no such thing as a public water supply or a public milk supply, and family life was very close and intimate. This disease came down through the ages by means of fingers and food, and today, the more nearly we approach the primitive in the tenement houses in the city, the greater the transmission of disease by this contact method.

The previous speaker has mentioned the Hanford epidemic, and I am very glad he did. It is a very striking example which occurred within a very short time, showing what one dirty hand can do in the way of causing sudden death. This woman prepared the spaghetti at her own home, and, expecting to rebake it to some extent at the dinner, she prepared it and undoubtedly infected it with her dirty hands in the morning, and left it there to incubate in a very favorable medium, in which the germs enormously increased; then gave it further incubation at a very slight heat. To show that this heat would not kill the germs, they made an experiment, and using the same kind of an oven and sufficient heat to just nicely brown the top of the spaghetti, they found that the temperature in the interior was only 70 degrees Fahrenheit, which was nothing more than a comfortable incubation period for the germs. The result was that of the 150 people at the dinner ninety-three came down with typhoid, and while the ordinary period of incubation of typhoid is usually about fourteen days, on the average, in this outbreak it was less than seven days, showing that the dose of typhoid organisms that they must have received with this spaghetti was very large.

Cholera is very like typhoid. They are sister diseases in the matter of their transmission.

We had a mysterious outbreak of cholera in a Manila prison in the Philippine Islands. At times we would have cholera in the remote provinces, but there would be no cholera within one hundred miles of Manila. Cholera broke out in a prison where we had the absolute control of the food and water supply for the institution, and also perfect control, if you will, over the prisoners. I suspected it was a question of fingers and food, and we took three hundred of those who had to do with the food; the cooks, waiters and others who had anything to do, even to the peeling of potatoes, in any way, with the food supply of the institution. Of those three hundred, we got 6% of cholera carriers. They were not sick at all, but those 6% were carrying cholera in their discharges, and with their personal habits, you can readily understand that there was plenty of opportunity to cause these cases which were happening from time to time.

A striking example at the Presidency General Hospital in Calcutta illustrates the point further. They had an outbreak where ten nurses came down, and six died. They all ate at the same table, and they had a new serving boy at that particular table. Professor Hafkin investigated the epidemic and found cholera germs in the remains of food; he found them in the water bucket in which they kept water to carry them over the period when the water was shut off. In this water bucket they had a dipper with a handle, which the boy was in the habit of dipping into the bucket, and sometimes his hand went in with the dipper. The professor took those two boys who handled the food, washed their hands in sterile water in a sterile vessel, and then he made a broth of that, which favors the cholera organism particularly, and had no trouble in recovering the germs from the water in which he washed their hands, showing that cholera germs were on the boys' hands. One of the boys had just washed his hands; at least, he said he had, but it was in a perfunctory way.

One other instance I will cite, and that was in 1908, in Manila. We had an outbreak in an American boarding house. We had a couple of deaths, and four or five cases which recovered. They had a meal in the evening, and at this meal there was served a dessert, some kind of a disturbance; I don't know what you would call it. It was made of gelatine, with a certain amount of fruit in it, and over this disturbance there was poured a custard-like dressing; a kind of a thin custard. To save time, this custard had been prepared by a Philippino cook in the morning, and left for the evening meal. You could not have made a better medium for the cholera organism. The cook had undoubtedly plunged his dirty fingers in this dressing, and left it to incubate through the day, and in the evening, when it was served on that dessert, it gave this terrible result. We went up there to get the boys, to examine them and find out if they were carriers, which Professor Hafkin was

able to demonstrate in Calcutta, but they had both escaped. They heard we were coming, and got away, but undoubtedly one of those boys was a cholera carrier.

The control of water and milk is easy, compared to the other factor, taking care of the contact in the family; of the carrier of disease, who is not sick, but who may be handing you your meals at a restaurant, on a Pullman car, or on a boat. It is a very serious problem, and difficult to handle. Suppose you knew all the carriers. You could not shut them up in jail. Many of them are bread winners. You possibly could prevent them from engaging in certain vocations, I think, with justice. It is a difficult problem at best, and after all, it is not possible to know all the carriers. You could not possibly hope for it. There must be some other way of making this particular factor less effective in causing disease. I think that way lies in general education in personal hygiene. In fact, it is the only way we will ever reach the causative factors in these diseases. You see that is a very difficult thing. You never can get all the people to do it. But you can get constant improvement, and in the end, effect great improvement in this way. People are not dirty from choice, as a rule; they are dirty from a combination of causes; ignorance, and lack of facilities for being clean, largely. The ignorance factor can be combated by public education; by the great agencies which we have now going down among the people: the district nursing associations, anti-tubercular associations, settlement workers, and other agencies which we have. They can do a great deal in combating this ignorance, and also we can look out and see by our building ordinances that they have proper facilities for keeping clean.

Then there is that other great group which is a perpetual danger to us, those who are handling our food supply. A great deal can be done by furnishing them with proper facilities. That is, the employers in hotels and restaurants can see that it is made easy for those people to keep clean. It takes some effort, under certain conditions, to keep clean. I have been myself in a country where I have been expected to take a bath in a teacup. It takes a certain amount of moral courage to go through it in that way, but by making it easy, there is no excuse. I repeat. I believe people are not dirty from choice. I think they are often dirty from the combination of circumstances which surrounds them.

III.

DANGERS IN HANDLING FOOD BY PERSONS AFFLICTED WITH COMMUNICABLE DISEASES.

By HARRY LINENTHAL, M.D., BOSTON.

THE general proposition that it is dangerous for a person suffering from a communicable dis-

ease, or for one who is a carrier of the germs of such a disease to handle food products, is so well known that very little evidence is needed to establish the fact. Any health officer who has had anything to do with communicable diseases can point to his own experience to show extensive outbreaks of contagious diseases due to infected food. I have myself had occasion to trace a number of outbreaks of typhoid fever, scarlet fever, and septic sore throats, which were due to contaminated milk, infected by persons suffering from those diseases or, as is frequently the case in typhoid fever, by persons who were well, but who were carriers of the typhoid germs. The intimate and extensive relations which exist in present society are such that if a farmer on some distant farm fails to wash his hands in the morning, an outbreak of disease is apt to occur in a community hundreds of miles away from that farm.

Milk, however, is not the only source by which infection can be carried, as evidenced by the recent epidemic in California, where ninety-three persons contracted typhoid fever from a dish of spaghetti infected by a typhoid carrier in its preparation.

While it is comparatively easy to obtain epidemiological evidence of infection of food where large masses of people became infected, it is a very difficult matter, and most often impossible to demonstrate the source of infection of the sporadic case of contagious disease. Yet I think it is fair to assume that in many such sporadic cases the infection has been transmitted by food or food utensils handled by a person who was ill with the disease. In a disease like tuberculosis, which has such an insidious onset, it is impossible to trace the source of infection of any one case, but that the danger from infected food is real cannot be denied. The danger not only comes from coughing or sneezing, contaminating the food in that way, but from the handling of the food by persons ill with tuberculosis. There is experimental evidence to show that cultures of tubercle bacilli may be obtained from the hands of patients suffering from tuberculosis, after the ordinary perfunctory washing of the hands.

The danger from hand infection is extremely important in certain industries; I wonder how many of you have ever seen the process of dipping chocolates. The chocolate dipper has a tray of semi-liquid chocolate in front of her, and a tray with the hard candy filling. She picks up the hard candy, and literally washes her hands in the liquid chocolate until the candy is covered. The tray with the chocolate is exposed in front of her continually, and the possibility of infection is many times greater than under certain conditions where the exposure of the food is only momentary, such as is the case of a waiter, for instance, serving an order. You perhaps know that it is only the better class of candy that is dipped by hand. The cheaper grades are dipped by machinery, in a very cleanly way. The reason probably is that we insist that there

shall be a little frill on the top of the chocolate, and that can only be made by hand dipping. We demand a stimulation of our esthetic sense when our food is served to us, frequently at the expense of extremely unesthetic handling of the food in its preparation.

In this connection I would call attention to the practice in certain restaurants of serving some kinds of meats, such as chicken croquettes or lamb chops, with a little ornament consisting of a curled paper around a small stick. I never could quite understand the purpose of this ornament but it occurred to me that possibly the sagacious chef who originated the custom knew that the stimulation of the esthetic sense is productive of good digestion. The principle of the practice is very good physiologically, but its application is rather questionable. That ornament never particularly appealed to me, but I remained indifferent to it until some years ago I happened to be in a tenement house, one of the very worst in the West End, and I found a woman engaged in making these little paper ornaments for hotels and restaurants. I shall not attempt to describe the condition of the room and premises where these were made, but I will say that since then I much prefer to have my meats served unornamented.

The question of the proper handling of food not only relates to the danger of infection but is a question of general hygiene and cleanliness that we would like to know exists in the preparation and handling of our food supplies. Now what is the remedy? How can we guard our food supplies? To some, the solution is very simple and obvious. Enact a law, prohibiting any one who is either a carrier or is infected by disease from handling any food product. Such a solution is impracticable at the present time for the reason that there is not a sufficient public sentiment behind it. Any law which lacks the support of the public, is of no value.

The keynote of the situation, as Dr. McLaughlin has stated, is the education of the public; teach the public to demand that its food be handed to it in a cleanly way. This will accomplish a great deal more than legislation, at the present time, at any rate. Legislation may follow afterwards. I shall not enter into the ordinary methods that have proven of service in the education of the public, they are well known to the Association for the Relief and Control of Tuberculosis that has done such splendid work in its tuberculosis campaign. Such methods include press notices, lectures at women's organizations, labor organizations, exhibits, etc.

I wish to make the following suggestion which seems to me practical: A committee should be appointed by the Boston Association for Relief and Control of Tuberculosis. This committee in consultation with the Health Commissioner of Massachusetts should draw up regulations for various establishments where food is either prepared or handled. An effort should then be made to enlist the coöperation of several pro-

gressive firms by getting them to adopt such regulations. The more enlightened manufacturers could be made to realize that the adoption of such regulations would be an investment and would bring returns in increased output of the products they handle. To get such returns these firms would advertise that their products are put up in accordance with regulations approved by the Health Commissioner of Massachusetts. Not only would the adoption of such regulations set a standard for other firms to follow but by their advertisement would help to create a demand on the part of the public for pure, clean food.

Before closing I wish to call attention to one other aspect of the problem. A widespread educational campaign on the dangers of having food handled by persons ill with communicable diseases, and the adoption of certain standards by firms engaged in the manufacture or handling of food products would prevent some persons ill with tuberculosis from looking for employment in such industries. I recall the case of a young girl I saw about five or six years ago, who gave up her work in a department store because she was suffering from advanced pulmonary tuberculosis and she found the work too hard for her. She decided to look for easier work. At one time, she had had a little experience in chocolate dipping, and she decided she would go back and become a chocolate dipper. I have no doubt a great many instances of that kind occur, where patients suffering from tuberculosis will give up one kind of work because it proves too hard for them, and look for easier work, and very often the easier work lies in some line where they expose food to infection. If the public were educated to the fact that people who handle food supplies must be free from disease, perhaps a great many such cases might be prevented.

DR. CLEVELAND FLOYD. Very striking examples of the way cholera and typhoid fever may be spread by means of food supplies are well known and it is well to remember that equally striking examples exist of where tuberculosis may have been carried through food supplies. We probably all have read of the experience of one physician in New York City, who noticed in getting on a street car that the conductor, who had been coughing, put the transfer that was given to him into his mouth, holding it there a few minutes before giving it to him. He decided not to use that transfer, but took it home and washed it in a sterile solution, then made a smear, and obtained tubercle bacilli from it. This is of importance in regard to the preparation of food, because we all know the women who pick out our chocolates when we want them assorted at the candy store, also lick on the labels on the outside of the packages. In that way, we have, if they have tuberculosis, a very convenient means of contaminating the chocolates we are going to consume.

I also have run across a very striking instance of infection of utensils, where there was a boy who was dying from tuberculosis, and a man

who frequently went into the house as a friend. The boy had an abhorrence of tuberculosis, and to encourage him, this friend used to drink from the same cup which the boy took his milk from, immediately after the boy had taken his portion. A short time after the boy had died, we saw this man and he had a well-marked case of pulmonary tuberculosis. As far as we could find out, that was the only method by which he could have acquired it. If this means anything to us, it demonstrates that we may acquire tuberculosis by ingestion from the handling of food by infected fingers and different utensils.

IV.

TUBERCULOSIS IN ITS RELATION TO THE HANDLING OF FOOD.

By CLEVELAND FLOYD, M.D., BOSTON,

Director, Out-Patient Clinic, Boston Consumptives' Hospital.

THE problem of tuberculosis in connection with the handling of public food supplies has appeared, during the past seven or eight years to those dealing with the question, through the Boston Consumptives Hospital as one of increasing importance. The chief places where tuberculosis, food, and the public meet are in our bakeshops, our restaurants and hotel cafés and their adjoining kitchens. This by no means covers those occupations in which the tuberculous patient is employed in the preparation of food, and while not infrequently the chocolate dippers in our candy factories, the cracker makers and fruit handlers have been found to be actively diseased, they are in the minority.

During the past seven years, among some six thousand cases of tuberculosis examined and provided for by the Boston Consumptives Hospital there occurred among those giving their occupation as cooks 56 cases, among waiters 109, among bakers 16, making a total of about 181 or 2% of all cases of tuberculosis reporting to us.

Investigation of these 181 cases showed the duration of illness to have varied between a few weeks to three years when they first reported for examination. One-third of this number showed from their sputum that they were throwing off tubercle bacilli when we first got in touch with them. It would seem, therefore, to be certain that a large number of these patients were actively supplying the public with food, many for a period of months or years, while suffering with a disease dangerous to public health in its most active form.

It is of further interest to note that almost without exception, when these patients were first reached by the Consumptives Hospital Clinic, they had voluntarily given up work because of not being equal to its demands.

The distribution of these patients among hotels and restaurants has been fairly uniform ex-

cept among those houses which employ Greeks. Here the percentage of the tuberculous seems to be much higher. Such is the condition as found by only one institution in Boston and if it were possible to obtain accurate figures from all the medical institutions of the city together with those of private physicians the number of active cases of pulmonary tuberculosis among our food purveyors would be very largely increased.

From any point of view, whether from that of the employer, the employees or the public, this situation is one of importance. From the point of view of the public, the idea of having its food passed through diseased hands is revolting. Its danger is not a negligible one and is merely one of many sources of infection to the public at large. From the point of view of the employee, disability from disease is a very serious one, discontent with situation and occupation often go hand in hand with it and unreliability may frequently become the resulting characteristic of persons so afflicted. From the point of view of the employer the reputation of his house is all important and as the public becomes more and more educated as to the cause and spread of disease, the unsavory conditions pertaining in relation to the handling of food will be sought out, and correction demanded. Those business concerns that shall anticipate this movement cannot but be the gainers thereby. Anything which impairs the working power or the working force of a business enterprise is of serious detriment to it through the loss of time, inadequate service and engendered dissatisfaction. The public and the employer have a duty towards the employed as well as has the individual who serves the public to it and his employer. The problem of tuberculosis among those handling public food supplies, while important in itself, is only part of the great problem of health among the working class in any line. In Boston this disease can be fully met and in time controlled if coöperation can be established between the machinery already in existence in this city to combat this disease and employers of labor.

The incorporation of a fully-qualified physician as a working member of every large firm for the examination of all persons before their acceptance as employees will tend to detect many cases of diseases in its curable stages and not only save the life of the person afflicted but time and expense to the employer. Where it is possible the physician should be paid by and be responsible to the firm and should have a predominant voice as to whether a prospective employee is physically fit for his work or not. Where it is impossible for a concern to meet the expense entailed by retaining their own physician, the public clinics of the city should be utilized to a very much larger extent than at present and a certificate of health should always accompany that of good character, when a man is accepted for a position. Some such plan is at the present time in use in such concerns as The International Harvester Co., and Sears Roebuck

Co. of Chicago, and some other firms. Its general adoption will pay a hundred fold in greater efficiency and in lessened loss of time from sickness among employees and result in increased public support and confidence in those Houses thus actuated by a sense of their responsibility in matters of public health.

V.

DANGERS FROM SYPHILIS.

BY ABNER POST, M.D., BOSTON.

SYPHILIS is a communicable disease. In its communication, it is necessary that some appreciable discharge from an open sore of a syphilitic should be placed on either mucous membrane or some portion of the skin which is capable of absorption by a non-syphilitic person. At that spot, the inoculation takes place. There after an interval of some three or four weeks, the first manifestation of the disease in what is known as a primary sore, or chancre, is seen. Some six or seven weeks later occur what are known as secondary symptoms, which show that the disease is thoroughly a constitutional, and not a local one. Prominent among these symptoms are ulcerations about the mucous membranes, especially the mouth. It is only from these open sores that the communication of the disease can take place, so that patients with a primary sore, or with the ulcerations of the early secondary manifestations in the mouth, are practically the only patients who are really dangerous. Babies with hereditary syphilis might be included. Syphilis has the peculiarity of being transmitted to the offspring, and babies with hereditary disease are very subject to ulcerations in the mouth, which are capable of conveying the disease in exactly the same way as in the acquired disease of adults.

The microscopic entity, the bacterium of syphilis, is a very minute organism known as the spirocheta pallida, or better, *treponema pallidum*. It can be seen under proper microscopic conditions as a living entity, and its motions can be watched and studied. It is necessary for the understanding of the extent of the danger of communication, to realize that on the microscopic slide, where it is watched, this little entity loses its life, and can no longer be resuscitated, somewhere within an hour. In the pathological laboratory, when all possible pains are taken to preserve the life of the spirocheta, it is with difficulty that it is kept alive more than twenty-four hours. So we may see that the danger of transmission of syphilis is one that is confined to a limited number of syphilitics, and to a very short time after the material which contains the germ of the disease is separated from its parent body. We have, then, in its relation to food, in the first place, this certainty. It cannot be packed with food products and afford danger

weeks or months later, when the package is opened. It is hardly possible that the germ could be contained in any cooking material which is first prepared at home, and served hours afterwards. It is hardly to be conceived that an ingenious cook could accidentally hit upon means of preserving this spirocheta, which have so far escaped the pathologist. Cases of syphilis, then, which are communicated by food, must show themselves, in the first place, somewhere in the region of the mouth or the face, at some spot where the material has first been brought in contact with the individual who partakes of it.

Of the total number of primary lesions of syphilis which are recognized as such, some ten per cent. are found on parts of the body which are uncovered by the clothing, and of these a certain number occur on the hands, and such inoculations on the hands and fingers are practically confined to those who have dealings with the sick,—physicians and nurses.

The rest of these lesions are almost all entirely in the mouth, lips, tongue, tonsils, or somewhere in their immediate vicinity. Of these inoculations about the mouth, a certain number are known to be the result of immediate contact of the syphilitic with the healthy individual, in kissing. A certain other number of such inoculations take place from the common use of a pipe. We all know how common it is for people working side by side, to pick up the pipe that was laid down on a bench in their immediate vicinity.

But, subtracting these obvious methods, there still remain a certain number of cases of syphilitic inoculation about the lips or the mouth, which can best be explained through the use of utensils which convey food. In the first place, the most common medium for the conveyance of syphilis is, I believe, the common drinking cup. Statistics on the exact method by which inoculation takes place are practically impossible, but if one takes a series of individuals who show syphilitic chancres on the lips or the tongue, one finds that a large portion of them are individuals who come in contact with a large number of persons who use a common drinking utensil. It is not always easy to trace such things, but occasionally one gets such a story as that of a young lady with a chancre on her lip, who could point back to a time when she was shut in with a large number of excursionists in a small railway station on a hot day in July. There was a single glass for drinking water, and overcome at last by heat and thirst, she, with some repugnance, drank from this glass. As far as one could trace back the time of inoculation, her chancre on the lip dated from that moment.

Some time ago a lady with a chancre on the lip explained that she believed she had received her inoculation in her own kitchen. She had been in the habit of working at culinary concoctions in company with her servant maid. They tasted and altered the material which they hoped to cook, and tested it by tasting, using a

common spoon; first the mistress, then the maid; then the mistress again. The mistress discovered, after this habit had been exercised a number of times, that the servant girl in the kitchen had sores in her mouth which the mistress believed to be syphilitic. The girl was immediately discharged, to find a place in somebody else's kitchen, so it was impossible to confirm the mistress's story of syphilitic lesions of the girl's mouth.

There are other inoculations of the same sort which are not so easily traced, but about which one can often draw the inference that they come from eating in a cheap, crowded and perhaps unclean eating house. One case comes to my mind of a woman with an inoculation somewhere within the mouth, about the gums, which had troubled her dentist and her physician, and after a series of weeks, she showed a general outbreak of syphilis, which could be traced back to a certain time in the summer when she spent a fortnight in a crowded boarding house at the seashore. Her vacation had been spent in a boarding house frequented by people of various sorts, and some one among them had evidently inoculated her with syphilis, perhaps through the failure to cleanse spoons, and forks and glasses, but at any rate, that was the time at which her inoculation took place.

I took particular pains to mention babies with inherited syphilis as having the lesions capable of conveying disease, and I did this because it is so very common with nurse girls and those in the care of infants to test the nursing bottle in their own mouths before putting it into the baby's, and afterwards, when the baby drops it, to repeat the same operation. The same thing is done with spoons when the baby is fed with a spoon. In this way, there are occasional inoculations which take place from a syphilitic nurse girl to a healthy baby, or from a syphilitic baby to a previously healthy nurse. The danger, then, you can see, comes from persons with whom one comes into pretty close contact at the time when they themselves are dangerous. When I speak of boarding houses and the danger in such places of inoculation, which I feel sure exists, I want to say that while such danger comes undoubtedly from syphilitic waiters and waitresses, the danger also exists, and is perhaps fully as great from unclean guests, who are themselves careless, and the utensils which they have used and which have not been properly cleansed.

One cannot speak of such dangers without in the first place wondering a little bit as to their number, and next, as to how one is to avoid them. The number of such inoculations is certainly not very great, but it is sufficiently large so that we have them always with us. It is possible, at any moment, to produce cases for purposes of instruction. They are preventable. In the first place, the common drinking cup should go. Fortunately, it has already disappeared in many localities, but it is still to be found in a good

many workshops. It is a matter of some difficulty to make sure that proper means, by separate cups or the cleanliness of a cup which has been used, is provided.

We have means of controlling the spread of syphilis. Our modern methods, by salvarsan, or 606, allow us, not to cure the individual with such certainty as we hoped a few years ago, but its use controls the external and dangerous manifestations of the disease. So that one may find the treponema on the surface sores at one moment, and within a few hours after the administration of salvarsan, such treponema can no longer be found, and it is perhaps the most wonderful thing of all that this is practically the only disease against which the community fails to guard itself. We have been so long taught that syphilis carries with it a disgrace; that it is the fault of the individual, that it is very hard indeed for us to learn that at least 50% of our cases, if we include all the innocent infections and the inherited cases, are of innocent origin, and it is very necessary for us to know that while the cases of infection through food are not as many as those of some other diseases that have been mentioned, they are certainly too numerous to be allowed to go on without attempt on our part to prevent them. What is being done to limit the spread of the disease? The attempts to control it are individual rather than official. A free dose of salvarsan for the syphilitic patient is one of the most difficult of all remedies to obtain. I think I am right in saying that the only effort made by the State authorities to deal with the matter consists in the commitment to the State Hospital at Tewksbury and treatment there. I think we have a right, and it is our duty to ourselves and our suffering brothers and sisters and to the community, to demand that syphilitic patients be provided with proper medical treatment just as much as patients with typhoid or tuberculosis.

VI.

SUGGESTIONS IN THE EMPLOYMENT OF LABOR.

By T. K. CORY, BOSTON.

As stated by the Chairman, we hire a great many people. We have on our regular pay roll about 2250 people, in the store proper. In order to keep that number up, we must employ about 3500 to 4000 people a year. They leave because of moving out of town, better positions offered, and a great number of them because they get married. I am not recommending that so that you will come to the department stores for employment, but we lose a great many people through getting married. So it would be almost impossible to require a physical examination of that number of people. However, in our application blank we ask the question about their health in several ways. Then after they are in our em-

ploy, they are turned over to the medical department we have in the store, that handles from 150 to 200 people a day. We have taught the people that the best thing to do is not to wait until anything happens, but to use what we call the clinic, and use it freely, in order to prevent anything from happening. A little while ago I was up in the clinic, and a young fellow had lost a finger; caught it in the elevator machinery, and pulled the finger off. I watched them dress that finger, and a few minutes afterward one of the girls came up stairs, and I said, "What's the matter with you?" She said, "Why, I don't know; I got a pin scratch somewhere, and I guess this is it." That was more important than the fellow that lost the finger. We expected him to go to the clinic, but the fact that we can train our people to go there for pin pricks that are so small that she had to stop to find it, is of great importance, I think.—what our professional men here are trying to have people do.

We also have, in the store, shower baths for people that work where it is warm, or where they are exposed more or less, and the free use of soap. I believe soap is about the only thing we do use now that really proves we are civilized. We have in our shop a health committee. We have three nurses. One nurse is a visiting nurse, and she does an immense amount of good, because she tells your home conditions.

We send all our people to Rutland, or to some of the camps, when we first discover tuberculosis. That we pay for. We allow them their expenses, and in some cases a little bit more than their expenses. We have at the present time, I think, about six or seven cases that we are looking out for, of that kind. We have never yet allowed a case to get beyond the Rutland point before it was discovered. That means that they will accept them in Rutland if there is a fairly good chance of their getting well. We have several in the store today who have graduated and are back, and who have married and are raising families, who, as far as we know, are perfectly cured. We have two girls who have just come back. One of them had tubercular glands, and the other one had trouble with the lungs.

Now, someone, in speaking here, used the expression that if the stores, if the shops and the factories did not do these things because of philanthropy, that they ought to be done because of good business. I am not going to say that we are doing this for philanthropy or good business. However, it is splendid business. I can't understand why business men who have problems to solve and who are in the habit of solving problems, can allow their human machines to be as run-down and to be given as little care as they give in the average shop and the average factory. There seems to be a penalty for being a human being. Any business man or any manufacturer will take his machinery and will see that it has the best of belts, that the gears are

right, that it is lubricated with the very best oil, and the part of that machine—the only part that he cannot build—the machine with brains, because it is a human being, he allows to run down until he can't get efficiency out of the machine, or the person who is trying to run it. I should think that, if nothing else, would teach the business man that the proper thing to do is to look out for his help, and look out for his people. Now, my friend, Henry Abrahams, is going to follow me, and I know he is going to say something about how a person has got to live. They have got to live, and labor must be protected by the employer, and it is his right and his duty to protect that labor. What I mean by that is this: Unless a man can commence his reform in his own establishment it is a piece of impertinence for him to go out to reform the community until he has done the right thing at home.

I spoke a while ago when I had more than ten minutes, to a lot of business men who were reforming the city of Worcester, and I know that if they were going to hand to Worcester the kind of reform that they had in their own establishments, then I would say, "God help Worcester!" I believe that every business man, as a good citizen, has the right and the duty to protect his employees, to make them well and to make them happy, from two standpoints; first, because it is good business, and second, because it is philanthropy.

If you should ask me to sum up whether we have a successful business or not, I should say that the night before Christmas, as we stood on our first floor, a lot of well, happy people went out and wished us a Merry Christmas and a Happy New Year. I was standing talking to Mr. Edward Filene and he said, "Has the year been successful?" I said, "Yes. Our people are going out of here tonight happy, and they wish us well, and we have done our duty. If we have made money, that does not count so much. The thing that really counts is that the people are well and happy, and they wish us, as I wish you all, well."

DR. OTIS. It gives me great pleasure to introduce Mr. Henry Abrahams, Secretary of the Labor Union.

VII.

SUGGESTIONS IN THE EMPLOYMENT OF LABOR.

BY HENRY ABRAHAMS,

Secretary Central Labor Union.

I want to say amen to all that the doctors have been saying in relation to the handling of food. But in all large assemblies such as this there is always someone who perhaps strikes a discordant note, and I am going to be that one, I suppose. I want to say if all our employers were like Mr. Cory, perhaps the world would be a great deal

better. In one of the circulars on the table here today I saw that it was necessary not to over-work, also to keep clean. It costs money to keep clean; some people don't think that. I believe in a fair day's work for a fair day's pay, but I don't believe in that kind of a day's work from which a man goes home to his family and says, "Never mind, I don't care about any supper. I am tired; I guess I'll go to bed." I don't care about that kind of a day's work; a man exhausts too much physical energy.

Our physicians have said a great deal, and they are entitled to a great deal of credit for what the medical fraternity is doing to prevent disease. It is a question in my mind if they have got right down to the cause of the disease. They understand the effect all right, and I believe that a great many of them know the cause, but somehow or other, nobody says anything about it. You wouldn't expect a man, a married man having three children, a family of 5, who was getting \$1.75 or \$2 a day to live under the very best conditions. It is all very well for a number of social workers, perhaps, or a number of philanthropists to tell that man, "You ought to be clean; you ought to do this, and you ought to do that," but if you want to do away with tuberculosis, in my humble opinion, one of the ways, and one of the best ways, is to raise the standard of living. It is all very well to say, "Eat good food and plenty of it," but the man has got to get a living wage. (I learned that in Filene's.) In order to get good food, and plenty of it, he has got to have a living wage. There is no question about that. You can tell a man that he ought to dress warmly, and all that sort of thing, but he has got to have money to do it.

You tell a man his children ought to be well clad. So they ought. You can tell a man that everything about his home ought to be in a sanitary condition. That's true. There isn't any question about it; but he has got to have the wages, for the money he gets Saturday night determines where and how he shall live. Don't forget that part of it. That is why I am a trade unionist. I believe that I can help to prevent tuberculosis by seeing that a man is better housed. That's the question that should interest the community. The worker should be well housed; sanitary conditions should be as good at home as they are in the factory or in the shop. Conditions in the factory today are a great deal better than when I was a boy. I don't want to describe the conditions that existed in the various industries when I was a boy, a good many years ago, but they are better today.

Let me say, perhaps a great deal of what has been said here today ought to be taught in the schools. Perhaps, as has been suggested by one of the speakers, it would be a good idea for the doctors to visit the labor unions once again. Sometimes you forget that we are over 80% of the population. You don't seem to remember that, and you don't seem to remember that our

doors are always open. We are not a secret organization, but are always willing to hear of something that will do something more for the community. We are always willing to work with you. Let me assure the medical fraternity of Massachusetts, the medical association, if they will do what they did once before, send a number of doctors around to visit the various labor organizations, we will guarantee them a hearing and we will do what we can to help them.

EDWARD O. OTIS, M.D. I would say, in summing up what we have heard from others, that the main emphasis in the discussion seems to be upon the education of the public in general hygiene and cleanliness, dwelt upon by Dr. McLaughlin and Dr. Linenthal and others. Dr. Linenthal also suggests that a committee might be appointed to draw up a set of regulations for places where food is prepared and handled; those regulations should be followed by those who employ cooks, handlers and servers of food. These seem to be the main points that were emphasized, education of the people in proper hygiene, and cleanliness, and in the examination of those who handle food, cook food, serve food, or assist in cooking food.

This conference, of course, did not intend to draw up any definite rules to present, but simply, and its object I think has been accomplished, to consider the whole subject of the matter of preparing food, having it cleanly, and having it prepared by those who are not infected with various diseases. It seems to be self-evident that so long as both acute and chronic diseases are so prevalent, particularly tuberculosis, typhoid fever, and so on, that those who are serving food to the general public should in some way be examined and certified, that they are not suffering from either acute or chronic diseases, so that those partaking of food in restaurants and hotels shall be safeguarded. If this conference has simply set us to thinking about this matter it has accomplished its purpose.

In behalf of the conference I wish to thank those who have been kind enough to give us their attention.

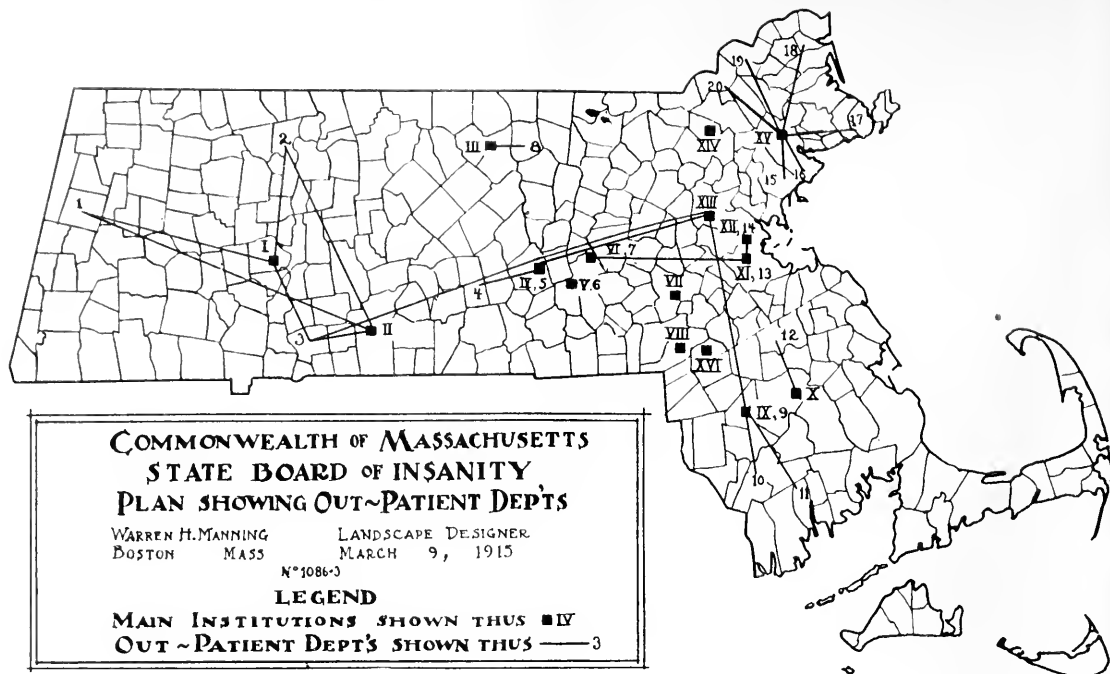

(The meeting was then adjourned.)

NOTE ON RECENT EXTENSION OF OUTPATIENT WORK IN MASSACHUSETTS HOSPITALS FOR THE INSANE.*

By A. WARREN STEARNS, M.D., BOSTON.

ONCE more Massachusetts has taken the lead in forwarding the scientific and human care of the

* Being State Board of Insanity Contributions, No. 40 (1915.9). (Bibliographical Note.—The previous State Board of Insanity Contribution (1915.8) was by E. E. Southard, entitled "On the Direction of Research as to the Analysis of Cortical Stigmata and Focal Lesions in Certain Psychoses," published in the *Transactions of the Association of American Physicians for the Year 1914*.)

mentally ill. That the care of such patients is part of the duty of the state has been recognized for more than eighty years, and eleven years ago Massachusetts took upon herself the work of maintaining and treating all dependent insane. The Massachusetts School for the Feeble-Minded has conducted a clinic once a week for more than twenty-five years, but till recently, this has been the only activity of any hospital staff outside the walls of its own buildings. Since 1885 the Massachusetts Board of Insanity has maintained a family-care service, during which time 1242 patients have been boarded out in homes. Still more recently several hospitals have taken up this work, and some have done a considerable amount of after-care and social service work. On Jan. 1, 1913, the Psychopathic Hospital in Boston opened the first full-fledged out-patient department to be conducted by any hospital for the insane in this state. Success was immediate, over 1000 new patients visiting the clinic during the first year, and active social service and after-care was begun.¹ In August, 1914, the Board of Insanity determined to make this work state wide, and each hospital was asked to arrange for an out-patient department as such. The work of these departments was divided, roughly, into four parts, namely, the clinic, after-care, family care, and mental hygiene. Most important, perhaps, are the clinics.² Because of varying conditions, each hospital was left to its own resources in formulating a plan for this work. All that was desired was that a clinic should be convenient for each large city. Where a hospital is in a large city, the clinics are held at the hospital itself, others are held at general hospitals or public buildings in neighboring cities. These clinics are conducted

by members of the staff of the nearest hospital. Some hospitals conduct but one clinic, while one conducts as many as six. They vary in frequency, from one which is daily (Psychopathic Hospital) to several which are monthly. Doctors in the community are notified of the dates of such clinics and are invited to send patients for consultation or treatment. Also, advice and treatment is given without charge to all cases of nervous or mental disease that apply, especial attention being given to former hospital patients. After-care and social service in the state hospitals are nearly synonymous, and more than ten institutions are doing this work to a greater or less extent. The clinics are of especial value in after-care, as patients find it more easy to report when near. As rapidly as possible the state family-care patients are being turned over to the hospital nearest their boarding place and the hospitals themselves are placing patients out rapidly. There is no doubt that all of this out-patient activity is the most practical sort of mental hygiene, but an additional effort is being made to interest the medical profession in the work of the hospitals, and many of the speakers for the Massachusetts Society for Mental Hygiene are in the state service. This vast movement is a two-edged sword, for important as it is to patients and community, it is of equal value in the socialization of the hospitals.

The accompanying map illustrates the work in a concise manner. The Roman numerals show approximate hospital locations and the plain numerals indicate clinics, the lines connecting each hospital with the clinics which it is conducting in whole or in part.

HOSPITALS.

- I. Northampton State Hospital. Clinics at Pittsfield (1), Greenfield (2), and Springfield (3).
- II. Monson State Hospital. Clinics at 1, 2, and 3, with Northampton.
- III. Gardner Colony. Clinics at Fitchburg (8).
- IV. Worcester State Hospital. Clinics at Spencer (4), and Worcester (5).
- V. Worcester State Asylum. Clinics at Worcester (6).
- VI. Westboro State Hospital. Clinics at Westboro (7), and Boston (13).
- VII. Medfield State Hospital. No clinic.
- VIII. Wrentham School. No clinic.
- IX. Taunton State Hospital. Clinics at Taunton (9), Fall River (10), and New Bedford (11).
- X. Bridgewater State Hospital. Clinic at Brockton (12).
- XI. Boston State Hospital. Clinic at Boston (Psychopathic Hospital) (14).
- XII. Psychopathic Hospital. Clinic at Boston (14). Dept. Boston State Hospital.
- XIII. Massachusetts School for the Feeble-Minded. Clinic at Waverley and also joint clinic at 3, 5, and 9 with Northampton, Worcester and Taunton resp.
- XIV. State Infirmary at Tewksbury. No clinic. It is hoped that one will be located at Lowell later.
- XV. Danvers State Hospital. Clinics at Lynn (15), Salem (16), Gloucester (17), Newburyport (18), Haverhill (19), and Lawrence (20).
- XVI. Foxboro State Hospital. No clinic.

Reports of Societies.

AMERICAN ASSOCIATION OF IMMUNOLOGISTS.

First Annual Meeting, held in Atlantic City, N. J., June 22, 1914.

The President, DR. GERALD B. WEBB, of Colorado Springs, Colorado, in the chair.

A Historical Sketch. DR. MARTIN J. SYNNOTT of Montclair, N. J., gave a brief account of the way in which the idea of this society had been conceived and of the manner in which its organization was effected. He stated that the idea had first occurred to him, in 1912, that a "Society of Vaccine Therapists" made up of men who had worked in the Praed Street Laboratories might prove mutually advantageous to the members. He had therefore written to the men in the United States and Canada who had taken the course in the Inoculation Department of St. Mary's, and later to those who had studied with Metchnikoff, Ehrlich, Wassermann, and in some of the other famous laboratories of Europe. Dr. Gerald B. Webb had suggested the more concise and inclusive title for the organization, "The American Association of Immunologists," thereby widening the scope of the society beyond the original conception of the speaker. A first attempt of organization was made in Washington in May, 1913, during the time of meeting of the Association

of American Physicians, but was not consummated until June 19, 1913, at Minneapolis, Minn., during the session of the American Association. They had now sixty charter members and eight applications for membership. The speaker predicted that they would in a few years be one of the most important medical organizations on this continent, and said he believed with Sir Almroth E. Wright that the physician of the future would be an immunologist.

The Production, through Immunization, of Specific Ferments against Bacteria; as Detected by the Abderhalden Test. MR. GEORGE H. SMITH of Glenolden, Pa., presented this paper which was based on the fact first demonstrated by Abderhalden in his pregnancy reaction, that specific proteolytic ferments were elaborated by the body in response to the parenteral introduction of foreign protein. The writer stated that they had proposed to test the limits of this specificity of ferment production by employing bacterial proteins. Rabbits received immunizing courses with *Staphylococcus aureus*, *Staphylococcus albus*, *Streptococcus*, *Pneumococcus*, *B. influenzae*, *M. catarrhalis*, and with a mixture of all. The substrates were prepared from the organisms by washing and drying heavy suspensions. The technic of Abderhalden was employed, using one and one-half c.c. of serum and ten mgrs. of the substrate. The results demonstrated that each serum was able to effect a marked degradation of the homologous substrate, while with the other substrates reactions were negative. Several slight non-specific reactions were obtained with *Streptococcus* and *Staphylococcus albus* substrates. It had been demonstrated that these were due to accidental infection. Sera from rabbits immunized with the mixture degraded all the substrates. The results indicated a relatively high degree of specificity in ferment production.

Professor E. C. L. MILLER of Richmond, Va., said that Mr. Smith had given a very good demonstration of the problem he had attempted to solve. From the biological standpoint it fitted in with and corroborated what they had been thinking for some time. It was obvious that a unicellular organism must of necessity form a ferment if it was to live. If the protein food materials outside the organism were insoluble, as they often were, they must be made soluble by digestion that they might diffuse into the organism. To accomplish this the unicellular organism separated from itself something that they had designated an enzyme, and this power of enzyme formation was one of the striking and essential characteristics of unicellular organisms. It was becoming clearer and clearer that a human body was made up of a mass of cells that were in many respects still unicellular creatures; Nature in working up from the unicellular to the multicellular had not so much produced a new kind of creature as a colony or interdependent community of unicellular forms, each one of which to a large extent retained its primitive functions. The function of reproduction was well shown in the process of repair. The function of motion was uncertain in even the unicellular forms. The function of enzyme formation was probably involved in all cell nutrition and could now be demonstrated in the laboratory by means of the Abderhalden reaction. That each cell maintained to a large extent an independent existence capable of motion, nutrition, reproduction, and response to stimulation had lately been demonstrated by the actual cultivation of tissue cells without the

body. All these factors worked together and tended to build up a view of the nature of our bodies that they had not held before. This work of Mr. Smith's showed clearly the specific nature of the ferments produced. He had seemed to show the cells as possessing an intelligence. They were presented with the problem "Devise and produce an enzyme to dissolve the bacteria injected." This was an entirely new problem and yet the cells responded with an enzyme so perfectly adapted to its functions that it would dissolve the substance in question and nothing else. By using such enzymes they often distinguished between substances otherwise indistinguishable.

Experience with Abderhalden Serum Diagnosis Reaction for Carcinoma. DR. OSCAR BERGHAUSEN of Cincinnati, Ohio, read this paper. He said that in their work the technique of Abderhalden had been followed for the most part, the only important deviation being that the serum was subjected to a preliminary dialysis before adding tissue. It was found that the serum of carcinomatous patients was most apt to digest tissues which corresponded most closely to the affected region of the patient. These results led to the conclusion that probably the embryonal origin was of some importance and according to this assumption those tissues that most probably represented the anatomic pathology of the case were selected. For the most part it was found that serum from a carcinoma patient digested tissue of the same origin as the affected tissue. Although serum usually digested only certain tissues, contrary results were occasionally obtained. The results of cases studied showed that with the exception of one case each of pregnancy, elephantiasis, empyema of the thorax, and tuberculosis of the spine, all control cases gave negative reactions. Serum from malignant cases digested some form of malignant tissue in every instance.

Abderhalden's Pregnancy Test. DR. WILLIAM WHITRIDGE WILLIAMS and DR. CLARENCE B. INGRAHAM of Denver, Col., presented this communication. After giving a brief explanation of the theoretical basis of the Abderhalden test, they stated that it had been applied to known and doubtful cases of pregnancy. Aside from the strict observance of the Abderhalden technic, the writers emphasized that the blood should be taken from a convenient vein under strict aseptic precautions with a dry needle kept in a sterile container. The serum should be allowed to clot spontaneously as centrifugalization frequently caused hemolysis. The serum should contain as few dialyzable substances as possible; it must be absolutely free from hemoglobin and from formed elements. If any of these conditions were disregarded, experience had shown that incorrect results were obtained. In the series of cases tested only two were of value differentially. One was a fibroid of the uterus and the other an ovarian cyst. Both gave negative reactions. The earliest case to give a positive reaction had missed menstruation only four days. Another case eleven days postpartum reacted positively. Observations of toxemic cases with albumin in the urine and increasing blood pressure, gave very slightly positive results with both the dialysis and optical methods. This confirmed the results obtained by Rubesamen in eclampsia cases. The test for pregnancy as worked out by Abderhalden might be considered a definite and reliable reaction.

Chronic Infections and Recovery without Immunity. DR. A. PARKER HITCHENS of Glenolden, Pa.,

read this paper. He stated that in the parenteral digestion of bacteria, the bacterial proteins were digested by the specific ferments in order that they might be eliminated from the tissues. This effect sometimes failed while the poisonous action of the other part was always manifested. This being the case the suggestion forced itself upon them that there was a physical basis underlying the action of these two parts. That was to say the action of the poisonous part never failed because it was diffusible and the tissue offered no barrier to it, while the non-poisonous part was not diffusible and under certain conditions the collection of cells in which it was located did not permit it to reach those cells capable of responding to its action. Accordingly, on the supposition that the molecule of the poisonous part was relatively small and that of the non-poisonous part relatively large they might divide infections into three classes: 1. Those in which the bacteria were surrounded by a firm wall of inflammatory tissue so dense and so perfect that antibacterial ferments were unable to penetrate the bacteria. The non-poisonous part liberated by autolysis or by ferments within the focus of infection did not escape through the capsule and the resistance of the host was not increased. 2. Those in which the zone of inflammatory tissue was less dense and less perfect. The non-poisonous part of the protein molecule could not penetrate the barrier of inflammatory tissue, but specific ferments formed as a result of vaccination or auto-inoculation might penetrate in sufficient quantity to give positive therapeutic results. The staphylococcus furuncle was an example of this class. 3. Those in which the infecting bacteria were not surrounded by a zone of inflammatory tissue which inhibited the activity of the non-poisonous part and the resultant newly formed ferments came in contact with the bacteria without hindrance. The self limited infections like typhoid fever were examples of this class. For obvious reasons infections belonging strictly to the first class could not be benefited by vaccine treatment. In the third class one might confidently expect much benefit from such treatment. Typical infections of the second class were no more difficult to treat than those of the third class. The diagnosis was made and the vaccine injected; as soon as the ferments had been produced in sufficient quantity, the infection was overcome and the patient recovered. Such simple technique was effective in relatively few diseases, but one must conclude that all other infections belonged to the first class; by far the great majority should be placed in the subvariety of the second class. Although they might react with little or no benefit to the mere injection of the vaccines, careful examination of other factors would reveal that with accessory methods of treatment positive results might be obtained.

PROFESSOR VICTOR C. VAUGHAN of Ann Arbor, Mich., said that he and Dr. Wheeler had hit upon a method of splitting up bacterial proteins to get the poisonous and the non-poisonous portion. The poison was not destroyed by alcoholic solutions of potash 1/10 to 2/10 of one percent. They had tried this and were able to split up colon, typhoid, and other pathogenic bacilli into poisonous and non-poisonous groups; they then tried the non-pathogenic organisms and found the same thing. The bacterium which produced the largest amount of protein poison was the *B. prodigiosus*. In round numbers it gave one hundred times as much poison per milligram as the anthrax bacillus. The conclusion

they reached from this was that the infectious character of anthrax was not due to the poison it liberated but to the capacity of the anthrax bacillus growing in the tissues. They tried animal proteins, serum albumin. They also found poison in vegetable proteins and as a matter of routine tested the non-poisonous parts and to their surprise these gave at least a certain degree of immunity to the living germ. They had split edestin, which many claimed was a pure protein body, and got the poisonous constituent out of it. They went over a great many proteins and made the statement, subject to revision after more extended research, that all proteins contained a poisonous group. Of all the papers on experimental work produced within the last few years there were only two which appeared to be contradictory to this theory, one by Auer and Van Slyke and one by Gibson, published in the *Philippine Journal of Science*. The work of White, Avery, and Wells seemed to point to the fact that the protein molecule did contain sensitizing groups. The Abderhalden test was a support to the theory of bacterial ferments and it was a biological law that when a living cell was stimulated by a foreign protein it tended to produce a ferment which digested that protein. If this were a law, further investigation might render protein sensitization of value in the prevention and treatment of disease. Every cell in the animal body must produce its own specific ferment, it could not receive and utilize its food in any other way. If one could educate the cell to produce a ferment which it had not produced, and he believed they did this with typhoid vaccination, the most reasonable explanation was that the body cells learned to digest typhoid bacilli. Dr. Vaughan said that he regarded the carcinomatous cell as a cell so modified that it produced specific ferments. The work done by J. W. Vaughan on cancer fitted in with this theory. He sensitized animals with cancer residue or the whole cancer cell. This led to an increase in the large mononuclear cells in which a ferment was found which when injected directly into cancerous tissue produced in the patient all the symptoms of anaphylactic shock. He had experimented with this ferment and was inclined to say at present that the poison in its purest form was not a protein, whether it was the histamine of Barger and Dale or some closely related substance, he did not know. He had made a great many experiments with the non-poisonous part of the tubercle bacillus and while he was not ready to publish his experiments, thought he might say that the non-poisonous part of the tubercle bacillus did not protect guinea pigs in any way from inoculation with tubercle bacilli. He thought it was harmful, for those treated died quicker than the others that were not so treated. In a great many guinea pigs, in the later stages of tuberculosis, he had injected the non-poisonous part and within one-half hour the temperature began to fall and continued to fall for two or three hours. This hastened the splitting of the tubercle bacilli. With rabbits the non-poisonous part apparently emphasized the resistance to the tubercle bacillus, but rabbits were irregular in their reaction toward the tubercle bacillus so they could not draw any conclusions. The non-poisonous portion of the tubercle bacillus was not harmful if given to rabbits intravenously.

Blood Platelets and Immunity. DR. GERALD B. WEBB of Colorado Springs, Col., presented this paper. He reviewed the history of blood platelets and showed that they probably contained or supplied

opsonin. Blood platelets were found to be increased by an altitude of 6000 feet, also by hyperemia of the marrow, and in carbon monoxide poisoning. Blood platelets were always increased in tuberculosis. The author found them increased in measles during the attack. They were found increased in pellagra. Preliminary experiments suggested the possibility that the blood platelets could sensitize tubercle bacilli.

The Influence of Vaccine Therapy on Blood Morphology. DR. FREDERICK E. SONDERN of New York City said that the cause of vaccine therapy might be furthered by observing the relation between the administration of vaccines and the leucocyte count, the differential count, and the exact degree of existing anemia. No work had yet been done with this point particularly in view. On those acute general infections in which vaccine therapy had been supposed to be of benefit, blood examinations had shown hyperleucocytosis with a decreased polymorphonucleosis. Even fatal cases showed a slight improvement in the blood picture with the use of vaccines. In reviewing the subject of vaccine therapy in acute general infections, it was necessary to state that while it had met with some success in practice, it was still open to question from a theoretical standpoint and should be considered as purely experimental. Autogenous bacterial vaccines had proved of value in cases of localized chronic infection. These were now used without the determination of the opsonic index. Further investigation should be given to those cases in which vaccine therapy was not successful. The successful use of vaccine therapy in chronic local suppurative processes seemed to cause an increased leucocyte count, a decrease in the relative lymphocytosis, and improvement in the anemia. In cases aggravated by vaccine treatment the leucocyte count was lower than before treatment, the relative lymphocytosis is more marked, and the anemia increased. Further investigation was necessary to determine whether those blood changes were constant, and whether they might be taken as an index of the utility of vaccine therapy.

DR. WILLIAM EGBERT ROBERTSON of Philadelphia, Pa., said that he had been interested in the clinical phase of chills in typhoid fever. The chill seemed to have a beneficial effect and was usually followed by a lower temperature, going to normal in a few hours and gradually rising again. Usually convalescence occurred. In the course of typhoid fever there was a very distinct lowering of the polymorphonuclears with relatively greater increase in the lymphocytes. Giving the bacterins in large doses, when it was possible to make a clinical impression on the case, gave the same results, seeming to indicate that the cause of the chill was essentially acute bacteriolysis.

Vaccine in Relation to Mouth Infection. DR. JOSEPH HEAD of Philadelphia, Pa., read this paper, in which he contended that the treatment of mouth infections should include the removal of all infecting masses by local surgical treatment, and application of mouth washes, and a more or less extensive treatment with vaccines. As mouth washes a one per cent. solution of hydrogen peroxide made slightly alkaline, or sodium silico fluoride in aqueous solution of a strength of 0.61 per cent. might be recommended. Their effect, since they were not germicidal, might possibly be due to a sensitization of the bacteria, thus allowing a more effective action of the body ferments. In connection with local treatment the vaccines gave excellent results. A

stock vaccine was used containing the bacteria most frequently found in forty-two cases examined. The writer gave the technique for removing material from infected pockets for the preparation of an autogenous vaccine. The course of the treatment should be regulated with great care, according to the presence or absence of reaction. The blood count was of interest and might prove of value as a guide to dosage. The writer reported cases which showed the value of vaccine treatment in mouth infections.

Complement Fixation Tests in Infective Deforming Arthritis and Arthritis Deformans: DR. T. W. HASTINGS of New York City presented this communication in which he described the method by which the complement fixation test was applied to cases of infective deforming arthritis and arthritis deformans in order to determine, if possible, the etiological factor of the disease. The antigens used included various strains of streptococci, other organisms isolated from cases of arthritis, and polyvalent gonococcus antigens. A Wassermann test was made in every case. Of 43 cases of arthritis, 25 of deforming arthritis have positive complement fixation and positive Wassermann tests; 19 cases of arthritis deformans gave positive tests, 17 reacting positively to streptococcus viridans, and four to a polyvalent gonococcus antigen. The 26 control cases, not arthritis, were with very few exceptions negative to complement fixation tests for streptococcus viridans. The results indicated that the streptococcus viridans was the probably causative agent in many cases of arthritis deformans. About 40% of cases of arthritis deformans should be considered as chronic infective deforming arthritis. The clinical manifestations of this condition were rarely due to gonococcus infections. When a positive reaction occurred with both a streptococcus and a gonococcus antigen, the reaction to the former should be considered the indicator of the causative agent, as there was often a latent infection with the latter in the genito-urinary tract.

Comparative Wassermann, Cobra, and Globulin Tests in Syphilis, with Report of One Hundred and Five Cases. DR. WILLARD J. STONE of Toledo, Ohio, presented this paper. He outlined in detail the technique of the cobra venom test and of Noguchi's butyric acid test for increased globulin, and stated that the comparative work upon the Wassermann and cobra venom reactions in syphilis had given very similar results. Of 105 cases examined by the author there was marked uniformity in these tests. There were some differences in outcome, but the discrepancies were not great. The result of the globulin test differed from the other two reactions in a larger percentage of cases.

DR. JOHN A. KOLMER of Philadelphia, Pa., said that in a certain percentage of cases the cobra venom test was slightly more delicate than the Wassermann reaction, but not when active serum was used. They had been using antigens reinforced by the addition of pure cholesterol for the Wassermann reaction and had not been able to convince themselves that the cobra venom test was as delicate as the Wassermann test thus reinforced. Cholesterol antigens were possibly hypersusceptible and required close controls. Since using cholesterol antigen they had found correct positive results in tertiary syphilis in a larger percentage of cases than with the venom test, though he believed that the venom test did have a distinct value in the diagnosis of lues in certain stages. In the primary

stage hypersensitiveness of the red blood cells rendered the venom test of little value in the diagnosis of syphilis.

DR. RICHARD WEIL of New York City said that the observations of Kobar showed that, in addition to the production of antihemolysis when venom was injected into animals, there was also a change in the red blood cells. He had tested a considerable number of hemolysins in order to see whether under any other conditions similar resistance developed on the part of body cells. It was found that the red blood cells of luetic individuals showed an increased resistance to cobra venom. In regard to the constancy of this fact on which its value as a diagnostic measure depended, they had not made a sufficient number of tests to show anything definite. Others seemed to have established the fact that it was fairly characteristic. While under given conditions the speaker believed that the cobra venom test might not compare equally with the Wassermann reaction, it would in a number of cases show positive results in luetic cases in which the Wassermann would be negative. It was certainly true that the Wassermann showed a considerably larger percentage in the total of positives.

DR. JOHN A. KOLMER of Philadelphia, Pa., said that he also wished to make the point that the protein reaction in cerebrospinal fluid also fell far short of the Wassermann reaction in the diagnosis of syphilis of the cerebrospinal system. The globulin test was uniformly positive in various types of inflammation of the spinal meninges. Hence they used the globulin test to differentiate tuberculous meningitis from the so-called serous meningitis or meningismus. In the latter the protein reaction was uniformly negative, whereas in tuberculous meningitis it was uniformly positive.

A Note on the Preparation of Bacterial Vaccines. DR. WILLARD J. STONE of Toledo, Ohio, read this paper. He stated that some of the reactions following the administration of bacterial vaccines were due to the presence of extraneous proteins, derived either from the culture media or the soluble excretory products of the bacteria. To do away with extraneous proteins all bacterial suspensions used in the preparation of vaccines, with the exception of such fragile organisms as the gonococcus and pneumococcus, were washed with a high speed centrifuge until the supernatant salt solution no longer gave the biuret reaction. In standardizing the vaccines a suspension of living washed organisms was used and Dr. Spooner's method of counting employed.

DR. A. PARKER HITCHENS of Glenolden, Pa., said that the effect of pepto-toxins present in bacterial vaccines was relatively slight because the quantity was very small. When injecting large animals for the preparation of antibacterial sera, enormous doses of the germs were administered and in such cases they saw the possibilities of pepto-toxin. Formerly when it was the practice to inject unwashed bacteria they were compelled to use as a maximum dose a quantity less than 1/1000 the amount that they could now use; since they washed the bacteria even with very large doses, symptoms of anaphylaxis were not observed.

DR. JOHN REICHEL of Glenolden, Pa., related that in attempting to immunize cattle against contagious abortion with suspensions of dead bacilli of contagious abortion they had observed that when unwashed bacilli were injected intravenously, severe and unusual symptoms followed almost immediately.

It was subsequently shown that these symptoms were due to peptotoxin. They had also precipitated peptotoxin with absolute alcohol, and it was shown that the substance remained unchanged after boiling, and that it could be kept almost indefinitely.

DR. JOHN A. KOLMER of Philadelphia, Pa., said that it had been their custom to wash vaccines grown on ascitic agar or blood agar, but not those that were made with organisms that would grow on ordinary nutrient agar. Dr. Kolmer also emphasized the necessity, in counting the bacteria with a counting chamber, of carefully filtering the dye before it was put into the chamber.

DR. WILLARD J. STONE of Toledo, Ohio, said it was necessary to wash all bacterial suspensions grown upon nutrient agar. They had found that such suspensions would give a very marked biuret test after centrifugation. All agar-grown bacteria in salt solution suspensions would give nearly as strong a biuret test at suspensions of bacteria grown upon serum or in bouillon.

Autoserotherapy, also the Therapeutic use of Inactivated Pus and the Value of Tuberculins in Serous Cavities. DR. WILLIAM EGBERT ROBERTSON of Philadelphia, Pa., read this paper in which he gave an extensive review of the work in autoserotherapy from the time of its introduction to the present. As applied to pleural effusions of the serous or serofibrinous type it had proven of value in proportion to the incipency of the tuberculous lesion. The injection of old tuberculin following the fractional withdrawal of fluids from the pleural cavity had given excellent results, especially in cases of long standing. Similar use of bacillary emulsion had proven less satisfactory. The reinjection of inactivated purulent exudates possessed some therapeutic value, although in general the results had not been uniform. Though inactivation destroyed the infectivity of the exudate, it was not necessarily sterile, so that it might possess the properties of a bacterin and also of a leucocyte extract.

DR. G. MORTON ILLMAN of Philadelphia, Pa., said he had had the opportunity of seeing many of these cases Dr. Robertson had reported from the clinical standpoint, and had been struck with the marked regularity of the results. There was through the entire series much that was encouraging in their bacterin work. In the very beginning of their work with bacterial vaccines in America they had issued a warning against the promiscuous use of bacterins and other toxic products and they were beginning to recognize that the things they had feared from the toxic effects of bacterins were coming to pass. Throughout this meeting thus far one thing stood out clearly and that was that the cellular living tissues did react to the call for the production of digestive ferments to any one of a dozen active infectious agents or their products. He believed Dr. Vaughan's hypothesis was a reasonable fact.

The Experimental Basis of Tuberculin Therapy. DR. GEORGE BURTON GILBERT of Colorado Springs, Col., presented this paper in which he reviewed the work done with tuberculin and stated that it was evident that a sound experimental basis for the use of tuberculin had not yet been found. The writer described his experiments with two series of guinea pigs and concluded that the results of the work indicated that the tuberculin treatment as given neither cured nor checked the course of the disease to any important extent.

Tuberculin Therapy: Its Present Imperfections and Future Improvements. DR. F. M. POTTENGER of Monrovia, Cal., read this paper. He declared that the fact that tuberculin had not succeeded in producing immunity was not an indication that it did not cause healing, for definite focal stimulation and healing had been seen to follow the administration of a tuberculin which had failed to produce a high degree of experimental immunity. Many of the faults ascribed to tuberculin were due to lack of skill in administration. Its value could not be estimated from the results obtained from its use upon experimental animals as the natural resistance of such animals was not comparable to that of human beings. Progress in tuberculin therapy depended upon an improvement in both the laboratory production and the clinical application. Work should be done in the laboratory in determining more exactly the constituents of the various tuberculins and in producing tuberculins of a definite standard.

DR. GERALD B. WEBB of Colorado Springs, Col., said he did not think anyone could work in Wright's Clinic and not be impressed that tuberculin did some good. In tuberculin therapy it seemed that they had an instance in which it did not seem possible completely to prove the therapeutic value by animal experimentation.

DR. JOHN REICHEL of Glenolden, Pa., said that the Laboratory of the Pennsylvania State Livestock Sanitary Board was in possession of two cultures of tubercle bacilli, one of the human type without virulence for experimental animals, and another, a bovine culture, which was highly virulent for experimental animals and for cattle. Tuberculins prepared with each of the two strains proved equally satisfactory in the tuberculin test of infected cattle. This would tend to show that tuberculins were not likely to vary so far as virulence was concerned, since the reactions with each of the strains was equally strong.

DR. JACOB BRONFEN BRENNER of Pittsburgh, Pa., called attention to the fact that inherent properties of different cultures of tubercle bacilli might be responsible to a certain extent for discrepancies in the results obtained by different investigators, as it was well known that pathogenic organisms were very apt to change their biological properties when cultivated on artificial media. Indeed it seemed that the greater the difficulty with which the organism adapted itself to the artificial media, the more radical the changes it underwent when once cultivated. The reason for this seemed to be that in such cases the organism must markedly change its metabolism in the process of adaptation to the medium, if it was to become at all adapted. The tubercle bacilli seemed to be a striking exception to this rule as the oldest strains seemed to retain their pathogenicity. The speaker said he had been working with the tubercle bacilli cultivated by Professor Besredka and he entertained the hope that this new tuberculin might be very useful in diagnosis of tuberculosis as well as for treatment of the disease. In his diagnostic work he had obtained 98% of positive results in different cases of tuberculosis and only 8% of positive results among non-tuberculous subjects. It was quite apparent that in many ways the tubercle bacilli of Besredka had acquired distinct properties. It seems quite important that those who reported favorable on their experiments of tuberculin therapy should give as completely as possible the history of the tubercle

baeilli used and the minutest details of their preparation.

DR. F. M. POTTENGER of Monrovia, Cal., said that he wished to make his attitude toward the laboratory clear. He who studied the disease exclusively would fail and likewise he who devoted his attention entirely to the patient; but by recognizing that both must be treated the greatest success would be attained. There was quite a difference between experimental tuberculosis and tuberculosis as they knew it clinically. With reference to the treatment of tuberculosis with tuberculin, one of the most important principles to remember was that the administration of this remedy was an individual matter. A large dose for one patient and for one pathological condition was a small dose for another, and a dose might be exceedingly large if the patient had not been prepared for it, and yet be a small one when this tolerance had been established. Small doses given infrequently increased the patient's sensibility, while large doses given at the right time decreased hypersensitiveness and increased the patient's tolerance, but it must be remembered that large and small were purely relative matters.

Presidential Address. DR. GERALD B. WEBB of Colorado Springs, Col., made this address, taking as his subject, "The History of Immunity." After dwelling on the life and work of Jenner and Pasteur, the speaker said that they were naturally proud to have with them in this country the one who took the next step forward as an immunologist, Theobald Smith, who showed, in 1886, that immunity from hog cholera could be produced by the inoculation of bacterial products. In 1890 came the discoveries of Behring and Kitasato on tetanus and diphtheria, and their anti-toxins for these diseases which found ready acceptance with the profession. Koch, with his products of dead tubercle bacilli was the first to treat disease with what later became Wright's conception of vaccines. Disastrous results followed Koch's experiments, but it was otherwise with Wright who might undoubtedly be regarded as the founder of vaccine therapy. In his own words, "The fundamental principle of vaccine therapy, as I conceive it, is to exploit in the interest of the infected tissues the unexercised immunizing capacities of the uninfected tissues." After paying a fitting tribute to the work of Wright, the speaker said that after eight years' experience with vaccine therapy, and with the passing of the early enthusiasm, it was well to review briefly its present status. Ehrlich, fresh from his recent triumphs in immunology, expected that within the next five years advances in chemotherapy might lead to successful treatment of bacterial diseases in a manner similar to his cure of spirilla infections. Until the predicted discoveries might be made, Wright's vaccine treatment and the improvements which were rapidly developing seemed to be the best treatment at hand. Time had shown that the method was of undoubted value in infections due to many bacteria. On the whole they had to record more failures than successes. One could not but feel, however, that many of the failures must be due to the inability of the protective substance to reach the foci of infection. This had been especially urged by Wright and more recently by Hitchens. The brilliant work of Vaughan, the American pioneer in immunology, seemed destined to aid them greatly. The elimination of the toxic group of the protein molecule had already borne fruit, and the

gratifying results of Rosenow, in his employment of autolyzed products of the pneumococcus in pneumonia, seemed to affirm his theory. It was yet too early to know how much better would be the employment of sensitized bacterins, but the theory of their usage was sound. Drug houses were trying to influence the profession, by broadcast advertising this time, to use dangerous and uncertain remedies to be inoculated in bacterial infections. Members of the Wright school could not too severely condemn the wide-spread use of the so-called phylacogens. Dr. Webb then referred to the work of Flexner, Swift and Ellis, and, in conclusion said he largely agreed with Wright that the physician of the future would be an immunologist, and he would also add, a hygienist. The hygienist and the immunologist must work closely together and Pasteur's prophecy, that it was within the power of man to rid the world of infectious diseases, would be eventually fulfilled.

The Relation of Parenteral Digestion to Immunity. PROFESSOR VICTOR C. VAUGHAN of Ann Arbor, Mich., made this address in which he stated that cells were composed of protein and required protein for their metabolic processes. The protein molecule as such was of no value, that was, digestion must take place before absorption or utilization could occur. In enteral digestion the cleavage was normally complete. Toxic products were further degraded as fast as they were formed. In parenteral digestion an analogous cleavage occurred but the toxic products were carried throughout the organism before further splitting could convert them into simpler non-toxic fragments. All cells were provided with the necessary mechanism to insure a degree of cleavage. This power resided in the ferments elaborated by the cell. Not every cell could utilize the same fraction of the protein complex. Therefore a selective action was manifested, each type of cell producing a definite type of ferment capable of acting upon the material supplied in such a way that it could become incorporated into the cell body. This conclusion reached by reasoning had been demonstrated by experiment upon digestion in unicellular organisms, in bacteria, and in leucocytic digestion. As a defense against foreign protein, as, for instance, invading bacteria, cells elaborated two kinds of ferments, group and specific. The group ferments were normally present in the blood and tissues of all animals. They were, within limits, general proteolytic ferments, but differed in kind, in amount, and in efficiency. Specific ferments were called forth on direct response to the introduction of a foreign protein and were capable of degrading that protein only. The production and presence of these general and specific proteolytic ferments had a very important bearing upon the phenomena of immunity.

DR. JACOB BRONFEN BRENNER of Pittsburgh, Pa., said he would like to know whether a substance like tetanus toxin, for instance, was considered primarily toxic or simply so easily digested by ferments that the toxicity did not require any incubation period to show itself.

DR. VICTOR C. VAUGHAN of Ann Arbor, Mich., replied that of course the word "toxin" had taken on a specific meaning. Toxin was a substance which produced an antibody when injected into animals. It might be said that all toxins were poisons but not all poisons were toxins. The protein poison was not a toxin; it did not produce any

antibody. Whether the toxins were ferments or not, Dr. Vaughan said he could not say. If it could be proved that the toxins were ferments the whole subject would be cleared up. Abderhalden had shown by his optical method that the toxins did split up proteins. That was as far as they had gone. The most rational explanation was that when diphtheria toxin got into a child's body or when it was injected into a guinea pig it split up the protein of the body and set the protein poison free. It was the protein poison that killed. He did not say that this had been demonstrated, but toxins certainly were closely related to the ferments. They acted in very small amounts, in high dilution, and they were destroyed by high temperatures. The toxin would act in dilutions so great that they did not give the biuret test. That was a still further indication that it was a ferment. Dr. Vaughan said he had an antipathy to calling these ferments anti-bodies; one might as well call pepsin anti-meat, because it digested meat.

DR. JAMES W. JOBLING of Nashville, Tenn., said that Dr. Vaughan had left little to be said. Dr. Vaughan had first aroused his interest in this subject and caused Shrouse and himself to study the cleavage products of proteins when acted upon by the leucoprotease of human leucocytes. They were able to obtain toxic substances in this manner and by fractionating the products, they found that the toxins were present in the protease fraction. They were unable to say whether there were actually primary proteases, or merely substances which were carried down mechanically with this fraction, though the ease with which they might be made non-toxic by the further action of trypsin and leucoprotease indicated that they were primary proteases. They had been inquiring into the methods used by the body in preventing the formation of these toxic substances and had found that the antitryptic action of the serum was due to the unsaturated fatty acid radicals of the lipoids. These lipoids might be extracted by chloroform and when the chloroform extract was properly treated the antiferments might be obtained almost quantitatively. The serum treated with an excess of chloroform lost entirely its antitryptic action and it also lost its activity if treated with an oxidizing agent as iodine. Guinea pig serum from which the antiferment had been removed became toxic for other animals of the same species, and this applied to all sera which they had tested. In the course of their work they had observed that bacteria, kaolin, and other substances would remove the antiferments from the serum and render it toxic. This was important in view of the work done with the so-called anaphylotoxins, and also suggested the possibility of there being a true auto-intoxication due to local or generalized absorption of antitrypsin. It was also possible that some of the metabolic disturbances leading to cirrhosis of the organs, etc., might have their origin in a disturbed ferment.

When Dr. Vaughan stated "that live bacteria ingested proteins," did he mean that the bacteria took up and assimilated native proteins, or did he use the term in a more general sense and include the lower cleavage products?

DR. VICTOR C. VAUGHAN replied that he did not believe that any cell took a protein and absorbed it as a whole, but it might absorb it without splitting it far enough to liberate the poisonous group. He thought they could claim pretty good evidence that no cell could take a foreign protein and build it

directly into its body. Dr. Vaughan also discussed the relation between the antitrypsin and the trypsin of the blood. Here lay a most important field of investigation. The balance between the proteins present in the blood and the proteolytic ferments must be something which was capable of the nicest kind of adjustment. From what he had said one could readily see that while he believed that the ferments of the body destroyed the invading organism, life might be saved by an abundance of the antibody preventing the too rapid action of the substance which was destroying the bacteria.

Demonstration of a Simple Method of Making Cultures from Tissues, and Its Application in Arthritis Deformans. DR. EDWARD C. ROSENOW of Chicago, Ill., presented this paper in which he stated that up to the present time there had been no systematic bacteriological examination of the tissues of the body during infection. The author had devised an apparatus which was efficient for this purpose and which he described fully. In preparing cultures from tissue emulsions, it was advisable to plant the emulsion deep in rather tall tubes of aseptic dextrose agar. With this method of planting there were afforded all the gradations between aerobic and anaerobic conditions, and growth was obtained from organisms ordinarily hard to cultivate. The method described had proven particularly successful in cultivating cases of arthritis deformans. Streptococci, staphylococci, and organisms resembling *Bacillus mucosus* and *B. welcheii* had been isolated from 54 cases. Cultures made from the joint and also from the lymph gland draining the joint had frequently yielded the same organism. This fact would be of service in studying arthritis deformans. It would be of interest to discover how this micro-organism acted upon the body to produce this form of disease.

DR. VICTOR C. VAUGHAN of Ann Arbor, Mich., said he had followed Dr. Rosenow's work and believed it to be of the greatest importance scientifically and practically.

The Intraspinal Treatment of Syphilis of the Central Nervous System with Salvarsanized Serum of Standard Strength. DR. HANSON S. OGILVIE of New York City read this paper. He stated that in order to reach the diseased areas in syphilis of the central nervous system, intraspinal treatment as introduced by Swift and Ellis was strongly recommended. The author based his preparation of salvarsanized serum upon the method of Swift and Ellis, but he prepared his serum by adding salvarsan and subsequently heating *in vitro* so that the strength of the curative agent might be regulated. Thus he obtained a serum of known salvarsan content. With a carefully perfected technique of preparation and administration of the serum there was little danger of severe reaction. In fifty percent of the treatments there was no reaction of any kind beyond a slight temporary weakness. It was important that the dosage should be small—within 1.0 mg. The results of the cases studied demonstrated that the laboratory evidences of active syphilis, as shown by the Wassermann reaction, in both the blood and spinal fluid and the cell count and globulin content, were reduced to a greater or less degree in every instance. In the majority of cases there was marked clinical improvement. The method was of interest because it furnished the means of giving salvarsan in small doses intraspinally without danger to the patient.

Book Reviews.

Metabolism in the Exudative Diathesis. By ALBERT NIEMANN, M.D., Berlin. Bonn: Marcus and Webers. 1914.

This monograph presents the results of a clinical and laboratory experimental investigation on metabolism, based on a study of three children with supposed exudative diathesis. The author concludes that in every case there was a notable increase of heat formation and that in two the carbon dioxide production was exalted. He believes that the nature of the exudative diathesis rests on a disturbance of metabolism, which he has for the first time demonstrated. The work, which is chiefly of interest to experts, is illustrated by twenty-eight tables and five graphic charts. It is a typical piece of Teutonic investigation.

The Prophylaxis of Malaria, with Special Reference to the Military Service. By CHARLES F. CRAIG, M.D. Washington: Government Printing Office. 1914.

This bulletin (No. 6) from the office of the Surgeon-General of the War Department, presents an excellent laboratory and field study on the prevention of malaria by screening and by mosquito extermination. It is admirably illustrated with five charts, twelve full page plates and three figures in the text; and there is an excellent terminal bibliography of seventy titles. The work represents one of the important departments of activity of the army medical service and is a valuable contribution to the literature and knowledge of the subject.

Transactions of the National Association for the Study of Pellagra. Second Triennial Meeting, Columbia, S. C. The R. L. Bryan Company. 1914.

This belated volume records the proceedings of the second triennial meeting of the National Association for the Study of Pellagra in the fall of 1912. These consist of a series of papers by various international experts, conveniently grouped under headings of etiology, epidemiology, local history, diagnosis, laboratory investigations, clinical features, treatment and miscellaneous aspects. Not all the papers read at the meeting are here presented owing to interference with return of proof by the European War. There are several charts and maps illustrating the distribution of the disease in this country. The third triennial meeting of the Association is to be held next summer at a place not yet selected.

Public Health Laboratory Work. By HENRY R. KENWOOD. Third Edition. New York: Paul B. Hoeber. 1914.

The subject matter of this book is considerably more limited in its nature than the title would imply, since it deals almost exclusively with the chemical side of public health laboratory work. The bacteriological side of the subject is given but passing notice. An introductory note describes and gives directions for the use of chemical apparatus used in health laboratories.

The subjects considered are the examination of water, sewage, soil, air, food and disinfectants. The various processes are described in an exceptionally clear and concise manner, and are accompanied by sufficient theoretic discussion to make their use intelligible. It would be well if more distinction were made between the tests commonly used as a routine and those of less important or only occasional use. This work, like many of foreign authorship, is handicapped from the fact that many of the methods are not those usually employed in this country.

The Heart in Early Life. By G. A. SUTHERLAND, M.D., F.R.C.P., Senior Physician to the Hampstead and Northwest London Hospital, Physician to Paddington Green Children's Hospital. London: Henry Frowde and Hodder and Stoughton. 1914.

Dr. Sutherland in this admirable little book in the series of Oxford Medical Publications, emphasizes the importance of polygraph tracings in the diagnosis of cardiac conditions in childhood. He calls attention to the frequency of irregularities of the pulse in childhood, explains the various types and emphasizes the facts that they are not signs of heart disease and do not require treatment. He also calls attention to the frequency of murmurs "about the heart" in childhood and that they do not mean organic disease. He describes three types,—the pulmonary systolic, the cardio-pulmonary and the systolic murmur of cardiac debility. He calls especial attention to the frequency of subjective symptoms pointing to the heart in children, which are really manifestations of a neurasthenic state, and to the absence of subjective symptoms when there is disease of the heart. He notes the frequency and relative unimportance of acute dilatation of the heart in childhood. He attributes this to the fact that the tonicity of the heart muscle is not as well developed in childhood as in later life. The chapters on valvular murmurs and on treatment are remarkably good and full of common sense. The whole book shows that the author is thoroughly familiar with heart disease, and its peculiar manifestations in childhood. It will well repay everyone, whether a pediatrician or not, to read this little book most carefully.

THE BOSTON Medical and Surgical Journal

An independently owned Journal of Medicine and Surgery, published weekly, under the direction of the Editors and an Advisory Committee, by the BOSTON MEDICAL AND SURGICAL JOURNAL SOCIETY, INC.

THURSDAY, APRIL 15, 1915.

EDITORS.

ROBERT M. GREEN, M.D., *Editor-in-Chief.*
GEORGE G. SMITH, M.D., *Assistant Editor.*

WALTER L. BURRAGE, M.D. }
FREDERICK T. LORD, M.D. } *For the Massachusetts Medical Society.*

COMMITTEE OF CONSULTING EDITORS.

WALTER B. CANNON, M.D.	ALLAN J. McLAUGHLIN, M.D.
HARVEY CUSHING, M.D.	ROBERT B. OSGOOD, M.D.
DAVID L. EDSALL, M.D.	MILTON J. ROSENAU, M.D.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, or the United States. \$6.56 per year for all foreign countries being added to the Postal Union.

The editor will be in the editorial office daily, except Wednesday and Sunday, from twelve to one-thirty p. m.

Papers for publication and all other communications for the Editorial Department should be addressed to the Editor, 126 Massachusetts Ave., Boston. Notices and other material for the editorial pages must be received not later than noon on the Saturday preceding the date of publication. Orders for reprints must be returned in writing to the printer with the galley proof of papers. The Journal will furnish the first one hundred reprints for half the cost price.

All letters containing business communications, or referring to the publication, subscription, or advertising department of the Journal, should be addressed to

ERNEST GREGORY, *Manager.*

26 Massachusetts Ave., Corner Boylston St., Boston, Massachusetts.

TYPHOID FEVER IN THE CITIES AND TOWNS OF NEW YORK DURING THE LAST DECADE, AND DISINFECTION BY CHLORINATION OF PUBLIC WATER SUPPLIES IN THE STATE.

CONTAMINATED water being the chief of the many agencies by which typhoid is spread, improvement in the character of public water supplies naturally constitutes one of the most important factors in successfully combating the disease, and is a matter of vital interest in every community. In the latest issue of *Health News*, the monthly bulletin of the New York State Department of Health, there is presented a series of curves which show in graphic form, like the elevations and depressions of a temperature chart, the prevalence of typhoid fever in the cities and towns of over ten thousand inhabitants in the state, from 1904 to 1914, inclusive. From this showing it is seen that fifteen of the forty-five cities and smaller places have a record of typhoid rates almost uniformly below 20 per

100,000 for the whole period of eleven years, and it is found that in this, which may be called list of honor, are included all the first and second class cities, except Troy, and six cities of the third class. Eleven other of the communities have had generally satisfactory typhoid rates in recent years, but either high rates during the early part of the period in question or occasional epidemics during its course; and all but one show rates under 20 per 100,000 for the year 1914. In the case of Auburn, Elmira, Poughkeepsie, Rensselaer and Rome, which are on this list, and of Cohoes and Elmira, which are not charted like the rest, it is stated that the more recent decrease in the typhoid death-rate was definitely associated with improvements in the public water supply. The remaining seventeen cities and villages, among which Troy is included, show more or less consistently high typhoid rates; but, taking the year 1914 alone, Fulton, Kingston, Little Falls, Middletown, Plattsburg and Loekport should be removed from this last list, and in the case of Loekport the reduction in typhoid was directly due to chlorination of the public water supply. In this connection it is noted that Ithaca, Newburgh, North Tonawanda and Oswego have recently taken steps to have their supplies purified by the same method. In the year 1914 the six highest typhoid death-rates in the state were, 61 at North Tonawanda, 41 at Dunkirk, 34 at Troy and Corning, and 33 at Hudson and Watervliet, and in each one of these instances, with the possible exception of Troy, the public water supply is known to have been subject to serious contamination. In well-protected communities typhoid fever rates are now falling rapidly to 10 per 100,000, or below; so that if any city or town has a rate of 20, or over, there is urgent need that serious attention should be given to its water supply and other local sanitary conditions.

In the same issue of *Health News* is published a paper on the disinfection of public water supplies by chlorination, by Theodore Horton, director of the division of sanitary engineering in the State Health Department. He points out, that while the first practical demonstration of the value of hypochlorite of lime for disinfecting large volumes of water was made in England, almost simultaneously, investigations, which were being prosecuted at the Massachusetts Institute of Technology, attested the utility of this means of disinfection. The first public water supply in this country to be treated by the hypochlo-

rite was that of Jersey City, in 1908, and since then such disinfection has had a remarkable growth, so that today we find chlorination plants in very general use. He remarks, however, that, valuable as the discovery of this method has proved to be in the protection of human life, it is not to be regarded as a panacea for water supply troubles; nor is its practical application always a simple matter. On the contrary, there are some classes of waters which do not lend themselves readily to effective chlorine treatment, and in treating those which do, many difficulties have had to be overcome. In the past two years many improvements have been made in chlorination plants and processes, and the most important of these is the substitution of chlorine gas for hypochlorite of lime. When we consider that chlorine is just as effective as the latter, one can readily understand how, if the gas can be applied directly to the water, the method of treatment may be simplified. This has now been done, and there are upon the market a number of devices for applying chlorine gas which, while somewhat complex in their mechanical working, are durable in material and construction and quite positive in operation.

Up to the present time—and until its efficiency had been clearly demonstrated—the disinfection of water supplies by chlorine has been largely limited to the treatment of water which has first been passed through sand filters. Unfortunately, there are many supplies which are subject to continuous sewage contamination, and hence unsafe, where the municipalities or companies are financially unable at once to meet the expense of sand filter plants. When, therefore, one considers that the cost of a chlorination plant is only a very small fraction of that of such a filter plant, and that the cost of the minute quantity of chlorine required to disinfect the water is almost negligible, there would appear to be no plausible excuse now for any municipality or water company to furnish a community with unsafe water. It is not to be expected that a chlorination plant will make a roily, colored or otherwise physically objectionable water attractive, but, when properly installed and operated, it can be relied upon to destroy disease bacteria, and thus to safeguard the people against water-borne diseases and epidemics. In the state of New York at the present time practically all the larger and many of the smaller water filtration plants are equipped with chlorination apparatus for disinfecting the final effluents from the filters. In

addition to these there are many municipalities, including New York City and Buffalo and various smaller cities and towns, where the water supply is not filtered, but where a chlorination plant is installed and the water disinfected before use. In the paper are cited two striking examples of the efficacy of chlorine treatment for the protection of life and health, illustrating the value of this method in cases of emergency; the places referred to being the cities of Lockport and North Tonawanda, both of which take their water supply from the Niagara River a few miles below Buffalo, which pours its raw sewage into the river.

FEEBLE-MINDEDNESS IN MASSACHUSETTS.

THERE is at present pending before the Massachusetts General Court a bill providing for a third institution for the care of the feeble-minded in this Commonwealth. In this connection there is particular pertinence in a statement recently published relative to the number of feeble-minded in Massachusetts.

In 1912 the State Board of Insanity made a census through correspondence and field work, by means of which 5000 cases of feeble-mindedness were reported outside the state institutions. In 21 towns, however, in which more careful investigation was made, nearly three times as many cases had been found as had been reported through correspondence. On this basis it is estimated that there are probably from 10,000 to 14,000 in this state uncared for by any institution. Beside this approximate number of feeble-minded at large, there were in last October 2664 cases receiving institution care. The hospitals at Waverley and Wrentham are entirely inadequate to provide for so large a number of inmates. They are now accommodating over 8% more than their capacity, and there is a waiting list of 1310 cases for the two institutions. Moreover, a disproportionate number of cases are drawn from Eastern Massachusetts, while the western portion of the state contains relatively as large a number of those needing institution care.

The menace to the state and to local communities by such lack of adequate provision for care of the feeble-minded is obvious. Moreover, to leave these individuals at large makes it impossible to prevent their rapid increase in numbers.

The cost of maintaining the feeble-minded in institutions is far less than the loss involved by leaving them in their homes.

"Directly or indirectly the burden of support for the feeble-minded must devolve largely on the public. The problem is, therefore, where they can be taken care of with greatest advantage to themselves and the community. If they are permitted to remain at large they jeopardize the efficiency of our public schools and other agencies designed for the training of normal children and inevitably lower the moral tone of the community in which they live. They cannot be taught by ordinary methods. Special classes can handle relatively few of them and meet their needs only to a limited degree. Totally misunderstood by the average teacher, on whom their presence puts an unjust strain and anxiety, they are an idle and degrading element in the schools. The resulting truancy, delinquency, immorality, and crime entail a heavier expense on the state than would be required to provide adequate institutional care.

"On the other hand, most of the feeble-minded are capable of some industrial training and may become wholly or partially self-supporting. Thus from demoralizing and destructive agents a wise care and education will transform many into productive members of society. When this is accomplished it may even be possible for some to return to the community if they can be carefully safeguarded against the possibility of injury to themselves or others. But in any case institutional care is an imperative necessity during these years of preliminary training and during the dangerous periods of adolescence and early maturity.

"State schools especially planned and adapted to the needs of the feeble-minded afford the only means we have of dealing with this class which meets the demands of economy, efficiency, and justice. Ignoring, however, the injustice of a policy which treats the normal and the feeble-minded alike, economy alone requires that the feeble-minded be maintained in separate institutions rather than in the regular correctional schools of the state."

On the whole, segregation of the feeble-minded in state schools is an economy, grievous as the financial burden at the time may be. Statistics show that the state of Massachusetts is now employing 36% of all its revenue for charity, a total expenditure of \$6,839,093.59. Yet of all this only 9.4% was spent for the feeble-minded and 50% for those actually insane. This seems a disproportionate amount in view of the inadequacy of present provision for the feeble-minded and the seriousness of the menace which their presence at large in the community constitutes.

The above facts seem to present a conservative statement of the conditions relating to feeble-

mindedness in Massachusetts and therefore deserve serious consideration by physicians and by legislators with reference to the present bill now pending before the legislature. The statement closes with the following conclusions, which are herewith commended for consideration at this time.

"That the overcrowded conditions at Waverley and Wrentham, the long waiting list at both institutions, and the presence of 10,000 feeble-minded at large in the state, demand that more adequate provision be made for their care.

"That without such care this large class of defectives constitutes a grave social menace to the state and imposes a heavy economic drain on the public resources.

"That not only the most humane but the least costly way to handle these unfortunates is by affording them institutional care and protection, and industrial training.

"That there is, therefore, urgent need for the establishment of a third school for the feeble-minded easily accessible to the center of population in Western Massachusetts."

DENTAL REGISTRATION IN MASSACHUSETTS.

THERE is at present pending before the Massachusetts General Court a bill (Senate No. 228) regarding the registration of dentists in this Commonwealth. Only two other states besides Massachusetts now permit the registration of dentists who have received no diploma from a recognized dental school. The present bill aims to remedy this condition in Massachusetts by the provision that,

"Any person 21 years of age or over and of good moral character, who is a graduate of an accredited high school or presents proof of equivalent training and has received a diploma from the faculty of a reputable dental college as defined in this act, shall, upon fulfillment of requirements for applicants as hereinafter specified, be entitled to examination by the board of dental examiners."

The bill further allows the privilege of examination for registration for those who have spent three years at a dental school and who have passed all the examinations of the first two years, although they have not yet received a degree.

Further, the bill provides as a measure of preventive dentistry that any person of good moral character and twenty years of age may qualify

by examination as a dental hygienist and may be given a certificate, allowing him or her "to clean teeth under the direction of a registered dentist of this Commonwealth, in public or private schools or institutions approved by the local board of health."

The JOURNAL has previously advocated editorially the passage of this so-called dental nurse clause, and its incorporation with the legislation regarding the practice of dentistry in this state. The importance of prophylaxis in the prevention of dental caries and its extensive consequent effect on general physical health seem so great that we believe this measure, by making possible more thorough care of the teeth, especially among children, than can be accomplished without excessive expense by practicing dentists, would contribute materially to the advancement and maintenance of the public welfare.

EMPLOYMENT OF PATIENTS IN HOSPITALS FOR THE INSANE.

THE recently published bulletin (No. 7) of the Massachusetts State Board of Insanity for March, 1915, contains a striking statement of the number of patients employed in the various state institutions in different occupations and industries. This survey of occupations for a single day at each of the state institutions under the supervision of the board, shows, in tabulated form, the total number of patients at each hospital on that day, the number employed, those unable to be employed, and the number idle. Stated in percentages the total number of employed in the various institutions was as follows:

At Wrentham, 95%; Gardner, 92%; Monson, 83%; Medfield, 81%; Worcester, 78%; School for the Feeble-minded, 73%, Taunton, 71%, Westborough, 70%; Danvers, 61%; Boston, 60%; Foxborough, 54%; Northampton, 49%; Bridgewater, 42%; and Psychopathic Hospital, 30%. Further tables show the actual number of hours for which patients were employed in these institutions. The bulletin continues with an account of similar work being prosecuted in Illinois, and a statement of the manner in which these methods are followed in the hospitals of Germany and Switzerland. The account is extremely interesting in showing how completely this occupational side of therapeutics seems to be carried out in our state institutions.

MEETING FOR BELGIAN RED CROSS.

IN another column of this issue of the JOURNAL we publish a communication from Dr. Antoine Depage of Brussels to the American medical profession relative to the present urgent needs of the Belgian Red Cross.

Mme. Marie Depage, wife of Dr. Depage, head of the Belgian Red Cross, who has been sent to America to collect funds for the Belgian Red Cross relief work in the field hospitals and trenches, will speak at a meeting for the medical profession on April 14, at 4 o'clock, in the Boston Medical Library.

On the following day, April 15, at the same hour, Mme. Depage will speak at the house of Mrs. Edwin S. Webster, 261 Clarendon Street, Boston.

Invitations to these two occasions have been issued, and it is earnestly to be hoped that a liberal sum may be raised for this important measure of international medical relief.

MEDICAL NOTES.

GRIP STILL PREVALENT IN NEW YORK.—The mortality during the week just passed was noteworthy by reason of the very considerable increase in the number of deaths reported from all causes, the total having been 1831 as compared with 1612 in the corresponding week of 1914, an increase of 219 deaths. The increase in the death-rate was 1.39 of a point, which was equivalent to a relative increase in the number of deaths of 155.

The most potent factor of this increased mortality was the prevalence of influenza in a more virulent form than has happened in some years, with a corresponding increase in the deaths from acute respiratory diseases and organic diseases of the heart.

There were 407 deaths from acute bronchitis, broncho-pneumonia and lobar pneumonia, this number being in excess by 143 deaths of the number of deaths reported from this cause in 1914. In addition to this, the organic heart diseases showed an increase of 42 deaths. The mortality from the infectious diseases—measles, diphtheria, croup, and whooping cough—was slightly in excess of that of the previous year.

The prevalence of influenza made itself felt among persons of every age, but especially was the effect noticeable among the old people over 65 years of age, in which age group the number of deaths was increased by 541. Children under five years of age showed an increased mortality of 54 deaths, and between five and sixty-five years there was an increase of 111 deaths.

In spite of last week's high death-rate the death-rate for the first fourteen weeks of 1915

was only 14.38 per 1000 of the population, as against a rate of 15.57 during the corresponding period in the year 1914, a decrease of 1.19 of a point.

AWARD OF THE SEAMAN MEDAL.—It is announced that the Lewis Livingstone Seaman medal has been awarded to Dr. William C. Gorgas, Surgeon-General of the United States Army for progress and achievement in the promotion of hygiene and the mitigation of occupational disease.

PUBLIC HEALTH ORGANIZATION IN THE STATE OF NEW YORK.—The New York State Department of Health has recently issued as the first part of its thirty-fifth annual report, the report of the public health council. This council, consisting of Hermann M. Biggs, M.D., Chairman, and six other members, clearly sets forth the aims and the organization of its work from its creation in 1913 to December 31, 1914. The first action of the council was to prescribe the qualifications of the various divisions under which the public health law provided for the conduct of the affairs of the state department of health. These divisions were of tuberculosis, child hygiene and of vital statistics. The council next set about prescribing the qualifications of sanitary supervisors of sanitary districts and of the qualifications of public health nurses. The position of sanitary supervisor was voted to be placed under Civil Service rules and of the 141 persons taking the examination in March, 1914, 87 were placed on the eligible list.

The council further framed a sanitary code, the first chapters of which went into effect May 1, 1914. Chapter 1 deals with general provisions, chapter 2, communicable diseases, and the following five chapters cover milk and cream regulations, midwives, labor camps, nuisances and miscellaneous matters such as spitting, common drinking cup and barber shops. This report should be of great interest and value to those engaged in the service of the public health.

The second part of the annual report contains a letter from Dr. H. M. Biggs, as Commissioner of Health, to the Governor of New York, in which he makes an appeal for increased appropriations to carry forward the campaign of education, to extend laboratory facilities for the diagnosis and specific treatment of disease, to safeguard the people against preventable diseases and to postpone the approach of those diseases which are inevitable. He further states that the state department has set for itself the task of saving 25,000 lives within five years, pointing out the fact that in the census of 1913 the death rate of the State of New York was next to the highest, having a percentage of 15.2 per one thousand inhabitants.

NEW RED CROSS BUILDING.—On March 27 the corner stone of the new Red Cross building at Washington, D. C., was laid by President Wil-

son and Ex-president Taft with appropriate ceremonies.

“The new building faces the wide sweep of grounds back of the State Department and White House. The building and site, provided by Government appropriation and private subscription, will be turned over in perpetuity to the American Red Cross. Here the organization will make its permanent home, and the building will house all of the administrative officers in charge of Red Cross work. The commission has at its disposal \$800,000, of which \$400,000 was appropriated by Congress, on condition that the Red Cross raise an equal amount by private subscription. The additional sum was made up by the following subscriptions: James A. Serymsor, \$100,000; Mrs. Russell Sage, \$150,000; Mrs. Edward H. Harriman, \$50,000; the Rockefeller Foundation \$100,000.

“The new building, like most of the others in the stately group about it, will be of white marble and the general design of the structure, its façade, columns, etc., will be on classic lines. A parked terrace will raise the building above the street level, and wide marble steps will lead up to the entrance. A row of twelve Corinthian columns of white marble will stretch across the entire front of the structure, the capitals supporting the copper-finished roof. Two massive bronze entrance doors are one of the striking features of the architectural plans. Within the high-arched vestibule a flight of broad marble stairs will lead to the second and third floors. On the stairway landing a marble tablet will be placed bearing the following inscription:

“A memorial built by the Government of the United States and patriotic citizens to the women of the North and the women of the South held in loving memory by a now united country, and that their labors to mitigate the sufferings of the sick and wounded in war may be forever perpetuated, this memorial is dedicated to the service of the American Red Cross.”

“On the landing will also be placed three allegorical busts in white marble, representing Faith, Hope and Charity. All of the decorations will be marked by dignity and simplicity. The extensive working quarters on the three floors of the building will be equipped to accommodate all the branches of the Red Cross, with its varied activities in peace and war. On the first floor a large assembly room and library will take up all of one side of the building, and will afford a meeting place for the large gatherings of the organization. The central committee of the Red Cross will have special quarters. The War, National and International Relief boards will each have rooms particularly fitted for their special work. The army surgeon in charge of hospital field units and the enrollment of doctors, the first aid instruction department, the Nurses' Enrollment Bureau, the Town and Country Nursing Service and the Christmas Seal Division will all be quartered according to their

needs. Of the \$800,000 available for the memorial, \$357,000 was expended by the commission in the purchase of the site. The entire block surrounding the structure was acquired, and it will be laid out in parking, gardens and suitable approaches. Under the contract for the construction of the building, it will be completed and ready for occupancy by April 20, 1916."

TYPHOID MARY APPREHENDED.—After much difficulty, Mary Mallon, known as "Typhoid Mary," was discovered in hiding at Corona, N. Y., and arrested. She had fled there from the Sloane Maternity Hospital in Manhattan, after the outbreak of twenty-five cases of typhoid had occurred among the nurses and physicians of the hospital. She had been serving as cook at this institution under an assumed name, in spite of the fact that at the time of her release from North Brother Island on Feb. 19, 1910, she had signed a promise that she would not again take a position as a cook. Mary Mallon first came into public notice during an outbreak of typhoid fever at Glen Cove, N. Y., in 1906, when twenty-six cases developed.

RED CROSS CONTINGENT SAILS FOR SERBIA.—On April 3 the following members of the American Red Cross Sanitary Commission sailed on the *Duca d'Aosta* for Naples, where they will proceed, under the leadership of Dr. Richard P. Strong of the Harvard Medical School, to Serbia, in an effort to stamp out the epidemics of typhus and cholera raging in that unfortunate country. Dr. Thomas W. Jackson of Philadelphia is chief sanitary inspector of the commission; Dr. Hans Zinsser, bacteriologist; Dr. Andrew W. Sellards, Dr. George C. Shattuck, Dr. F. B. Grinnell, Dr. B. W. Caldwell and Messrs. W. S. Standifer, Luis de la Pena and Hobart D. Brink, sanitary inspectors. They will join Dr. Strong at Salonica. Dr. Strong sailed for Serbia several weeks ago and will be joined by the party at Salonica.

RIISING DEATH-RATE FROM DEGENERATIVE DISEASES.—Professor Irving Fisher of Yale University, one of the directors of the Life Extension Institute, in a recent address before the Twentieth Century Club emphasized the need of personal hygiene to offset the rapidly rising death-rate from degenerative diseases. That the death-rate from infectious diseases is constantly declining is due to the efforts of boards of health and health workers of all kinds, but Professor Fisher states:—

"There is need of a similarly vigorous fight against the degenerative diseases. By the degenerative diseases is meant those which consist in the degeneration, or wearing out, of the vital organs. It may be difficult always to distinguish between infectious and degenerative diseases, but that there is a broad distinction cannot be doubted. Our vital statistics show us that, while the loss of life from infection before middle age has decreased, the loss of life after middle age from

degeneration has increased. The truth is we are witnessing a race between two tendencies, a reduction of the acute or infectious diseases, such as typhoid, and an increase in the chronic or degenerative diseases such as arterio-sclerosis and Bright's disease. Such a process bids fair soon to change our net gain in the average life span into a net loss, unless we attack this degenerative problem very soon.

"The situation is especially alarming for us in the United States, because this tendency toward degeneration seems to be more in evidence here than elsewhere. In the United States the rate of life-lengthening is less than that for Europe as a whole, and our statistics show that the expectation of life after middle age is distinctly declining, while there is an ominous increase in the death-rate from the chief degenerative diseases. The number of people now dying from diseases of the blood vessels is nearly four times as great as three decades ago. This is found in the rural districts as well as in the cities, is found among the native-born as well as the foreign-born, and is found in all classes of males in gainful occupations, where a marked advance appears."

DEFEAT OF NEBRASKA EUGENIC BILL.—The lower house of the Nebraska Legislature defeated, on March 30, the new eugenic marriage bill patterned after the Wisconsin law. The bill was unpopular because women were exempted from its provisions.

NEW JERSEY STATE HOSPITAL, MORRIS PLAINS, N. J.—The thirty-ninth annual report of the New Jersey State Hospital for the Insane, at Morris Plains, N. J., contains the following statistics:

"During the year 2960 patients were under treatment—1500 men and 1460 women. The largest number under treatment at one time was 2522, on Sept. 30, 1914. The number of admissions for the year is 549—275 men and 274 women. There were remaining on Oct. 31, 1914, 2509 patients—1261 men and 1248 women. This is an increase in population of 98 over that shown in last year's report. There were discharged as recovered 83 patients. One hundred and eighty-four died—6.2% of the number treated throughout the year.

ERADICATION OF FOOT AND MOUTH DISEASE.—On Apr. 2, the United States Department of Agriculture issued at Washington a statement to the effect that with the exception of a small focus at Syracuse, N. Y., the recent epizootic of foot and mouth disease in this country is essentially at an end.

"Figures compiled by the department show that 124,141 animals have been slaughtered from the time of the outbreak in October to March 25 last. Interference with the operations of the stock yards at Chicago and other principal shipping points, the quarantining of infected regions and other precautionary measures, it was said, had caused indeterminable losses. Only a few

infected herds have been reported since March 25, and it was said all these had been slaughtered. Concerning the probability of future trouble from the disease, a statement by the department said:

"Although all the infected animals have been killed and buried, it is by no means certain that all possible means of conveying the infection have been destroyed. It is considered inevitable, therefore, that more animals will be stricken, but these should be only sporadic cases, which, if promptly reported, can be taken care of in time to prevent any further serious spreading of the disease.

"The \$2,500,000 emergency fund which Congress places at the disposal of the Secretary of Agriculture to combat contagious diseases, officials of the department said, was practically depleted in financing the war against the disease.

"Preliminary estimates place the actual cost to the Federal Government of animals killed because of the plague infection at between two and three million dollars. The government paid only fifty per cent. of the value of the animals slaughtered, the states, in the majority of cases, reimbursing the others with an equal amount. The total value of animals killed by both the state and federal authorities, therefore, would be between five and six million dollars."

LOOMIS SANATORIUM, LIBERTY, N. Y.—The annual report of the Loomis Sanatorium, Liberty, N. Y., for the year ending Oct. 31, 1914, records the work of that hospital in the care and treatment of tuberculosis. Three hundred and fifty-two patients were admitted during the year. Of the 289 patients to leave the hospital during the year 48 were apparently cured, the disease was arrested in 51 patients and 18 died. Those discharged as apparently cured had been under treatment at the sanatorium for an average number of 28.28 weeks; those discharged with disease arrested had been under treatment for an average length of 32.71 weeks.

FEDERAL CONTROL OF QUARANTINE.—Following the action of the City of Boston in transferring its municipal quarantine function to the National Government, the assistant secretary of the treasury has instituted a further active attempt to obtain federal control also of the quarantine stations at New York, Baltimore and Galveston, the only three which remain under local administration. In a letter on this subject to the governor of New York, the secretary writes in part as follows:—

"The taking over of the quarantine control at these ports on the Atlantic seaboard, it is expected, will have a far-reaching effect on public health in the United States, especially as it refers to the prevention of the introduction of quarantinable disease from Europe.

"Owing to the European war, these diseases, notably cholera, plague and typhus fever, are reported not only to have increased in volume in

certain points, especially in Serbia and Greece, but the spread of these diseases has been great in all directions. On this account the problem of quarantine at the various ports of the United States promises from now on to assume greater importance than ever before.

"Special apprehension is felt as to the chances of infection being brought in after the war is over, when immigration will doubtless increase in volume, and will include men and women from all walks of life from nearly all parts of Europe."

The same reasons which led the JOURNAL to advocate the transfer of the Boston Quarantine Service, make it desirable also that these remaining services should be placed under uniform national control.

HARVARD MEDICAL EXPEDITIONARY UNIT.—Report from Paris states that the Harvard Medical Expeditionary Unit reached Gibraltar safely on March 27 and arrived at Paris on March 30. On April 1, the members of the unit began their three months' term of service at the American Ambulance Hospital at Neuilly, relieving the unit from the Western Reserve University.

PROPOSED CHAIR OF MENTAL DISEASES.—A movement has been initiated under the sponsorship of Dr. Edward H. Bradford, Dr. William N. Bullard, Dr. Walter Channing and Dr. Philip B. Howard to raise a fund of \$150,000 for the endowment of a chair of mental diseases at the Harvard Medical School. The following preliminary statement has been issued by the sponsors.

"The suffering caused by insanity and allied disease is so widespread and so serious that efforts for its alleviation demand the most earnest attention and effective action. There is at present a special and crying need for assistance in this work. The undersigned, therefore, ask for money, viz:

"For research through the neuropathological department of the Harvard Medical School, where special opportunities now exist which should be taken immediate advantage of, and

"For the increase of instruction in the Harvard Medical School, through the endowment of a professorship of psychiatry (insanity and mental disease)—a subject for which adequate teaching has never been provided."

It is earnestly to be hoped that generous subscriptions to this fund may enable the early establishment of this valuable and important chair.

ANIMAL EXPERIMENTATION IN NEW JERSEY.—Report from Trenton, N. J., states that on March 29 the state legislature passed an important bill permitting the Rockefeller Institute for Medical Research to establish a laboratory for animal experimentation in New Jersey. This measure, which had been urgently opposed by anti-vivisectionists, was signed by the governor on April 6. The law provides for the super-

vision of these experiments by the state board of health.

EUROPEAN WAR RELIEF FUNDS.—On April 10 the totals of the principal American relief funds for the European War reached the following amounts:

	N. Y.	N. E.
Belgian Fund	\$1,017,159.19	\$245,979.52
Jewish Fund		56,945.05
Red Cross Fund	477,160.97	127,802.59
Committee of Mercy	141,869.20	
Prince of Wales Fund ...	116,744.48	
Polish Fund	36,454.35	40,336.41
Persian Fund	17,585.50	
Serbian Fund	1,719.00	

BOSTON AND NEW ENGLAND.

FITCHBURG BOARD OF HEALTH.—The report of the Board of Health of Fitchburg for the year 1914 gives a detailed record of the work of the bacteriologist, the agent of the board, the school physician, the school nurse, the board of health nurse, the inspector of milk, the inspector of plumbing, inspector of meats and provisions and inspector of slaughtering. The work of the school physician is especially interesting. During the year 11,373 examinations were made of school children, and 1303 cases referred to the school nurse, who made 1936 calls at the homes of the patients. Six hundred and seventy-eight children were found to have tonsils and adenoids requiring operative treatment. In many instances families, whose financial circumstances did not permit proper attention to the correction of defects, received aid through hospitals and the attention of the school nurse.

LOCAL EPIDEMICS OF MEASLES.—There are at present several local epidemics of measles in various Massachusetts cities and towns. During the three weeks preceding April 6, 400 cases of this disease were reported in Medford, 50 in Melrose, 50 in Malden and 150 in Wakefield. Many of the schools in these communities have been indefinitely closed until subsidence of the infection.

EXPERIMENTAL PATHOLOGY AT THE BOSTON CITY HOSPITAL.—It has been recommended by Mayor Curley to the trustees of the Boston City Hospital that a fund of \$20,000 be established in the pathological department of the institution for the special study of scarlet fever and measles in the effort to determine the etiologic agent of these infections and to discover a means for their cure and for immunization against them.

SOCIAL SERVICE AT THE MASSACHUSETTS GENERAL HOSPITAL.—The ninth annual report of the social service department of the Massachusetts General Hospital shows a commendable growth of activity and efficiency in the work of

this department. During the past year 823 patients were treated, 262 were referred from the children's department, 70 from the orthopedic department, 76 from the nerve clinic and 83 for sex problems. Donations to the general fund amounted to \$11,278.00, to the salary fund \$3,897.96, and for special purposes \$1,783.85. \$5000, as the nucleus of a permanent fund, has been given by Mrs. Shepherd Brooks. The usefulness of the department is dependent on its resources. The treasurer of the Social Service Department, Massachusetts General Hospital, will gladly receive contributions to maintain the rapidly increasing work of this movement.

HOSPITAL BEQUESTS.—The will of the late Frank W. Bolles of Boston, who died in this city on March 30, was filed on April 6 in the Suffolk Probate Court. It contains an immediate bequest of \$10,000 to the Channing Home, and on the death of the sole personal beneficiary, provides that the residue of the estate shall be equally distributed among various charitable institutions, including the Children's Hospital, the Perkins Institution for the Blind and the New England Peabody Home for Crippled Children. A codicil also contains bequests of \$15,000 to the Boston Home for Incurables, \$2000 to the Massachusetts General Hospital, and \$2000 to the Nurses' Alumni Association of the New England Deaconess Hospital.

CASES OF INFECTIOUS DISEASES reported to the Boston Board of Health for the week ending April 6, 1915: Diphtheria, 62, of which 5 were non-residents; scarlatina, 110, of which 14 were non-residents; typhoid fever, 2; measles, 183, of which 2 were non-residents; tuberculosis, 61, of which 2 were non-residents. The death-rate of the reported deaths for the week was 20.15.

POSTPONEMENT OF DR. SMITH'S DINNER.—Owing to the temporary illness of Dr. Theobald Smith, the dinner in his honor, to be held on April 17, has been postponed.

Massachusetts Medical Society.

PLYMOUTH DISTRICT MEDICAL SOCIETY. ANNUAL MEETING.—The annual meeting of the Plymouth District Medical Society will be held at the Commercial Club Annex, Brockton, April 15, 1915, at 11 A.M. Officers for the ensuing year will be elected and the annual oration will be given by Dr. Ernest B. Emerson, Medical Director, State Farm, Bridgewater. Subject, "Alcoholism."

ALFRED C. SMITH, M.D., *Secretary.*

Miscellany.

UNUSUAL GUNSHOT WOUNDS.

A CORRESPONDENT in a recent issue of the *British Medical Journal* records several instances of unusual gunshot wounds, and comments on the peculiar vagaries of modern rifle projectiles:

"In one case the bullet had entered just in front of the ear, and having passed through the body of the sphenoid, made its exit at a corresponding point on the opposite side of the face. Its track was perfectly straight, but though the wound was merely one of the face, it nevertheless proved instantly fatal. The reason was obvious on opening the skull and raising the brain. The under surface of the frontal lobes had been reduced to a structureless jelly. The case illustrates what has been said by more than one authority as to the bruising and devitalizing action a bullet may exercise on the tissues if at the moment of impact it is travelling almost at its initial speed. It might, perhaps, be expected that the greater the speed of the bullet the more knife-like would be its action on the tissues, but almost the converse would appear to be the case. The extent of the momentum possessed by a bullet which has not traveled more than 200 or 300 yards leads to the production of waves of force emanating from it in all directions the instant it meets with the slightest resistance; this seems all the more liable to occur if the initial impact of the bullet has not been at right angles to the general surface. In the present case the subsidiary lines of force seem to have been so powerful that even the fact that a bony diaphragm lay between the track of the bullet and the brain did not suffice to protect it. What are probably precisely analogous waves can be produced experimentally in many different ways. If a finger be passed through a basin of water the surface of the latter will be undisturbed if the movement be slow; if quick, a proportionate ripple will result.

"The second case was one in which the bullet had probably travelled a considerable distance—say, 1500 to 2000 yards—before it reached its mark, and its residual momentum was small. The wound was in the forehead and the bullet was found just inside it. Behind the bullet, however, and in a line with the hole in the forehead, was a track leading right through the brain to a distinct bruise on the inner plate of the occipital bone. It was concluded that the bullet, after penetrating the frontal bone and the brain, had struck the occipital bone and rebounded back along its original track. In this case there was no general bruising of the tissues surrounding the track, and it was considered that the momentum of the bullet on impact had fallen so low that when the frontal bone and brain had been traversed the elasticity of the oc-

cipital bone sufficed to drive it back. Cases in which the opposing forces are so nicely balanced must be rare. Clinically the different effect of fast travelling and slow travelling bullets is suggested by the fact that cases in which a bullet has penetrated but not perforated the skull are among the most hopeful of their class. It may be that in the case of the brain quite small differences in the momentum make very great difference in the extent of the injury inflicted. I have in mind cases in which the perforated portions of the brain have been seemingly identical but the clinical phenomena materially different.

"In the third case death was due to a penetrating wound of the chest. The opening was rather larger than is usual with those caused either by shrapnel or rifle bullets. On post-mortem examination, no foreign body of any kind could at first be discovered, but at length a rifle bullet was found embedded sideways in the body of a vertebra, that is to say, the long axis of the bullet was parallel to the long axis of the spinal column. The case was believed to be an illustration of the fact that rifle bullets sometimes turn over in their flight, for the character of the external wound and the position of the bullet in the vertebra were held to prove that it had struck and entered the chest when midway in a revolution round its short axis."

THE IATRO-CHEMICAL AND IATRO-PHYSICAL SECTS.

In a recent publication (*The Chemic Problem in Nutrition*), Dr. John Aulde of Philadelphia presents a sketch of the causative factors in disorders of nutrition as related to diseases of the nervous system. Apart from the clinical merits of his study of magnesium infiltration, the book presents an interesting collateral historical sketch of the iatro-chemical sect which was founded in the latter half of the 17th century:

"According to Sylvius, an industrious student of Van Helmont and Descartes, health depends upon the relation of the fluids, acid and alkaline, their union producing a neutral and milder substance. Two kinds of diseases were distinguished, the result either of acid or alkaline acidity. Among the prominent followers of Sylvius might be mentioned Willis, the celebrated English anatomist; Glauber, the discoverer of sodium sulphate (Glauber's salt), and many others; but iatro-chemistry gradually lost repute, and was completely overthrown early in the 18th century, principally through the teachings of Hoffmann.

"Founded upon more assumption and a smattering of chemistry, with no definite conception of physiology, iatro-chemistry was foredoomed to failure. It seems paradoxical, too, because this was a period of exceptional activity in laying

the foundations of medical science. Such names as Harvey, Steno, Vieussens, Malpighi, Spigelius, Bartholin, Asselius, Pauli, Mentel, Wesling, Highmore, Glisson, Wharton, Leeuwenhoeek, Ruysch, Sydenham, Boerhaave, Stahl, Albertini, Valsalva, Bellini, Swammerdam, Meibomius, Peyer, Duverney, Cowper, all belong to this period, and it is remarkable, to say the least, that they failed to distinguish the normal alkalinity of the building-up, from the normal acidity incident to the breaking-down processes in both animal and plant life."

The iatro-chemical was contrasted with the iatro-physical sect, a school of physicians also arising in the seventeenth century in Italy. The members of the iatro-physical school sought to explain the functions of the body and the application of remedies by static and hydraulic laws. They were earnest students of anatomy and were, perhaps, the intellectual and temperamental antecedents of modern professors of the mechanistic conception of life and its phenomena.

Correspondence.

TUBERCULOSIS AND LOCAL BOARDS OF HEALTH.

WEST NEWTON, MASS., April 2, 1915.

Mr. Editor: At the meeting of the Massachusetts Antituberculosis League yesterday, I was much impressed with the tendency of the readers of papers, especially of those holding state positions, to criticize and blame the local boards of health.

I believe if the readers had been more familiar with the trials and tribulations of local boards they would have been more lenient with them.

When we consider that the local boards are ground between the upper millstone of state statutes passed with little knowledge of or regard for local conditions, and the lower one of the local demand for economy, we should realize that they are to be pitied rather than blamed.

The member of the average local board of health is too often a man who has been appointed because no one else will take the job; he is seldom paid, and when appointed knows little or nothing about public health work, and yet is held responsible for the health of his community and required to pass upon questions of which he knows little.

I say this in the full knowledge that even so, he is an earnest, painstaking man, trying to do the best that he can in spite of his handicaps and that he usually "makes good."

It seems to me that such a man should not be blamed and ridiculed (for I regret to say that he was ridiculed), but should be praised for what he has done and helped to do better.

Too often the law, which he is blamed for failing to enforce, is so framed as to make conviction under it, difficult or impossible or, if he does attempt to punish the offender, the culprit is let off with a reprimand or the case dismissed.

If, instead of blaming the local boards, the state authorities would help them and explain to them how to solve their problems, I believe that we should see a great advance in efficiency in public health work.

When all is said, the state authorities and the local boards of health are but coordinate parts of the great system of health protection and they should work together in harmony, rather than find fault with and seek to make good at each other's expense.

Very truly yours,

FRANCIS GEO. CURTIS, M.D.,
Chairman, Newton Board of Health.

BELGIAN PHYSICIANS' RELIEF FUND.

F. F. SIMPSON, M.D., Treasurer,
704S Jenkins Arcade Bldg.,
Pittsburg, Pa.

In the ancient times there was a cry from Macedonia "Come and help us." St. Paul took that as the voice of God and responded with spiritual and mental pabulum. Today there is a cry from Belgium "Send us food or we perish." This is just as much the voice of God as the cry that reached St. Paul—and the response is even more necessitous. The pictures of wretchedness in that pitiful land grow more and more appalling from day to day. Miss Winifred Holt, secretary of the New York Association for the Blind, has just returned from Europe where she went in the interest of the blind Belgian refugees. She says there are no exact data but it is estimated that one person in every 1200 in Belgium was either partially or totally blind, or about 8000. When Belgium became the hotbed of war there were thirteen institutions for the blind, deaf and dumb. These were all wrecked and their sorry inhabitants poured forth in a mad rush of surging masses of blind men and women and children, seeking such guidance as they could get groping for places of safety. They must now be scattered among the helpless, starving, unfortunate refugees standing in the breadline that stretches all over Belgium.

The president of the National Relief Commission of Brussels asserted on March 25, that before the next harvest, 2,500,000 Belgians will be in the bread-

line. Foodstuffs must be continued to be provided in the fairly regular way in which they have been supplied heretofore. Belgium has been saved from the intermittent periods of starvation by the personal sacrifices of the Directors of the American Commission who have at these times pledged their personal credit for as much as \$10,000,000. All honor to the Commissioners.

We of the medical profession of America must see to it that our Belgian colleagues and their families are saved from such intermittent periods of starvation by keeping the stream of food and supply boxes pouring in to them in a steady flow.

J. RIDDLE GOFFE, M.D.,
New York, N. Y.

BELGIAN SCHOLARSHIP COMMITTEE.

The Belgian Scholarship Committee, of Washington, D. C., has recently issued the following circular letter of appeal in behalf of destitute Belgian scholars, and in anticipation of the future needs of Belgium during its period of educational reconstruction:

"In consequence of the devastation of Belgian museums, libraries and universities, numerous worthy students, research workers and professors, many of them crippled for life, are interrupted in their important work. To the lovers of equity, and to those who cherish education and admire Belgian integrity and heroism, an opportunity is hereby given, to assist in bringing to America, worthy intellectual men and women for a temporary free enjoyment of the privileges of American institutions.

"This committee has already received assurances from the George Washington University for the instruction of ten students in any of the departments of the University. The following is from the minutes of the Board of Trustees: 'On motion it was resolved that the University offer, within the discretion of the president, free tuition to the extent of \$1500.00 to European college students who are unable by reason of present conditions in Europe to pursue their courses at their respective colleges.' It is highly probable that the committee will receive from other American institutions similar assurances.

"It is proposed to raise a fund at once to defray the traveling expenses to and from Belgium, and the cost of residence in Washington for a period of one year, of the students or research workers, which the George Washington University has already generously provided for. In the case of professors it is hoped that the subscriptions will be sufficiently liberal to provide for honorariums as well, thereby giving all the students in Washington the benefits of lectures by Belgian scholars.

"It is estimated that from \$20,000 to \$25,000 will be needed in the work at once, and in the event of a surplus being accumulated, it is proposed to apply this to the recuperation of educational work in Belgium. This committee is a sub-committee of the Central Committee for the Belgium Relief Fund for women and children and other non-combatants, and it is organized with the approval of his Excellency, the Minister from Belgium to the United States.

"Please draw checks payable to Belgian Scholarship Committee, John Joy Edson, Treasurer, Washington Loan and Trust Building, Washington, D. C. Checks for any amount, large or small, are earnestly asked for. Please send something.

"NEVIL MONROE HOPKINS, *Chairman.*"

BELGIAN RED CROSS.

The following letter from Dr. Depage of Brussels, to the American medical profession, has been recently

received. In another column of the JOURNAL is a statement of a meeting to be held in an attempt to carry out the requests which Dr. Depage makes.

BRUSSELS, January 23, 1915.

My dear Colleagues: It is not without emotion that, in this time of trouble, I recall the sympathy with which you welcomed me some months ago.

In free and proud America, at the meeting of our International Congress of Surgery, of which I had the honor of being President, we all felt equally united not only in our scientific work but also in the entertainments which expressed the cordial hospitality and fraternal feeling with which you received us.

We did not dream then of the events which were going to happen, of the complete overthrow of Europe, and of the unmerited misfortune which has stricken down my country. However, our Congress opened with a discussion of surgery in war; and I then expressed this idea (alas, prophetic), that just as the armor-plate of battleships is increased in accordance with the increase of the power of projectiles, so the science of surgery should progress step by step with the increase of the strength of armaments, and should contend by all the means of human creative genius against the demon of destruction.

Present events have proven, only too well, the justice of this point in view. Nevertheless, let me again today affirm to you my opinion, and let me join you in the hope that the peace of tomorrow will bind the United States of Europe and the United States of America in eternal bonds of brotherly love.

In the meantime the situation in which we find ourselves is truly tragic. The Belgian Red Cross finds itself confronted by conditions which are unique in its history. The country, after a heroic defense, has been almost entirely overrun: its cities destroyed, buildings annihilated: installations confiscated by the enemy; its resources wiped out. That is the sad picture it presents. The Belgian population has been compelled to flee the country; our wounded are forced to seek asylum in foreign lands. Others have told you, others will tell you again, of the pitiless character of this war. As for me, as a doctor, I wish during the war to occupy myself with but one thing,—the care of the wounded. My sole preoccupation is to save human lives, and sometimes to save what is more precious than life, when by preventive measures, we can save the wounded from becoming crippled for the rest of their existence.

And so I face the situation in which our Red Cross work finds itself in this war, and I seek for means to assure to our soldiers the care which they expect from us. We have before us a ravaged country which offers no shelter for our hospitals, no implements, no resources of any kind. We are, therefore, face to face with the necessity of reconstructing entirely our hospitals and ambulances and of furnishing them completely with all necessary supplies.

Up to the present, England and France have helped us greatly. For the aid they have given we are profoundly grateful, but their resources are not inexhaustible and our needs are constantly increasing. America, I know, has already given generously to Belgium. Encouraged by your brotherly sympathy, I ask you for still more, and I send you my faithful collaborator, Madame Depage, who accompanied me on my last visit among you. The Managing Committee of the Belgian Red Cross has appointed her for the purpose of organizing, in its name, an American-Belgian Committee which will centralize all contributions and forward them directly and promptly, so that we may continue our work and meet our needs.

We thank the great American nation which, in the saddest hour of our history, has given us such generous help. I appeal specially to you, my dear colleagues, and I ask you to help me in my effort. I know you well enough to feel sure that I shall find in you the most fraternal and devoted assistance. I thank you in advance, and, in the name of the Red

Cross of Belgium, as well as in the name of the whole country, I express to you our profound and sincere gratitude.

A. DEPAGE,

Professor of the Surgical Clinic,
of the Free University of Brussels;
President of the International Congress
of Surgery, New York, 1914.

Director of the Belgian Red Cross with
the Belgian Army.

It is earnestly hoped that the medical profession will respond to this appeal made by our colleague in his time of need.

J. COLLINS WARREN, M.D.

GEORGE H. MONKS, M.D.

S. J. MIXTER, M.D.

NOTICE.

THE CUTTER LECTURE on Preventive Medicine and Hygiene will be given by Victor C. Vaughan, M.D., Dean of the School of Medicine and Surgery, University of Michigan, on the subject, "The Phenomena of Infection," on Wednesday, April 14; Thursday, April 15; and Friday, April 16, at the Harvard Medical School, Amphitheatre, Building E, 5 to 6 p.m.

These lectures are given annually under the terms of a bequest from John Clarence Cutter, whose will provided that the lectures so given should be styled the Cutter Lectures on Preventive Medicine, and that they should be delivered in Boston, and be free to the medical profession and the press.

The members of all classes in the medical school, the medical profession, the press, and others interested are cordially invited to attend.

SOCIETY NOTICES.

NEW ENGLAND PEDIATRIC SOCIETY.—The thirty-eighth meeting of the New England Pediatric Society will be held in the Boston Medical Library, Friday, April 30, 1915, at 8.15 p.m.

The following papers will be read:

1. "Can the Speech Present a Sign of Congenital Syphilis?" W. B. Swift, M.D., Boston.

2. "Acute Otitis Media in Childhood; Avoidable Mistakes in Diagnosis, Prevention, Treatment." W. R. P. Emerson, M.D., Boston.

3. "Studies in Bronchial Glands." W. W. Howell, M.D., Boston.

4. "Endocarditis in Children: Its Prophylaxis and Treatment in an Out-Patient Department." R. S. Eustis, M.D., Boston.

Light refreshments will be served after the meeting.

E. M. BUCKINGHAM, M.D., *President*.

RICHARD M. SMITH, M.D., *Secretary*.

MIDDLESEX SOUTH DISTRICT MEDICAL SOCIETY.—The annual meeting of the Society will be held at the American House, Boston, on Wednesday, April 21, 1915, at 11 a.m. The annual oration will be delivered at 12 o'clock, noon, by Dr. William C. Hanson, of Belmont. Subject: "Scope of Public Health Service."

Dinner will be served at 1 p.m.

LYMAN S. HAPGOOD, M.D., *Secretary*.

6 Garden St., Cambridge, Mass.

HAMPDEN DISTRICT MEDICAL SOCIETY.—The annual meeting of the Hampden District Medical Society will be held at the Academy of Medicine Building, 349 State St., Springfield, on Tuesday, April 20, 1915, at 4 p.m.

Election of officers.

Papers for the afternoon:

"The Diagnosis of Stomach Conditions from Tube Findings," P. M. Cort, M.D.

"The Diagnosis of Stomach Conditions by the

Roentgen Ray." Illustrated by lantern slides. H. W. Van Allen, M.D.

Discussion.

Luncheon at expense of Society.

HERVEY L. SMITH, M.D., *Secretary*.

APPOINTMENTS.

Dr. John R. Murlin of the Cornell University Medical School, has received a temporary appointment as biochemist at the pellagra hospital of the United States Public Health Service at Spartanburg, S. C.

Dr. Andrew Hunter of the Cornell University Medical School, has been appointed professor of pathological chemistry in the University of Toronto.

Dr. R. Travers Smith has been appointed professor of materia medica, therapeutics and pharmacology in the School of Surgery of the Royal College of Surgeons of Ireland.

RECENT DEATHS.

DR. GEORGE DICKINSON THAYER, a Fellow of The Massachusetts Medical Society, died at his home in Northampton, Mass., March 16, of heart disease, aged 57 years. Dr. Thayer had been county physician for thirty-two years and city physician for nine years. He was a graduate of New York University Medical College in 1881, and joined The Massachusetts Medical Society in 1882.

DR. WILLIAM J. DOUGHERTY, who died on April 6 at Beverly Farms, Mass., was born at Lowell, Mass., in 1882. He studied medicine at Tufts College and at the Johns Hopkins University. He is survived by his widow and by one son.

DR. CHARLES FESSENDEN NICHOLS, who died on April 5 at West Roxbury, Mass., was born in Salem, Mass., on February 20, 1846. He received the degree of M.D. in 1870 from the Harvard Medical School and subsequently practised his profession in this city until his death. He was a member of the Harvard Medical Alumni Association and of the American Institute of Homeopathy. He is survived by his widow, one daughter and two sons.

DR. JAMES COUGHLIN O'DONNELL, who died on March 30, at Northampton, Mass., was born at Florence, Mass., in 1871. He received the degree of A.B. from Holy Cross College in 1892 and subsequently studied medicine at the New York College of Physicians and Surgeons, and later at the Harvard Medical School, from which he received the degree of M.D. in 1899. After serving for a time as house officer at the Boston Children's Hospital and at St. John's Hospital in Lowell, Mass., he settled in the practise of his profession at Haverhill, Mass., subsequently removing to Northampton in 1895. He was unmarried.

DR. MANTON HOLLY, who died of pneumonia on April 7 at Greenwich, Conn., was born in New York City on March 28, 1833. He studied medicine at the Yale Medical School and at the New York College of Physicians and Surgeons, and served throughout the Civil War as surgeon in a military hospital at Washington, D. C.

DR. WILLIAM ORRIS MANN, Superintendent of the Massachusetts Homeopathic Hospital, died in that institution, April 9, aged 45 years, following a surgical operation. He was born in Randolph, Mass., and was a graduate of the Boston University School of Medicine in 1892. He was president of the American Hospital Association and a Fellow of The Massachusetts Medical Society. He is survived by his widow and two daughters.

Address

JOHN HALLE.

ANATOMISTE, CHIRURGIEN, MODERNIST.*

1530—1600.

BY CECIL K. DRINKER, M.D., BOSTON.

It is an easy task to select the great medical figures of the 16th century and to follow them with fair success through their eventful careers of scientific exploration. These giants have their due today and their lives, as expressed by imaginative achievement, are fairly opened to us. But even so, we are woefully lacking in intimate knowledge of the way they worked, and especially of the conditions which surrounded their early training. If this is true of the great, it is obvious that even more difficulty must attend attempts to get at the true status of medical practice at such a time. The ordinary doctors in an extraordinary period; what general practice meant in these dark days; how the country physician fought through his prosaic rounds—these have been my interest, and I shall illustrate them by passages from the life of John Halle, an Elizabethan country doctor practising in Kent in the little village of Maidstone.

This man slightly antedates Harvey, living from 1530-1600. He has left us the first work upon anatomy published in England in the English tongue. Vicary's Anatomy appeared in

* Read before the Historical Club of the Harvard Medical Society, January 5, 1915.

1577, fifteen years after his death, and while there is a tradition that the first edition came out in 1548, no one even knows upon what basis such an idea has risen. Halle's Anatomy is not in the least valuable nor creditable from the point of view of original observation. It appeared in 1565 and is appended to his translation of the *Chirurgia Parva* of Lanfranc. He called it "A compendious worke of Anatomie more utile and profitable, than any heretofore in the Englyshe tongue published." The "worke" is indeed "compendious" as regards the anatomy, there being but ninety-six pages for the whole subject. We may say that the "Anatomie" is of the 14th Century, the work of William of Salicet, Lanfranc and Guy de Chauliac redressed to suit his English readers, and disappointingly barren. But in defence of Halle we may contend with safety that it is quite as good as Vicary's *Profitable Treatise of the Anatomie of Man's Body*. Halle, however, was a provincial surgeon, while Vicary was one of the best known surgeons of his day, being First Master of the Barber Surgeons and attached to the courts of Henry VIII, Edward VI, Mary and Elizabeth.

Fortunately for us, medical authors were not overwhelmed by material in those good days nor trammelled by conventionalities of method, so that our anatomist and surgeon feels at liberty to favor us with his general views upon practice, his ideas upon methods of study, and last and evidently most vital to him, with a fierce arraignment of the quacks who seem to have tormented him incessantly in his quiet country village.

Facsimile: Frontispiece.

There is not a dull moment in this old book, nor one in which the reader does not feel himself the intimate friend of this most worthy, gracious and sometimes pugnacious author. The dedication, "Unto the Worshipful, the Maisters, Wardens and consequently to all the whole company and brotherhood of Chirurgiens of London, John Halle, one of the lest of them, sendeth hartie and lovyng salutation," is followed by an epistle which indicates the chief reason for his work, namely, to spread knowledge which shall put a stop to the activities of false practitioners whose incessant mistakes and mercenary minds are dragging medicine into disrepute.

"And alas," he says, "whereas there is one in 'Englande,' almoste throughout all the realme, that is indede a true minister of this arte, there are tenne abominable abusers of the same,

Whereas there is one Chirurgien, that was an apprentice, to his arte, or one phisicien that hath travayled in the true studie, and exercise of physiqe; There are tenne, that are presumptuous smearers, smaterers, or abusers of the same: Yea, Smythes, Cutlers, Carters, Coblars, Copars, Coriars of lether, Carpenters, and a great rable of women: Which (as the moste excellent Galen feared to happen) forsake their handiecraftes, and for filthy lucre abuse phisick and chirurgerie.*

"Would to God therefore, my dere maisters and brethren, that there might be no fault found in us concerning these things. For truly

* Compare William Clowes (1540—1604) who complains of medical practice by "tinkers, tooth-drawers, peddlers, ostlers, carters, porters, horse-gelders and horse-leeches, idiots, applesquires, broom-men, bawds, witches, conjurers, soothsayers, and sow-gelders, rogues, rat-catchers, runagates, and proctors of spit-the-houses."

if we weare such men of science, as we ought to be, those false abusers would be more fearful to meddle as they doe. For what a shame were it, that such an abuser in talkinge with a chirurgien in ded, shall apere more perfect in the knowledge of the anatomie, and the natures of simples, or the complexion of man his bodie, then he that hath been apprenticed to his arte? Surely me thinketh this were a great occasion, not only to cause these abusers more to presume: but I fear me also that suche things have bene the cause, that suche abusers have bene defended, of those which of right shoulde have subdued them." After a brief note upon the merit of Lanfranc's work and mention of the addition of his own brief anatomy, the worth of which he leaves his brethren to judge, he ends with a tremendous blast against all abusers of medicine.

Following this dedication are letters from two of Halle's surgical friends, William Cunningham and Thomas Gale,* commending his work and his good spirit. These notices are in the same vein of frank extravagance which we see today in the book reviews of many medical journals. One of them, Gale, mentions a curious point of view, but one which in his day was perhaps more practical. John Halle seems to have told his friends of his intention to publish his work in English and of his desire to spread information in this way. Whereupon it was held that in making scientific matters so plain to everyone he would open medical practice to even greater abuse. Halle later refers to the same objection, saying: "I am not ignorant, that some men will thinke, that this booke (beyng

* Thomas Gale (1507-1586?) a surgeon and author of *An Excellent Treatise of Wounds Made by Gunneshot* (London, 1563).

A most excellent and LEARNED VVOORKE OF CHI-

rurgerie, called Chirurgia parua Lanfranci,

publyshed) wyl be an occasion for such men to be the bolder to abuse the same science. But I know and am sure, that they shall not learne in this booke anythyng wherewith to hurte; neither have I publyshed the same for them. And farther if any abuser of chirurgery reade this boke, he shall (I trust) so fynd himself rubbed on the galle, that he shall be moved (if he have any shame) to leave his vice, rather than more to use it."

And now John Halle, having fulfilled all the formalities and attended to his advertising, turns his attention to his "lovyng Readers," to whom he gives "greeting in our eternal Lorde, the author of all knowledge," and sets forth more explicitly the scope of his work. In this, which is the real preface, we are told of the parts of medicine, "Physiologia, Pathologia, and Therapeutica," and how "these III are together (as most necessary partes of one body), so joyntly united, that neither the last can anything profit withoute the first and seconde, nor the first be perfect and utile withoute the seconde, and thyrd, etc. So doubtlesse can the professor of neither part lack any portion of the whole, without so great imperfection as is his lacke." Therapeutics in its turn divides itself into "Dietetice, Pharmaceutice, and Cheirurgie." As time passes these three parts of what should be one profession are becoming three professions and this against the express advice of the ancient authorities. "But," we are told, "let the present tyme be judge therein, howe much hurte the same causeth. For the persones professing either of these partes are so in hate with the other partes, that they thynke it a dishonor to be acquainted one with another. . . the physiciens or professors of the dietetike parte, abhorre chirurgie, as a thyng to vyle for their profession. And they that are chirurgiens, estemyng their profession to bee only one part of physicke, and that for the exterior partes of manne's bodie, regarde not to be learned thynkyng that it is not nedeful to their arte. And likewise the pharmaceutike parte, trustyng to the learnyng of the physicians and chirurgiens, thynke it no boote to be learned themselves. In so much that olde women must gather their herbes, unto whom they trust for the truth of thynges, rather than to their owne knowledge. And the physiciens havynge only learning, truste to the chirurgiens and apothecaries for experience; and yet in the meane season hatynge either or both, if they medle in the dietetike parte; so that betwene trustyng and hatynge one an other, they are all void and destitute of perfection."

Halle is a surgeon and it is with those who attempt surgery that he is most concerned. The properties and conditions of a surgeon are defined very carefully. "A chirurgien," we are told, "should have three dyvers properties in his person. That is to saie, a harte as the harte of a lyon, his eyes like the eyes of an hawke, and his handes as the handes of a woman.

"Seyng also, that those auncient authors had not only this regarde to the forme of the body, but also and as well to the bewtie or ornament of the mynde, and honest conversation of hym that should be admitted to chirurgery, as are these; He ought to be well mannered, of good audacitie and bolde where he may worke surely, and contrarywyse doubtfull and fearfull, in things that be dangerous and desperate. He must be gentyll to his pacients, witty in prognosticoes, apte and resonable to answer and dissolve all doubttes and questions belongyng to his worke. He must also be chaste, sober, meke, and merciful, no extorcionier, but so to accomplishe his rewarde at the handes of the ryche, to mayntaine his science and necessary lyvynge, that he may help the poor for the only sake of God."

Next the young student begins to get direct advice. He is warned against an apprenticeship with a man who wishes a drudge and will keep him for seven years, not daring to teach anything lest his own ignorance become apparent. Gaming and other typical pleasures of medical students, must be avoided, forsaken for knowledge, his one pursuit. "Let thy boke, therefore, I saye, be thy pastyme and game: which (if thou love it as thou oughtest) will so delight thee, that thou shalt thinke no tyme so well bestowed as at it. Yea thou muste desyre it as the childe doeth his mother's pappe; and so will it nourishe thee, that thou shalt worthily growe and increace to a worshypfull fame of cunnyng and learnyng."

And now we come upon the translation of Lanfranc which, however, does not illustrate conditions of practice as well as the last division of the book entitled "An Historiall Expostulation also against the beastly abusers, both of Chyrurgerie and Phisicke in our tyme: with a goodly doctrine, and instruction necessary to be marked and folowed by all true Chirurgiens."

In the "Expostulation" we are fortunate in having an account of some of the quacks who came into Halle's village.

"In the year of our Lord a thousand fyve hundred fyftie and eyght, there came to Maydstone one Thomas Lufkyn, by occupation a Fuller, a bueler of clothe, and had bene brought up (by report of divers honest men) at the fullynge mylles there besyde the towne, nevertheles he had been long absent from that countrie, in which tyme he had by roving abroad become a Physicien, a Chirurgien, an Astronomer, a Palmister, a Physiognomier, a Sothsayer, a Fortunte Devyner, and I cannot tell what. This deceaver was the beastliest beguiler by his socerys that ever I herd of, making Physike the onely colour, to cover all his crafty thefts, and mischief, for he set oppe a byll at his fyrste comynge, to publishe his beyng there, the tenour whereof was in effect as followeth:—

"If anye manne, womane or childe, bee sycke, or would be let bloud, or bee diseased with anye maner of inward or outward grefes, as all maner of agues, or fevers, pleurisies, cholyke,

stone, strangulion, impostumes, fistulas, kanker, goutes, poekes, boneache, and payne of the joynts, which cometh for lacke of bloud lettyng: let them resorte to the synge of the Saracen's hedde, in the easte lane and brynge their waters with them to be sene and they shall have remedie.

.....By me Thomas Luffkin.'.....

"Unto this Divell incarnate resorted all sortes of vayne and indiscrete persons, as it were to a God, to know all secretes paste and to come, specially women, to know how many husbandes and children they shoulde have, and whethere they should burie their husbands then lyving. And to be brefe, there was not so great a secrete, that he would not take upon to declare; unto some he prophecied death within a month who thanks be to God are yet lyving and in healtie. All this he bosted he could do by Astronomie. But when he was talked with of one that had but a yonge and smalle skylle in that arte, he could make no directe answer no more than puppe my dogge.

"Amonge manye that talked with him, one of mine acquaintaunce asked him this question: Sir, quod he, if you be so cunnygne as ye are named or as you would fayne be esteemed to be, Wherefore goe ye, and travaile ye, from place to place: For beinge so cunning, ye cannot lacke wheresoever ye dwell: for people will resort unto you farre and nere: so that you should not neede thus to travaile for your livynge. Unto whom he made thys beastlye answer: I know, quod he, by Astronomie the influence of the starres and thereby perceave, when and howe long any place shall be unto me fortunate; and when I perceave by the starres, that any evell fortune, is like to chance to me in that place: I streighte waye wiselye avoid the danger, and goo to another place where I knowe it will be fortunate and luckye."

After a career which seems to have been immensely annoying to Halle, this "beastlye deceaver" begins to be understood by the people and takes himself off with all the money he can lay his hands upon. He is interesting to us because of his use of a bill of advertisement and because of his mention of the current superstitions. How exactly similar to the tactics of Luffkin were those of the itinerant quacks of the early nineteenth century and indeed, though they are not seen so commonly, of today!

Another example gives evidence that Halle is blessed with a pleasant sense of humor:—

"In the yere of our Lorde, 1556, there resorted unto Maydstone one Robert Haris, professynge and pretendynge an hyghe knowledge in Physike; under cloke whereof he deceaved mervaylouslie with vyle Sorceries. This deceaver could tel (as the folish people reported of hym) by only lokynge in one's faee, al secrete markes and scarres of the bodie, and what they had done, and what had chanced unto them all their lyfe tyme before. Wherewith he had so incensed the fonde and waverynge myndes of

some, that pitye was to here. Amonge whome one woman (whoe for her yeares and profession, ought to have been more discrete) when I reasoned with hir agaynste his doynge; she earnestlie affirmed, that she knewe well that he was then dystant from hir, at the leaste VII myles, and yet she verelye beleved that he knewe what she then sayde.

"Well for settinge a lytell agaynste the madness of this deceaver, I hadde a dagger drawne at me not longe after.

"The wordes that I spake were to his hostess, when I saw him goe by in this wyse. Is this (quod I) the cunnygn sothsayer, that is sayde to lye at your house: Sothsayer, quod she, I knowe no suche thyng of him, therefore ye are to blame so to name him. Why quod I, suche men and suche enformed me that he can tell of thynges loste, and helpe children and cattell bewitched and forspoken, and can tell by lokynge in one's faee, what markes he hath on his bodie, and where, and tell them what they have done, and their fortune to come. Yea and all this he can doe quod she. Why then he is a Sothsayer and a Socerer quod I. Well quod she yf he have so muche cunnyng in his bellye, he is the happyer, and it is the more joy of him. Nay quod I, it were mere folyshness for hym to carye his cunnyng in his bellye: and why quod she. Why quod I, thynke you that men of lerning and knowledge cary their cunnyng in their bellies: Wher els quod she, and why not. Mary quod I, yf he should beare his cunnyng there, he should alwayes waste it when he went to the privye, and so in tyme he should lose all his cunnyng. Thys beyng merylye spoken turned me afterwards not to a little displeasure, even at their hands where I had deserved and loked for friendship as of dutie."

Last of all, and after an exhibition of most commendable restraint, Halle closes with a little more advice to the "younge studentes" in the form of a poem of fifty-six verses. The poetry is alarmingly bad, but expresses a number of interesting ideas and practices which may be given by a selection of verses.

"Harke and drawe nere, ye younge studentes.

Your eares loke ye uncloze:

The worthy art of Chirurgery.

To practise that purpose.

"When thou arte calld at anye time,

A patient to see:

And doste perceave the cure to greate.

And ponderous for thee.

"Gette one or two of experte men.

To helpe thee in that nede:

And make them partakers wyth thee.

In that worke to procede.

"And if it happe to frame amisse,

Suspicyon can be none:

Sythe thou haste soughte all means of healtie.

And wouldste not be alone.

"But one thyng note, when two or more

Together ioyned be.

About the paynfull patient,
See thatt ye doe agree.

"See that no discorde doe arise,
Nor be at no debate:
For that shall sore discomfort hym,
That is in Sycke estate.

"And when alone with your sore man,
One of you is presente:
Defame nor dispraise in no wise,
The same that is absente.

"With one consent uniformlye
Comforte the wounded man:
But unto some good frende of hym,
Expresse all that ye can.

"And let them know the dannger greate,
That like is to succede:
Prognosticatinge wittilye
And in convenient spede.

"Not onlye in Chirurgery,
Thou oughtest to be experte:
But also in Astronomye,
Both preveye and aperte.

"In naturall Philosophie,
Thy studye shoulde be bente:
To know eche herbe, shrubbe, roote and tree,
Must be thy good intende.

"But chiefllye the Anatomye,
Ye oughte to understande:
If ye will cure well anythinge,
That ye doe take in hande.

"For by the same above the rest,
Ye shall greate fame deserve:
The life of man from many streightes,
To save and well preserve.

"Withoute the knowledge of whyche arte,
Thou canste not chose but erre:
In all that thou shalte goe aboute,
Thy knowledge to preferre.

"As if ye cutte or cauterize,
Or use Phlebotomye:
Ye can not but erre in the same,
Withoute Anatomye.

"Endevoure therefore by all meanes
The same to knowe and kunne
For when thou haste it perfectlye
Thine arte is halflye wunne."

Original Articles.

A STUDY OF LEPROSY: WITH ESPECIAL REFERENCE TO THE PULSE AND TEMPERATURE.

BY JAMES A. HONEIJ, M.D., BOSTON,

From Penikese Hospital and the Department of Bacteriology, Harvard University Medical School.

A PRELIMINARY report was made in the BOSTON MEDICAL AND SURGICAL JOURNAL of Febru-

ary 12, 1914. Emphasis was laid on the possible prognostic value of the morning increase in pulse rate. The present detailed clinical study covers a period of twelve months from July 14, 1913, to July 14, 1914. In all, seventeen patients have been under observation for various periods during two years and fourteen patients have been under constant observation for eighteen months. These observations were carried out by the author with the assistance of two nurses and the coöperation of patients.

The study of the temperature and pulse has given definite results and the following points are now presented:—

1. There occurs a definite clinical temperature and pulse curve diagnostic and prognostic of leprosy.

2. There is a frequent and persistent occurrence of a high morning pulse rate—"morning pulse"*—in all cases.

3. A constant high pulse rate is most marked in progressive and advanced cases.

4. A persistent high pulse rate without a corresponding elevation of temperature of prolonged duration is found after "toxic-febrile"† attacks.

5. There is a correlation of temperature and pulse in early cases, in contrast to a gradual increase of pulse rate without similar temperature reactions in progressive and advanced cases.

6. Not uncommonly a low evening temperature is present.

7. A marked irregularity in temperature and pulse exists during complications not associated with leprosy.

8. There are typical "toxic-febrile" temperature and pulse curve reactions.

9. Marked temperature and pulse reactions occur from otherwise insignificant causes, both physical and mental.

These conclusions have been reached from the study of the cases which are given in the following table (page 581).

CASE 1. F. B. Sex, female. Age, 46. Social state, married. Nationality, Italian. Resident in United States, 7 years. Residence at Penikese, 3+ years. Diagnosis of leprosy made 4+ years ago. Type of disease, tubercular. Stage of disease, fairly advanced. Condition of disease, active-progressive. Most common lesions, tubercles and ulcers, marked induration. Dispensary attendance, frequent. Symptoms most marked, local swelling and pain, mental. "Toxic-febrile" attacks. Activities of patient, light housework. Disposition, depressed, irritable. Prognosis bad. Remarks, mental condition important factor. Eyes affected.

* "Morning pulse." This term is used throughout the article to denote a higher pulse-rate in the morning than in the evening.

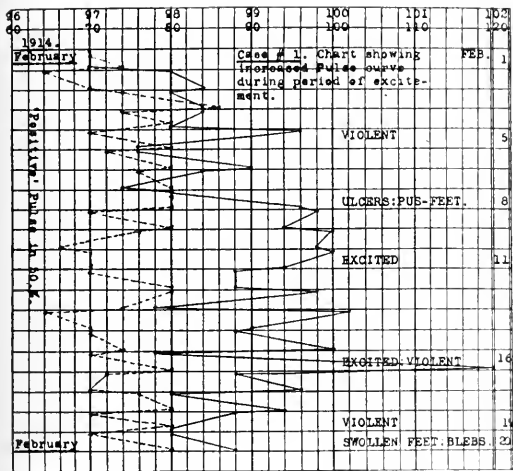

† "Toxic-febrile" (attacks)—a typical reaction characterized by rise of temperature and increase in pulse-rate with symptoms of an infection.

* Original cases of State Colony.
† Well advanced in the year.

CHART No. 1.

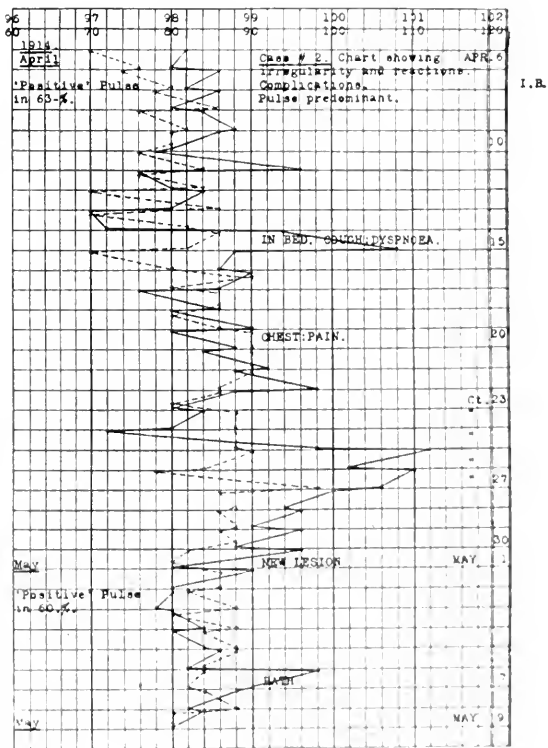

The chart of this patient represents a consecutive period of only six months, and is therefore of less interest and value for study. The patient is mentally unbalanced, highly excitable at times, and as a result is not always under control. The pulse curve gradually predominates during the course of the disease and is irregular, as expected. The morning rise in pulse rate is, however, present approximately 60+ % of the time. This phenomenon is more constantly present during the second four months than in the first period. January shows the characteristic "morning pulse" in 72+ % of the observations. February presents it in only 50%, even during excitement. An interesting point is brought out in this chart. The increased pulse curve during an excitable period shows no relation to the temperature curve. This observation is characteristic of reactions produced by nervous influences, which are not to be confused with the "toxic-febrile" reaction, as seen in the other cases. The disease is rapidly progressing. The lesions have been more frequent and severe during the last few months.

There has been considerable loss of weight during the year.

CASE 2. I. B. Sex, female. Age, 33. Social state, married. Nationality, Portuguese. Resident in United States, 12 years. Resident at Penikese, 8+ years. Diagnosis of leprosy made 8+ years ago. Type of disease, mixed. Stage of disease, advanced. Condition of disease, active-progressive. Most common lesions, ulcers, swollen glands. Dispensary attendance, frequent. Symptoms most marked, local swelling, and pain, cough, dyspnea. Two slight "toxic-febrile" attacks. Activities of patient, light housework, little amusement. Disposition,

CHART No. 2.

tion, depressed. Prognosis, bad. Remarks, pulmonary tuberculosis present.

The whole chart represents two distinct exacerbations during the twelve months. In December the temperature rose to 101° , the pulse rate to 88; in January the temperature reached 103° , pulse 122+. This was due to what may be termed a "toxic-febrile" attack, with localized swelling of the face, neck and glands, accompanied by pain and depression and marked prostration. The average morning pulse rate during January is high, notwithstanding the fact that recovery from the attacks in December and January had just set in. During April, May and June there were complications. The temperature and pulse were higher in this period, as shown in chart, with frequent exacerbations, which occurred particularly after catamenia. The pulse since December has been in excess of the temperature, and this is more marked from January to the present time, giving an indication of the progressive, serious condition of the patient. Slight disturbances in the course of the disease have reacted in a rise of temperature and pulse.

The interesting points in this chart are: 1, the high "morning pulse" rate covering over 70% of the whole period; 2, the exacerbations of the last four months, with greater irregularity of both temperature and pulse and the higher average of both compared with the previous two periods of four months, being $1+^{\circ}$ and 10+ beats higher; and the low evening temperature for the last eight months, which existed nearly one-third of the whole time. Loss of weight has been extreme.

CASE 3. H. C. Sex, male. Age, 28. Social state, married. Nationality, Chinese. Resident in United States, 13 years. Resident at Penikese, $1\frac{1}{2}$ years. Diagnosis of leprosy made 2 years ago. Type of disease, anesthetic. Stage of disease, early. Condition of disease, inactive. Most common lesions, macular areas. Dispensary attendance, none. No symptoms. No "toxic-febrile" attacks. Activities of patient, fishing, washing, playing. Disposition, slight depression. Prognosis, good. Remarks, patient gained in weight. Pigmented areas disappeared. Discharged.

This patient has been discharged as an arrested case. During the six months previous to his discharge the temperature and pulse ran evenly and fairly regularly and correlated. The "morning pulse" was present less than 42% of the time. The only marked rise was a temperature of 103° and pulse 104 in October, lasting four days and due to a common cold. Three days previous to his discharge the pulse was high, but probably due to the excitement of his departure. The patient gained considerably in weight.

CASE 4. M. C. Sex, male. Age, 25. Social state, single. Nationality, Portuguese. Resident in United States, 6 years. Resident at Penikese, 2 years. Diagnosis of leprosy made 2 years ago. Type of disease, tubercular. Stage of disease, fairly

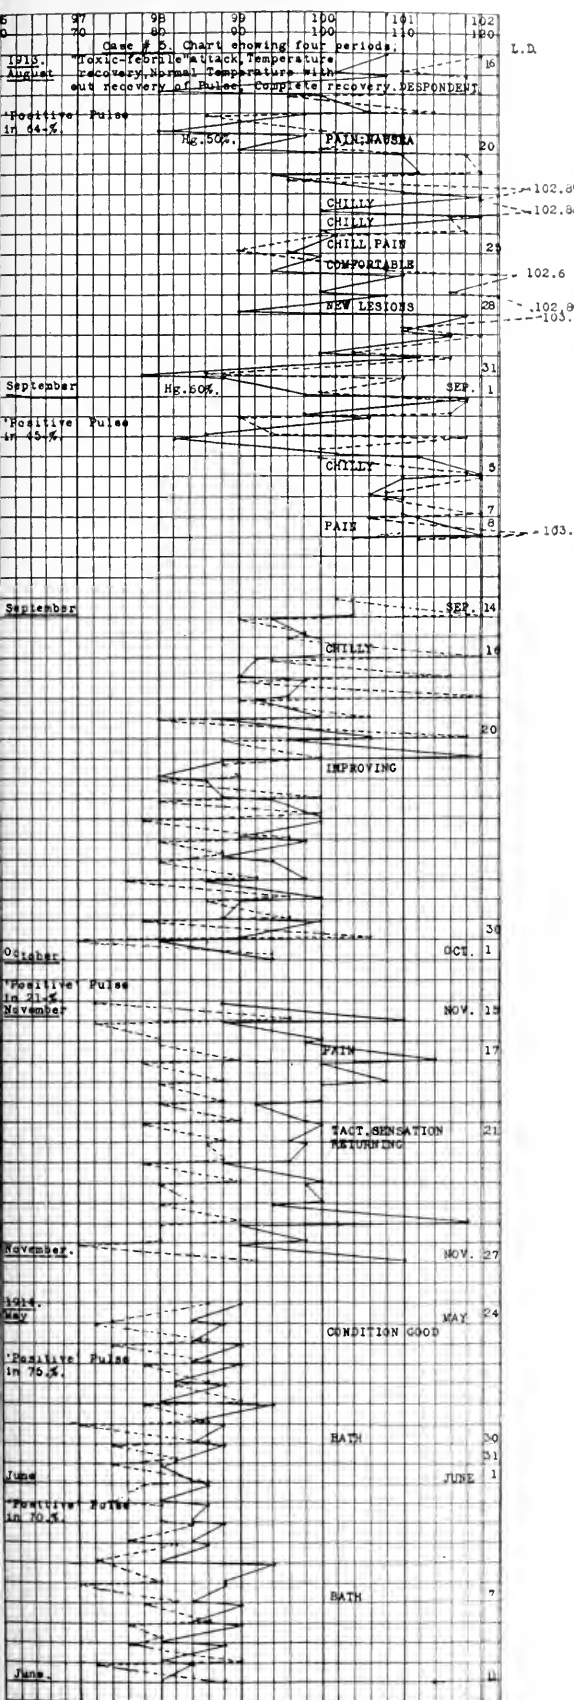

advanced. Condition of disease, active-progressive. Most common lesions, tubercles, ulcers, fissures. Dispensary attendance, frequent. Symptoms most marked, local pain and swelling. One slight "toxic-febrile" attack. Activities of patient, gardening, housework, cooking. Disposition, good. Prognosis, unfavorable. Remarks, questionable pulmonary tuberculosis.

The most striking point is the daily variation in temperature, which shows a marked elevation at night. This is more typical of tuberculosis than of leprosy, although in the former disease both the morning and evening temperature tends to be higher than in the present instance. During the first four months the pulse runs nearly parallel to the temperature. The next month, November, the pulse curve changes and shows a tendency to reverse to the "morning pulse" type. The temperature is higher during the first four months, but during the last four it is more variable. The pulse during the latter period is more rapid—the rate being higher in comparison with the temperature. There are few exacerbations, and only one noticeable elevation which was the result of a "toxic-febrile" attack with local swelling, pain and ulcers. During the first two months the pulse and temperature curves are parallel. The pulse curve gradually merges into the temperature curve, until the rise and fall is not synchronous with the temperature, showing the more consistent appearance of the "morning pulse" rise. The chart shows that during the first four months the pulse presented morning rises in only 24% of the readings and during the last four months in 47+%. During the first four months there were few lesions, but in the last period the lesions, which were consistent with the progress of the disease, were more frequent. No complications were found, although the dispensary attendance was more regular. The patient has lost a little weight.

CASE 5. L. D. Sex, male. Age, 35. Social state, married. Nationality, Chinese. Resident in United States, 12 years. Resident at Penikese, 8+ years. Diagnosis of leprosy made 9 years ago. Type of disease, tubercular. Stage of disease, fairly advanced. Condition of disease, active(?). Most common lesions, pustules, nodules, marked induration. Dispensary attendance, frequent. Symptoms most marked, pain, chills, local swelling. Several marked "toxic-febrile" attacks. Activities of patient, washing, housework, light amusement. Disposition, depressed, hilarious. Prognosis, fairly favorable. Remarks, lower legs have been most severely affected. Greatly improved.

During three-fourths of July, 1913, patient was in fairly normal health. The last one-fourth of the month the patient showed an acute "toxic-febrile" attack, presenting a rather sudden rise of temperature and pulse, accompanied by severe lesions, pain, chills, headache, nausea, extreme prostration and despondency. During August, this attack was at its height and gradually subsided with intermittent exacerbations

CHART No. 5.

or "reinfections" up to May of the following year, when temperature and pulse are nearly correlated as previous to the attack. Six weeks after the onset, the temperature was more regular, but showed high daily variations. The readings were low in morning and high at night until January, when a second serious attack occurred, with high and irregular temperature, extremely low in the morning and excessively high in the evening. From Sept. 21, just after attack, the temperature subsided gradually to 99°, but the pulse remained high and irregular up to the first of January. During this period, with the exception of the second attack, the pulse rate was high and out of proportion to the temperature, hovering around 110 and 120. From Feb. 7, just after second attack, a similar change took place, the temperature subsided much more genuinely, but the pulse remained high and irregular until it gradually merged during May with the temperature, and then ran parallel to it and within fairly normal limits up to the end of the year. During both attacks, the high "morning pulse" was present 65+ % of the time. During the recovery from these attacks, in October and November, the latter was much less evident. This was due to the fact that, although there was subsidence of temperature, the effect of the "toxic-febrile" attack was still present. During the last four months the average was practically 75%. Since this is a typical case, a careful study of the charts is warranted. The patient has gained in weight.

CASE 6. M. G. Sex, male. Age, 50. Social state, married. Nationality, Russian Jew. Resident in United States, 12 years. Resident at Penikese, 7 years. Diagnosis of leprosy made 9 years ago. Type of disease, tubercular (?), mixed. Stage of disease, slowly active. Most common lesions, bullae, ulcers, swollen glands, marked induration. Dispensary attendance, frequent. Symptoms most marked, pain, chills, swelling, throat. One severe and several slight "toxic-febrile" attacks. Activities of patient, light housework, cooking, light gardening. Disposition, nervous, slightly apprehensive. Prognosis, unfavorable. Remarks, throat causes considerable discomfort. Nerve involvement rapid.

This patient had a more or less consistent pulse during the year, although at intervals there was irregularity, most often accompanied by an equally irregular temperature. During the "toxic-febrile" attacks the chart shows the usual "pyramid" effect. For the first four months pulse and temperature were fairly parallel, during the last four months the pulse showed a greater ratio of change than the temperature and its increase was greater in proportion to the rise of temperature. There is nothing remarkable about the chart excepting that the average of the "morning pulse" rises for the year is 72+ %. The temperature did not often exceed 99°, and the pulse was most frequently between 80 and 90. The temperature showed an evening fall more than one-fourth of the whole time and at almost no time a rise of more than 1° above

the morning temperature. The patient does not show any tendency for the worse but rather a slow, gradual improvement, with indications of greater nerve involvement. Patient has held weight.

(To be continued.)

SKELETAL CANCER.

By E. H. RISLEY, M.D., F.A.C.S., BOSTON.

THE subject of skeletal cancer or bone metastases following operations, particularly for breast cancer, assumes a place of importance when we are considering prognosis and the limit of time to be set on what may be called a cure after radical operation.

The discovery of two late recurrences or metastatic growths in patients operated on for breast cancer, the one in the skull seven years after operation, and the second in the vertebral column nine years after radical operation, has led the author to try to set down in as brief and concise a way as possible the essential facts in regard to skeletal metastatic growths.

Such instances as the above make one skeptical in putting one's faith in any time-limit of cure and very guarded in one's own mind in making a prognosis, even after the most thorough and radical operative procedure.

The literature contains no extensive, thorough or detailed paper on this subject, probably because of its comparative rarity and the fact that many cases are discovered only at the autopsy table.

Von Recklinghausen in 1891 made the first careful study of skeletal carcinoma. This was done in the course of studies on cancer of the prostate. He was surprised at the frequency of bone metastases in prostatic malignancy. Since Von Recklinghausen, Handley is the only author who has published anything of distinct value on the subject. He devotes an entire chapter to bone metastases and theories of invasion in his most excellent book on "Breast Cancer and Its Operative Treatment."

Route of Metastatic Spread. There are two distinct theories in regard to the mode of invasion. The older and more common one being that of emboli in the blood stream. The second, that of centrifugal extension via the lymphatic plexus of the fascia. Handley sets this forth so convincingly that reference will be often made to his excellent exposition of the subject in discussing this question.

I think, however, that Handley's theory explains satisfactorily bone metastases from breast cancer only and that it may or may not apply to cancer metastasizing to other organs or from other organs.

Handley's theory, while accounting satisfactorily for bone metastases in the humerus and

femur is hardly convincing when applied to the lung, brain and possibly vertebrae and liver. In these we must give credit to the embolic theory.

His belief, however, asserts that metastases to the liver are via the lymphatic plexus of the abdominal wall down to and by way of the suspensory ligament of the liver to the liver substance itself.

To quote from Handley: "There is one fact with reference to secondary growths of the femur and humerus which seems at first sight strongly to suggest their origin from emboli carried along the blood vessels. Bone deposits in an early stage involve the upper third of the femur, but the lower half of the humerus. They then occur mostly in that district of the bone towards which the nutrient artery of the shaft is directed. More closely examined, this contention loses much of its force. The seat of election for cancer of the femur is the great trochanter; of the humerus it is at the deltoid insertion. One would rather imagine, if the process were embolic, that the seat of election in the femur should be in the neck near the epiphyseal line, and not at a point distinctly lower down. Again in the humerus, when the nutrient artery enters below the mid-point of the bone, the line at which fracture is most often found—the deltoid insertion—lies above the nutrient foramen and not below it, as would be required in the embolic theory.

"If bone deposits are disseminated by the blood stream it seems reasonable to argue that cases in which they occur should show pulmonary metastases with especial frequency. As a matter of fact deposits in the lungs were only present in 4% of 37 cases showing extensive bone deposits, while pulmonary metastases are recorded in 26% of an entire series of 329 cases.

"The weightiest argument against blood infection as a cause of bone deposits lies in the entire escape from metastases of the tibia, fibula, radius, ulna and bones of the hands and feet. These bones are just as liable to embolism as the femur or humerus, probably more so, on account of their greater nearness to the periphery of the circulation, and yet metastases in them are of the rarest occurrence."

Observation has proved that the growth does not spread primarily along the skeleton by continuity and does seem to indicate that the extension is by way of the fascial planes through the delicate network of lymphatics which are known even to accompany blood vessels.

When we consider the process of invasion of the humerus and femur, granted, they are invaded via the lymphatic plexus of the deep fascia, the first attack should be directed on that point at which the bone lies nearest to the deep fascial lymphatics, and therefore on that point at which the bone comes nearest to the cutaneous surface. Moreover, in the case where a bone is provided with two or more subcutaneous areas, the seat of first attack, according to the

view of centrifugal spread, must be that area nearest the trunk. Thus the point of invasion in the femur should be, and in point of fact is, the base of the great trochanter and the adjoining part of the linea aspera. The point of invasion of the humerus should be, and actually is, relatively much lower down, at the deltoid insertion, since the whole of the upper half of the humerus is well clothed with muscles.

Centrifugal extension, therefore, explains in the humerus and femur the peculiar seats of metastases better than embolic infection via the blood stream.

Bones distal to the elbow and knee escape simply because the patient dies, almost invariably, before the growth has spread along the deep fascia far enough to reach them.

Regions Affected. A fact of particular interest is that bone metastases rarely ever occur in areas not commonly invaded by subcutaneous nodules. These occur in all areas of the body proximal to the elbows and knee joints.

In relation to this phase of the subject the following table is of interest:—

	Bone.	No. Cases	Percentage
Bones lying wholly or partly within the area liable to subcutaneous invasion.	Sternum	30	9
	Ribs	28	8
	Clavicle	5	1.5
	Spine	12	3.6
	Cranial bones....	9	2.7
	Scapula*	1	.3
	Femur	14	4.2
	Os inominatum..	0	0
Bones lying below the area liable to subcutaneous nodules.	Humerus	9	2.7
	Radius	0	0
	Ulna	0	0
	Tibia	1†	.3
	Fibula	0	0
	Patella	1†	.3
	Bones of hand... 1	.3	
	Bones of foot....	0	0

From 1872-1901 at the Middlesex Hospital there were 329 autopsies on cases of mammary cancer. Excluding cases where the only bones to which cancer had extended were the sternum and ribs, there were 37 cases in which the bones were the seat of secondary deposits or spontaneous fracture. When the cases of sternum and rib involvement are included, there were 73 cases, or a percentage of bone involvement of 4.5.

In general, autopsy records give reliable information only in regard to frequency of metastases in those bones which are subject to spontaneous fracture, with the exception of the vertebral column. Other bones are rarely examined as a routine. Hence statistics of recurrence may show too low a percentage. For this reason it is probable that the escape of the scapula and pelvic bones is almost certainly apparent only. The absence of records of spontaneous fracture in the distal bones shows that the escape from

cancerous invasion is real and not merely apparent.

Bones Most Commonly Affected. The liability of a bone to cancerous metastases increases with its proximity to the site of primary growth; thus the sternum and ribs are affected in about the same number of cases and more frequently than any of the other bones. The spine, femur, humerus, and cranial bones come next, the clavicle forming an exception to the general rule. Bones distal to the knee and elbow escape invasion except in the rarest instances. Halstead had no cases of involvement below the knee in his large series.

In the femur the deposit is usually present in the upper third of the bone, most often a little below the base of the great trochanter. Thus the point of election for spontaneous fracture in breast cancer does not coincide with the usual position of senile fracture of the femur, which is across the neck, nor with the point of the entry of the nutrient artery. There is strong clinical evidence that the great trochanter is the point of first invasion. Of eight cases showing unilateral fracture of the femur, the fracture was on the same side as the primary growth in six cases, and on the opposite side in only two cases. In 329 autopsied cases there were found 6 in which one or both humeri were the seat of deposits. In five of these cases attention was directed to the bone by the presence of fracture. The deltoid insertion was the site most often involved; the process extending upward and downward from this point by the medullary canal.

The infection may occur months or years after the removal of the primary growth, as instanced in the first part of this paper.

The character of the secondary tumor always corresponds to that of the primary growth. The bone lesion is never primary.

Histo-Pathology. Carcinomatous infiltration of bone causes diffuse lacunar absorption, rendering the bone soft and easily bent or broken. There may also be present at the seat of infiltration a tendency to the development of new bone tissue. This condition has been described as osteopathic carcinosis. The invasion of the marrow, in other words, leads to a low grade osteoporosis, called by Von Recklinghausen "osteomalacia carcinomatosa," which practically never penetrates or extends into soft parts or joints. There is gradual softening and thinning of bone, but rarely an osseous tumor large enough to be detected clinically. Tumors are more often found in the skull than elsewhere. Skeletal deformities other than local changes are rare. Unlike sarcoma, it is not the tumor which first calls attention to the disease. Spontaneous fractures are not as common as might be expected.

The radiographic literature on this subject is meagre. There appears no systematic report on these cases, there being only scattered mention of individual cases.

Pfahler reports a marked absorption of lime salts, that the areas are more sharply defined

* This bone is seldom the seat of spontaneous fracture and is, therefore, overlooked at autopsy.

† This was a rare case in which there was ankylosis of the knee and continuous extension of the process downward from the femur.

than in syphilis, osteomyelitis or tuberculosis, but more irregular in outline than bone cysts. There is no marked periostitis.

Union after fracture has been reported in 2 cases.

The most remarkable feature of multiple metastases is that they have been known to undergo spontaneous involution.

Frequency. Kaufmann finds that bone cancer is most common after cancer of the breast, thyroid and prostate. The occurrence in prostatic cases being about 16%. Cabot believes that the frequency may even be greater than this.

In cases of elderly men with unexplained pain in the back or legs the prostate should be examined for malignancy. Cabot (in a personal interview) mentions several instances of this kind. The bone involvement in malignant disease of the prostate is early and must be reckoned with in estimating the chances of cure, even if the neoplasm is entirely extirpated.

Fischer-Defag found metastases in the spine or femur in 25% of post mortems on cases of cancer of the prostate in the Dresden Hospital.

After breast amputation metastases in the spine are quite common, especially when the disease is the atrophic scirrhus type.

Kaufmann's figures are interesting. In 138 cases he found the lumbar vertebrae involved in 27, the dorsal in 19, femur in 23, ilium 4, ribs 19, sternum 12, and skull in 11. It is not uncommon for more than one bone to be involved, sometimes as many as six or seven.

Leutinger's cases showed 14.5% in the spine, 7.6% in the extremities and 2% in the skull. More modern statistics show as high as 25% in the vertebrae, 20% in the femur and 18% in the ribs. Blumer found 90% of thyroid metastases in women. A peculiarity of this form of the disease being that the thyroid resembled the ordinary goitre without exophthalmus and in no way suggested malignancy. No obvious thyroid enlargement is found in at least 25% of the cases; 38% of thyroid metastases occur in bones of the face and cranium, 10% in the vertebrae, 10% in the femur, 9% in the pelvic bones, 7% in the sternum and 5% in the humerus. Of course all these figures are relative but tend to give, by their practical uniformity, a very good general idea of the relative frequency of these metastases in different regions.

Blumer, analyzing 45 cases, found spontaneous fracture in 24% and spinal symptoms in 13%. Blumer also, contrary to Handley's rule, found as many as 1.4% in the hand and foot. An analysis of his cases reported fails, however, to discover the case histories of any in which such metastases occurred. We know that such metastases are very rare. Paget found no such metastases in 650 cases. Osler reports 1 case of fusiform metastases in the right thumb, followed shortly by involvement of the right clavicle and then the left tibia and ankle. But this was one of the unusual cases of widespread generaliza-

tion mentioned in their report by Brunon and Firbut.

Symptomatology. There may be none. The only characteristic symptom of this disease is pain, generally rather continuous, very severe, generally described and diagnosed as, or mistaken for, myalgia, lumbago, sciatica or rheumatism. Local tenderness over the site of the growth may be present, but is the exception rather than the rule. Spinal paralyses are rare, considering the frequency of involvement of the vertebrae; this is probably so because the disease attacks the bodies first. Skeletal cancer may offer the first evidence of primary neoplasm elsewhere, many cases of cancer of the breast and prostate not being discovered till x-ray shows tumor formation when submitted for diagnosis of a spontaneous fracture. This is well illustrated by one of Wharton's cases. A woman while walking in her room felt her left leg give way under her. Examination showed fracture and tumor of the middle third of the left femur and unsuspected and inoperable cancer of the left breast. Cases of this kind could be multiplied many times.

Wharton cites one case of metastases in the left clavicle 5 months after removal of the left breast. The clavicle was fractured while the patient was turning in bed. A marked tumor developed at the site of fracture before death, which occurred two months later. Also another case in which both femora were fractured while in bed six months after removal of the breast. This patient also later developed a tumor in the right humerus and one in the left parietal bone. Multiple tumors are, however, rare, as the patient more generally succumbs to the ravages of the disease before many metastases have developed. Cabot instances many cases where unexplained pain in the back was cleared up by rectal examination showing malignancy of the prostate. Braekett, seeing many cases of obscure back pain, often finds malignancy primary in the breast or prostate. Bony involvement, where there is tumor formation or acute localizing pain, may be mistaken for aneurysm, especially when it is located in the sternum or cranium. In the latter situation there may be signs of cerebral compression demanding surgical relief.

The relative obscurity of the spinal type demands further analysis. Spontaneous fracture and well marked kyphos may be present. Certain of these cases before fracture have the excruciating pain characteristic of nerve root pressure and are the most distressing of all types. This may later develop into a paraplegia, called by Cruveilhier years ago "para plegia dolorosa." The dorso-lumbar region is the part most commonly affected. The lesion may be high up in the cervical region and a quadruplegia result. There may be herpes zoster at some stage of the process. During the neuralgic stage these unfortunate patients are often treated as neurasthenics. There have been instances in which the onset, instead of being gradual and suggesting

compression of the cord, is very sudden and is like an acute myelitis of degeneration or infectious origin. The most expert neurologists have been led astray by these acute cases. In the chronic cases a visible tumor or spinal deformity is the exception rather than the rule. Osler reports a case of recovery after a complete paraplegia. This is extremely rare.

Summary. A review of the foregoing facts reveals the following facts of importance in regard to metastatic bone cancer:—

1. Metastasis takes place probably by centrifugal spread along the lymphatic plexus of the deep fascia in most cases.
 2. Bone metastases occur almost entirely in the areas of the body subject also to skin nodule metastases, *i.e.* everywhere proximal to the elbow and knee joints. Bones distal to these joints are very rarely involved.
 3. Metastases are more common after cancer of the breast than any other organ. The prostate and thyroid being the next most common. (Hypernephroma of the kidney is not considered in this series.)
 4. The liability of a bone to cancerous invasion increases with its proximity to the site of the primary focus. Thus the sternum and ribs are affected about equally and more frequently than any other bones. The spine, femur, humerus, pelvic and cranial bones come next.
 5. The character of the secondary lesion always corresponds to that of the primary growth.
 6. The frequency after cancer of the prostate may be as high as 25%.
 7. The vertebrae are the favorite seats of attack in scirrhus of the breast.
 8. The percentage of vertebral metastases is nearly 25%.
 9. Spontaneous fracture is present in about 24%.
 10. Pain is the only characteristic symptom.
 11. Visible or palpable tumor is rare, while spontaneous fracture is quite common.
 12. We may set down the following points as diagnostic aids: A fracture of a long bone occurring as a result of trivial injury should immediately suggest the possibility of bone metastases and lead to careful search for the primary new growth. In all cases of painful paraplegia a neoplasm should be suspected.
- A diagnosis of primary bone tumors should never be made without very careful examination of the abdomen, mammary glands, prostate, and thyroid for malignancy. It is rare that careful search will fail to reveal the primary focus.

CORSETS, PTOSIS, AND SACRO-ILIAC STRAIN.

BY ROBERT M. GREEN, M.D., BOSTON.

[From the Gynecological Clinic of the Boston City Hospital.]

IN the issue of the JOURNAL for Jan. 2, 1913 (Vol. clxviii, p. 12), I published a brief paper¹ on "The Role of Ptosis in Gynecology." Much has been written, both before and since that time, on this most important topic. Of particular value is the recent work of Kellogg² and Williams.³ Yet despite the contributions of many authors, the subject remains in large part neglected or not understood. Unrecognized or untreated ptosis is still the commonest cause of gynecologic failure.

The following observations represent the conclusions of my experience in the gynecologic clinic of the Boston City Hospital, and in private practise. If they seem too strongly stated, it is not because I am engaged in special pleading, but because I have been impressed with the frequency of improper corseting and consequent ptosis in women of all classes, and convinced of the importance to both practitioner and patient of recognizing and correcting this condition whenever it occurs. As vigorous an educational movement is needed among physicians and among the public on the subject of ptosis as on that of uterine carcinoma from neglected cervical laceration. The latter may cause death, but the former may cause lifelong discomfort and disability.

A majority of women, from various causes, suffer from ptosis of one or more of the abdominal viscera. Such ptosis may complicate and aggravate various pelvic diseases, or may simulate them with a variety of symptoms. As most such female abdominal ailments are referred to the pelvis, such cases usually come to the gynecologist, who may err lamentably in his diagnosis and treatment, if he is not alert to detect ptosis in its various forms. Many a patient has been treated in vain for supposed pelvic disease when ptosis was her sole ailment, and many another has failed of the full benefit from effective treatment of her pelvic condition when her coexistent ptosis has been unrecognized and untreated. Hence the subject of ptosis is of vast importance not only to the success of the practitioner but to the welfare of his patients.

Men do not often have ptosis. The principal causes of the preponderating occurrence of

this condition in women, in the order of their increasing importance, are:—

1. Primarily poorer muscular development of the abdominal wall.

2. Childbearing, which stretches the abdominal wall and then leaves it relaxed and unsupported.

3. Improper corseting, which compresses the viscera downward and prevents normal use of the abdominal muscles.

The first two of these causes are to be regarded as predisposing; the last is the determining cause in practically all cases. Savage women rarely or never have ptosis. Essentially ptosis is a costume deformity. Peasant women and others who never wear corsets may have ptosis from fastening heavy skirts tightly around the body above the level of the umbilicus. Doubtless if a generation of girls could be brought up with wholesome physical development and really hygienic costume, ptosis would disappear, except perhaps in multiparae and in the aged. This millennial condition, however, is hardly at present to be expected. Until, therefore, the good sense of women makes genuine costume reform a reality, some sort of corset will be worn by the majority; and since one must be worn, it should at least be proper rather than vicious in type, in order to prevent and relieve, rather than cause and exaggerate, ptosis.

The corset worn by the majority of women is a relic of Victorian barbarism. It laces behind, is applied in the standing posture by hooking from above downward, and, being much too high, encroaches on the lower ribs, impedes the action of the diaphragm, and applies its maximum constriction about the epigastrium. It tends to produce the typical matronly figure that was the ideal of feminine beauty in the age of Jane Austen, crinolines, and the steel-plate engraving lady. It is absolutely and unutterably pernicious.

All corsets may be roughly classified in two groups, those that lace only behind and those that lace in front. The former are all bad. The latter may be good, provided that they have certain other qualifications. The essentials of a good corset are as follows:

1. It should lace in front.
2. Its lower border should come to the level of the trochanters and no lower.
3. Its upper border should not reach high enough to touch the breasts; it may be much lower.
4. It should be of suitable size.
5. It should be as lightly boned as possible.
6. It should be equipped with garter straps.

Moreover, the good corset, to be of any value, must be properly worn. A bad corset intelligently applied is better than a good corset improperly applied. The usual method of putting on a corset in the standing posture, hooking it

from above downwards, is absolutely wrong and productive of the worst possible results. The essential points in the technic of properly putting on a good corset are as follows:—

1. The corset should be loosely applied while patient is lying down with a small pillow under the sacrum and hips, and none under the head. By this means gravity allows the viscera to assume approximately their normal position.

2. The garter straps should next be fastened to the stockings, to prevent the corset from sliding up during and after application. It is best that there should be three straps to each leg, one on the ventral, one on the lateral, and one on the dorsal aspect of each thigh.

3. The corset should now be laced from below upward, the lace being tied in three places, the first very tightly at the level of the linea semicircularis, the second moderately at the level of the umbilicus, the third very loosely at the top of the corset. The lowermost lace should be at the level of the symphysis.

A correct corset, thus applied, supports the viscera from below upward, and does not permit them to sag towards the pelvis, when the patient rises. On the contrary, the figure remains normal, with the flat hypogastrium and the full epigastrium seen in well-developed men. In other words, a good corset, properly applied, does the exact opposite of the bad corset, wrongly applied, which with the assistance of gravity forces the viscera down towards the pelvis and imprisons them there, at the same time constricting the lower ribs and diaphragm so that normal respiration is impossible. The supposed physiologic differentiation of male and female respiratory type, the former diaphragmatic, the latter thoracic, is no true physiologic sex distinction at all but merely represents the habitual corset disability of the woman.

A good corset, properly applied, then, will in most cases correct ptosis and relieve its symptoms. Broadly speaking there are two general types of ptosis:—

1. Enteroptosis (and gastroptosis), seen chiefly in short, plump, rotund women with hollow backs and the hyperfeminine type of figure, and in multiparae.

2. Nephroptosis (much less common), seen chiefly in tall, scrawny women with flat backs and the masculine type of figure.

In both types, the variety of symptoms produced is legion. In enteroptosis, they are chiefly sensations of weight and fullness in the lower abdomen and pelvis, constipation, flatulence, bloating, and other digestive disturbances. The diagnosis is made by inspection and percussion. When associated with any genuine pelvic disease enteroptosis will always exaggerate the symptoms of the latter. It may maintain or be the sole cause of retroversion. This type of ptosis, as occurring in heavier women, is also often associated with sacro-iliac strain, to which they are more

liable on account of their greater proneness to flat-foot. This predisposition to flat-foot is partly due to the greater disproportion of their weight to their musculature, partly to the villainous shoes which most women wear. Like ptosis, the flat-foot, sacro-iliac complex is a postural costume deformity.

When sacro-iliac strain or flat-foot or both are associated with ptosis, there are added the symptoms of backache, muscular lameness in the back and calf, and often pain in the knees. The diagnosis of flat-foot may readily be made by inspection; that of sacro-iliac strain by eliciting tenderness over the joint and by testing the motions of the spine and pelvis for pain and limitation. The treatment is simple. Except in acute stages, the same corset that corrects the ptosis will relieve the sacro-iliac strain by splinting the pelvis. When flat-foot coexists it should be corrected by substituting for the usual narrow-toed boot with high, bevelled heel, a broad-toed shoe, with low, flat heel. It is often advantageous to employ for a time the Thomas sole and heel to throw the weight towards the lateral border of the foot. The patient should also be taught to walk with the toe pointing almost straight forward. Acute cases of flat-foot and sacro-iliac strain are both best treated by rest and strapping. The flat-foot, sacro-iliac, enteroptosis complex is exceedingly common in multiparae, in whom repeated pregnancy has loosened the sacro-iliac joint, and stretched and weakened the entire musculature.

Nephroptosis, as has been stated, is less common, but almost equally important. Its symptoms are chiefly pain in the side, flank, and back, radiating to the groin, often referred to the pelvis. The diagnosis is made by palpating the sensitive kidney, which descends abnormally with respiration. The treatment is to apply the same type of corset as for enteroptosis. Sometimes it is necessary to employ also temporarily a reniform pad applied under the costal border, but more often the corset alone corrects the condition by holding in the epigastrium the intestinal coils upon which the kidney should rest and which normally support it in position. Nephroptosis predisposes to infection of the kidney, and the much greater frequency of pyelitis in women merely represents their frequency of nephroptosis. Hence the importance of early correcting nephroptosis to prevent pyelitis as well as to relieve symptoms.

Ptosis, then, with its protean manifestations, should always be looked for by the gynecologist. It is usually easy to detect and satisfactory to treat. In obscure cases, use should be made of the bismuth meal and enema and x-ray to determine the exact conditions. Unrecognized or untreated ptosis, with its sequels, is probably the commonest cause of feminine disability and gynecologic failure.

A CASE OF OSTEOMYELITIS WITH NECROSIS OF THE ENTIRE FEMUR AND SPONTANEOUS FRACTURE TREATED BY A HIGH AMPUTATION, LEAVING A BONELESS YET PRACTICAL STUMP FOR THE ATTACHMENT AND WORKING OF AN ARTIFICIAL LIMB.*

By ALBERT H. TUTTLE, M.D., BOSTON.

Miss Florence P., at the age of sixteen, while skating Jan. 18, 1908, fell on the ice, violently striking her left knee. She continued to skate during three days following the accident, when her "leg gave way" and she could hardly get home. She took to her bed because she could not use her limb.

Her entire leg was swollen, red and glossy. Dr. A. was called and, not knowing there had been an accident, diagnosed the case as rheumatic fever. An abscess formed, pointed and broke, on the inside of the knee at the end of the fifth week, and another three weeks later, higher up. Spicules of bone came away with the discharge of pus.

In November, 1908, she entered a public hospital.

Dr. B. took an x-ray, laid the leg open, and found new bone formation. Dec. 31, Dr. B. opened the leg again and inserted bone grafts. The wound broke down and a second attempt at bone grafting was made in January, 1909. The wound was then treated with *bovine* and healed, leaving four sinuses. These were laid open in March, April and May for curettage and better drainage. A course of opsonic treatment was given during a period of ten weeks, and the patient left the hospital in June, after six months' treatment.

The limb was encased in splints, and she moved about, but only in a wheel chair, during the next five months. She discarded the wheel chair for crutches in December, and the crutches for a cane in January, 1910. The four sinuses continued to discharge pus, and from time to time there was swelling of the knee, the opening of which was repeatedly enlarged for better drainage. During the summer of 1910 she was able to do away with the use of the cane. Labor Day an abscess the size of a hen's egg, and of purple color, formed on the knee, and was opened.

As the case continued without improvement, in October, 1911, the patient consulted Dr. C. He sent her to another public hospital, took an x-ray of the case, and on the thirteenth operated for the removal of dead bone in the shaft of the femur.

She left the hospital in two weeks and Dr. D. took charge of the case at her home. Within three weeks of her return, an abscess formed and broke, discharging a quantity of pus and a steel chisel point, the size of a little finger nail.

The case grew worse, with more pus, increase in pain, and swelling of the knee. Again the patient took to her bed, and in January, 1912, went back to the hospital.

Dr. C. performed a second operation, and put the limb into a plaster cast. Much suffering followed, and in two weeks this cast was removed and a larger

* The history of this case was prepared from a statement of the patient, who was shown at a meeting of the Surgical Section of the Suffolk District Medical Society, February 3, 1915.

one substituted, which enclosed part of the body. In spite of great suffering, she wore this cast for two weeks, when it was removed, and replaced by wooden splints.

About two weeks after the application of the wooden splints, the patient experienced severe cutting pains in the limb, and an examination of the wounds showed the ends of a broken femur projecting through one of the openings.

The desperate condition and sufferings of the patient at this time was manifest in the conduct of her attendants.

Dr. D., an assistant of Dr. C., resigned from the case, saying he was too busy to give her proper attention, and Dr. E., an interne, who took his place with the dressings, after two or three weeks' care, told the patient it pained him so he could not bear to do it any longer. He said the case was getting worse, and that if the pus got into her system there would be no chance for her life. He further advised her to pluck up courage and have the leg amputated.

As a result of the interne's advice, the patient asked Dr. C.—this was Friday—if the leg would have to come off, and he answered, "Certainly not. I am going to save it." The following Monday, however, he said it must come off right away, but his prognosis was so unfavorable that the patient would not consent to the operation. That night her sister, in spite of protests, had the patient removed to a private hospital (Hillside, Dorchester).

The following day, Mar. 26, 1912, I was called in and operated immediately, with the assistance of Dr. Harold V. Andrews. The operation consisted of an amputation through the upper third of the thigh, splitting of the stump and the complete removal of the proximal fragment of the broken femur, which was found to be necrotic throughout its whole length, the bone being easily removed by incising the capsule and severing the ligamentum teres.

The perfect recovery of the patient was due largely to the recuperative powers of her age, and the case is of special interest, as demonstrating the value of a six-inch fleshy, boneless stump for the attachment of an artificial limb. The limb used by the patient is attached to the body by a simple belt strap, and further secured by short stump straps. It is entirely devoid of cumbersome body armor or shoulder straps.

With this artificial limb and a cane, the patient is able to walk quite extensively without assistance.

REPORT ON OBSTETRICS.

By ROBERT L. DENORMANDIE, M.D., BOSTON.

AND

By JOHN B. SWIFT, JR., M.D., BOSTON.

REVIEW OF THE LITERATURE ON TWILIGHT SLEEP.

THERE has been so much misconception in regard to scopolamine-morphia anesthesia in obstetrics, or so-called twilight sleep, that it seemed

advisable to go over the authoritative literature on the subject. The following article is a review of the chief important articles which have appeared since 1902, when the first work of scopolamine-morphia anesthesia in obstetrics appeared.

In November, 1902, v. Steinbuechel¹ of Gratz first reported the use of the combination of scopolamine-morphia in obstetrics. He then reported one case as a preliminary report of his further article, which appeared in 1903. In this first report Steinbuechel spoke of the peculiarly antagonistic influences of the two drugs on the human organism and warned us then of the unknown influence on the fetus of even very small doses. He used .0003 gm., or 1/200 gr. of scopolamine hydrobromicum (Merck) and .01 gm. or 1/6 grain of morphia muriate. He waited two hours before he gave the patient the second dose, which was half the original dose. His second article contained the report of twenty cases, in sixteen of which the results were good, three medium and one a failure. There was no disturbance of the third stage of labor. One case developed marked excitement. Seventeen of the children were born alive and in good condition. Three were lost, but in no way could scopolamine be regarded as the cause.

In 1904 Weingarten² of Giesen and Wartapetian³ at Jena reported forty-five and twenty cases, respectively. Reining⁴ followed Wartapetian with thirty-six cases. The results were variable, both as regards the relief of pain for the mother and the condition the baby was born in.

Pusching⁵ reported in 1905, 62 cases, in which he said the method was a "treat to the woman." He used .0005, or 1/120 gr. of scopolamine, combined with the same dose as before of morphia, gr. 1/6. He observed no change in the strength of the pains and no danger to the fetus or that the drugs had any accumulative effect. Up to this time he is the writer who favors most highly this method.

In February, 1906, Gauss⁶ reported three hundred cases from the Freiburg clinic, and in 1907 appeared his results of the first thousand cases. The development of this form of obstetric anesthesia is due entirely to Kronig and Gauss at their Freiburg clinic, and in order to know what their technic is, their published papers are of the greatest aid. Gauss has written in more detail than Kronig.

Gauss says for a method of anesthesia to be useful in obstetrics it must not disturb the pain activity, the abdominal pressure, the placental stage, the lactation or the puerperal involution, and finally, it must not be harmful to the mother or to the child, whose functions must be all right the first few weeks of life.

The technic⁷ is as follows:

When the pains in a primipara are well established and coming every four to five minutes, or in a multipara every five to seven minutes and

last thirty seconds, an injection of .0003 gm. or 1/200 gr. of scopolamine is given and then .01 gm. or 1/6 gr. of morphia. An effect is usually seen in from 15 to 30 minutes. Three-quarters of an hour after this injection the patient's memory is tested by asking some simple pertinent question; if she remembers and answers correctly a second dose of scopolamine is given, but one-half the first dose. Morphia is not repeated. If the memory is lost, the second dose of scopolamine is held off until by further questioning it is seen the memory is returning. In the majority of cases the desired condition of amnesia is reached with two and a half doses. (Throughout this paper we regard the standard dose of scopolamine as .0003 or 1/200 gr.). This condition of amnesia is reached slowly by repeated doses of scopolamine, given at from one to three-hour intervals. A fresh injection is given only when the memory test proves the object shown thirty minutes before to the patient or the question asked has been retained in her memory. Throughout this time the memory test is constantly applied and Gauss warns not to keep asking the same questions over and over again, but to change now and then, and to make use of the various happenings of the labor, such as the rupture of the membranes or vaginal examinations.

As the patient comes under the influence of the drugs she sleeps between the pains, only to rouse and groan or cry out at the height of the pain.

Gauss has no desire to keep patients quiet throughout the labor. He specifically warns not to attempt to narcotize the patient so much that she will not respond to the pains. The phrase he constantly uses is that the patients perceive the pains but do not apperceive them. In other words, they respond to the pain, cry out and move about, but they do not store these impulses up in their brains to make much of at a later period. Upon this memory test, carefully and diligently carried out, Gauss says the entire method stands or falls. Gauss insists that if physicians do not carry out the details of the technic as advised by him then this method of twilight sleep must not be condemned if the results do not correspond to his.

Besides the memory test there are other signs which show the patient is under the influence of the scopolamine, but as they are of no such value as this one fundamental one, we simply allude to them,—the appearance of the Babinsky reflex, the dilatation of the pupil and motor incoördination. In order to have uniformly good results the patient should be guarded from the influence of sensory impressions, such as loud noises and strong light. To do away with such disturbances, Gauss places dark glasses or a towel over the patient's eyes and fills her ears with cotton dipped in oil. Certain of the writers who have had not as good results as Gauss make light of these precautions. Kronig,¹⁰ how-

ever, feels that because Leopold in Dresden and Bunn in Berlin have such large clinics and cannot obtain the quiet that is necessary their results are not good. Nurses and physicians trained to follow the memory test accurately are also most essential for the carrying out of this method.

Up to within a relatively short time it has not been possible to obtain a uniformly good preparation of scopolamine. Whether the reason was that the scopolamine which first was on the market was not true scopolamine or that scopolamine is unstable, we cannot say, but we are inclined to think both reasons were present. The pharmacologists say that scopolamine and hyoscyne are chemically of the same formula, but it is now well established that the action of the two drugs differ. The unstableness of the drug Gauss recognized early, and warned physicians against using it if the solution showed any cloudiness or flocculi on shaking. Because of the instability and the consequent poor results which appeared, Straub after experimentation found that if mannite were added to the scopolamine it remained stable. Siegel, working at Freiburg, has found such a solution to remain stable, at least a year and a half.

Not only has the preparation used been variable, but the effect on any individual patient is always at first unknown, even at the present time, and that is one of the reasons why in inducing amnesia the doses must be small and given slowly. There are certain side effects which not uncommonly follow the giving of scopolamine, and whether one thinks them of much or little importance, depends upon whether he favors the method or not. The reddening of the face certainly is not alarming. The thirst is not infrequently most annoying and to overcome it water is urged on the patient at short intervals. The motor excitement at times is tremendous, necessitating several nurses to hold the patient in restraint. Fortunately, this is not a common side effect but as yet no one can foretell which patient will show it.

The hallucinations, the incoherent mumblings, do occur, but Kronig¹¹ states that "these are of no material importance, so long as the relations of the mother do not remain in the room, for these states of excitability make an unpleasant impression on the family. In consequence of this, we only carry on the method of 'twilight sleep' in cases where the relations promise to be out of the room during the whole time of the birth."

When Gauss reported his first three hundred cases he said that he had used this twilight sleep in 62% of all the cases that came to the clinic, and some time later Bernti,¹² reporting further cases from the Freiburg clinic, said it had been used in but 64.58% of all the cases entering the clinic. We have not found other figures of the frequency that this method may be used. Freeland and Solomons¹³ at the Ro-

tunda Hospital began their investigations in the fall of 1908 and yet it was not until the fall of 1910 that they could report on 100 cases. All the other writers give the number of cases but in no instance do they state the percentage on which it was possible to carry out this technic.

Gauss claimed that the course of labor by this technic is in no way interfered with, that the operative frequency is not increased and that the third stage is in no way altered from the normal.

Shortly after Gauss reported his first series of cases, other obstetricians took up the method and Hocheisen¹⁴ was among the first to report cases and he was not in favor of its use. He found more than 70% of his patients showed some of the unpleasant side effects such as vomiting, marked headache and dizziness, excessive thirst, restlessness, delirium and hallucinations. He notes that the women did not remember any of these effects but the lay persons seeing it were much upset for they expect a quiet physiological sleep. He claimed the birth was lengthened in 50 cases, 5 times atonic post-partum bleeding and 15 times marked retardation of the involution of the uterus occurred. Eighteen per cent. of the babies were born in a state of oligopnea and 15% in asphyxia. One child died during birth and three shortly after birth, yet he admitted that scopolamine could not be blamed for these deaths. He advises the conscientious physician to keep his hands off twilight sleep until favorable effects have been assured.

This article of Hocheisen was very soon answered by Gauss⁸ with an analysis of his first 1000 cases. In the course of this paper Gauss showed that Hocheisen had failed to use the memory test and had used a solution of scopolamine which had broken down as shown by a fine deposit with a milky appearance when shaken. He used this same preparation on ten patients and obtained poor results. Hocheisen's paper, coming as it did from Bumm's clinic, made a strong opposition to the quick taking up of this method. In this series of 1000 cases there was no maternal death due in any way to scopolamine. There was no increase in the percentage of post partum bleeding. In 363 cases the amount of blood lost was measured and the average was 277.7 grams which, according to von Winekel's table is well within the physiological loss.

The third stage was completed spontaneously or by a very slight pressure on the belly in 51% of the cases, while pressure or slight Cr  d   accounted for 48.1%, manual extraction .4%, and manual extraction after a Caesarean section .5%.

The maternal morbidity is no different with this method than with any other. It was claimed that inasmuch as the drug was excreted by the kidneys, damage would be done the kidneys, but careful examinations by Gauss of the urine of 100 women showed this to be untrue.

From a careful analysis of the length of labor in these 1000 cases there is a slight lengthening of the labor. Kronig says the average length of labor has been increased but half an hour. The opponents, on the contrary, find there is a decided lengthening of labor due chiefly to the prolongation of the second stage. This prolongation of the second stage, the opponents say, is because the women are unable or will not bear down in order to expel the baby. Gauss says that when a patient will not bear down the proper technic has not been followed; that the belly pressure is done away with because too deep narcosis has been obtained through lack of observing the memory test. He argues that if the condition of amnesia only is present, the patients bear down better because the pain is not appereceived. Writers report several cases where twilight sleep has been maintained 40-50 hours with no apparent detriment to the mother or child, and as much as .00675 gms. (roughly 1/10 grain) of scopolamine has been given.

In the first 500 births the operative frequency was 9.68%, while in the second it dropped to 4.95%. In Fehling's clinic the operative frequency without seopolamine was 5.29%. In 163 private cases Gauss stated that "relief forceps were not used once, because," he says, "we are independent of the crying and praying of the mother because we know the patients are in amnesia because of correct twilight."

We must all admit that this is a very low operative frequency when compared with our own percentages. We realize that Bokelmann's statement that 40% of his cases showed operative deliveries, 20.8% of which the only indication was the relief of pain, is much nearer our own results than are those of Gauss.

This difference in operation frequency has been made much of by Gauss and some of the lay writers. Its importance lies only in the fact that an appeal is made to the woman's temperament. If sepsis and morbidity, fetal or maternal, follow operative deliveries, then of course Gauss' claim that the operative mortality is lowered is an excellent point in favor of scopolamine and morphia anesthesia. But we feel that the operative morbidity should be no different in simple low forceps work than in normal delivery, and the time saved to the mother is a very appreciative point. If we assume that the operator will have bad results with high maternal and fetal morbidity, then Gauss' claim for a low operative mortality is important. That presupposes poor obstetricians, poorly trained men, and in that class of cases there is no question but that the fewer operations that are done the better for the patient.

Gauss has given no figures on the frequency of perineal tears, but the impression one gets from reading the articles is that the tears are of less frequency and of less severity because of the complete and slow dilatation of the birth

canal. Beruti, however, in 600 cases had perineal tears 88 times or nearly 15%.

Lactation period shows no harmful effects according to Kronig, Gauss or Beruti. Though all the writers are practically agreed that scopolamine is not dangerous to the mother, the result to the child is not so favorable. In about 25% of all births with scopolamine the babies show a definite alteration from the normal breathing. That is, they present a picture of either oligopnea or asphyxia, the former appearing in from 15 to 20% of cases, and the latter in 5 to 10%. The other 75% of the babies are born in a normal condition and their breathing causes no apprehension. Gauss described the condition of oligopnea as the result of the drugs used, but in no way is it to be regarded as alarming. The babies breathe and cry at birth, only to relapse into motionless slumber. The heart action at first is strong, and as the breathing grows shorter the heart beat drops even to 60. As the breathing again begins, due to the stimulation of the centre of respiration by the accumulated CO_2 , the heart beats become more rapid. This cycle repeats itself, the breathing becomes steadily better, the intervals of non-breathing steadily less. When Gauss first saw this condition he made attempts to resuscitate the baby at once. Gradually he left the babies alone more and more. Several children were left absolutely alone while in this oligopneic state and the breathing was slowly but steadily established so that now Gauss puts such babies aside, feeling confident they will in twenty minutes to half an hour begin to breathe normally. In the further condition of asphyxia, apnoea, he uses skin irritation and heart massage to stimulate the child's respiration. In this condition the child is at first more cyanotic than in the oligopneic condition and later it becomes pallid. That this condition is serious cannot be denied, but it fortunately comes with careful dosage but very seldom. Gauss feels that it is the effect of the morphia on the child, and not the scopolamine, and with careful individualization of each case, the condition will not arise. Gauss at first had a percentage of 13% apnoeic children while Beruti later in 600 cases reduced this condition to 5.14%.

Beruti's analysis of 600 cases in Gauss' clinic is most favorable and we quote some of the figures.

Of 609 cases, 9 sets of twins, 602 children or 98.85% were born alive, 7 stillborn or 1.14%, and of these seven deaths, the only ones which could be laid to the twilight sleep method were two. Here it was found that aspiration of amniotic fluid had occurred. But this happens when twilight sleep has not been used. Those in favor of the Freiburg technic claim this depressed condition of the child's centre of respiration makes only for the good of the child, as it prevents, to a great extent, all premature inspiratory efforts.

That this condition of oligopnea is not very

dangerous to the child must be admitted when one realizes how many thousand cases have now been delivered under this method, surely with no higher mortality than without it. It is difficult really to determine the true percentage of deaths that may be laid to scopolamine. There are so many causes which may influence the ultimate real cause of the death, that the relation scopolamine bears to the death is oftentimes minimized or exaggerated, depending upon whether the writer favors or is hostile to the Freiburg technique.

What are we to expect from this technic? Can we confidently tell each and every patient that now she may have her baby without the slightest pains?

From reading Gauss' articles it is clear that the stopping of pain is not his goal or claim. The patient, if the technic is properly carried out, cries out with the pains and shows in every way she suffers. But the action of the scopolamine blots the memory of this suffering from her higher brain centers. In what percentage of cases does this ideal amnesia occur? In Gauss' first 1000 cases it occurred in 76%, while in the next 600 cases reported by Beruti, it was accomplished in only 65%. Kronig now states that this complete amnesia is obtained in 80% of the cases. Some relief was accomplished in 8.2% by Gauss and in 21% by Beruti, and in 5.6% by Gauss and in 13.6% by Beruti there was no result obtained. In other words, even at Freiburg they can use this method in but 62 to 64% of all their cases and in from 5.6% to 13.6% of these cases the drug is without results.

It is agreed that scopolamine should not be given in cases where there is a primary uterine inertia present. Gauss further avoids its use in anemias, where there is disturbance of the consciousness, high grade pelvic contractions, illness with fever, and when communication with the patient, such as deafness or inability to understand the language spoken is present. Also twilight sleep is ruled out where the labor is rapid and the termination is probable within one or two hours. Gauss and others have used this method with excellent results in cardiac conditions and in a few cases it has been tried in eclampsia but no definite conclusions have been arrived at for complication.

It is not to be expected that this method would be accepted wholeheartedly by all in the medical profession or that they would have equally good results in the cases they used the method in as did Gauss. Variable results have followed its trial by other physicians but the surprising thing in practically all the series of cases by other physicians who condemn the method is that they have strayed far from Gauss' exacting technic. One has repeated the morphia until narcosis is complete, another has ignored the memory test, others have changed the doses given without sufficient reasons.

Gauss has not changed the technic practically any recently. Beruti, in the Freiburg clinic,

tried various preparations and also the giving of veronal in combination with the usual technic.

After Straub succeeded in obtaining a uniform and stable preparation of scopolamine, Siegel, realizing that the use of the memory test intelligently was the stumbling block to the success of the method, attempted to standardize the dose—to bring it to a rule of thumb.

Siegel's¹⁵ scheme is as follows: the first dose consists of .00045 gm. of scopolamine and .03 gm. (gr. $\frac{1}{2}$) of narcophin. Forty-five minutes later scopolamine .00045 gm. is given and forty-five minutes after the second dose the third is given and this consists of .00015 gm. of scopolamine and .015 gm. of narcophin. The fourth dose of .00015 gm. of scopolamine comes one and a half hours after the third. Scopolamine is then given every one and a half hours following and at every third dose narcophin .015 gm. is given in addition to the scopolamine.

The narcophin¹⁶ referred to is a preparation made by Bohringer and Sons of Germany, consisting of a narcotin-morphine-meconate which is said to have a less marked effect on the centre of respiration of the fetus than morphia does. At the present time the majority of physicians are trying it out. When it is used it is repeated not infrequently once or twice in half the original dose—in distinction to morphia, for this is practically never repeated by Gauss.

Siegel has reported 220 cases treated under this standardization, with good results. He further altered Gauss' original technic by giving as the head was crowning, inhalations of ethyl chloride, for he found that without it complete amnesia at the most painful moment of birth was not obtained.

Of these 220 cases, 196 were spontaneous deliveries, 18 forceps, 2 breech extractions, 3 versions and 1 vaginal section, in all 24 operative cases. Eleven of these operative cases were done under inhalation narcosis, 12 under ethyl chloride and one without any additional narcosis. Eighty-eight per cent. of the cases under this form of twilight sleep had complete amnesia, 10% partial amnesia, in 2% of the cases there was no effect. In thirty-two cases an oxytocic was given to complete labor.

Gauss has not written approving this standardization of the dose. Kronig does not seem to be over-enthusiastic about it, for he says "We attempted to bring about a standardization of the dosage of this 'twilight sleep' and in the cases of women of average strength and good health the desired degree of narcosis resulted."

The reason ethyl chloride is used at the expulsion of the head is that unless the exact degree of amnesia that is correct is present, the patient has the sensation of pain. From these few sensations which Gauss has called "memory islands" the patient builds up a story of her entire labor and therefore from her point of view the entire labor has been painful and the method a failure. Rather than run the risk of these "memory isles" appearing, the ethyl chloride

or, in other instances, ether or chloroform is used.

Outside of the Freiburg clinic, this method has never taken strong hold of the medical profession. In France it has been used relatively little. In England, Croom¹⁷ reported its use in 62 cases. His results were that in the majority of cases the labor was practically painless and that with ordinary precautions the method is safe. He did not carry out the Freiburg technic. He first used 1/400 gr. scopolamine with $\frac{1}{8}$ of morphia, then increased the scopolamine to 1/100 gr. He waited until the patient was in the second stage of labor in the majority of cases. In this series no children were lost and the mother showed no untoward effects except, possibly, a tendency to post-partum hemorrhage.

Freeland and Solomans¹³ reported a series of 100 cases. Ten of these cases showed complete amnesia; in 57 there was a marked effect in the diminution of pain, in 20 the effect was fair but in 12 there was no effect. They gave the drugs hypodermically and by mouth and came to the conclusion that the hypodermic use is only preferable when the patient shows a tendency to vomit.

In their series two children born were dead following a forceps delivery after a delay in the second stage, and Freeland and Solomons say that when this occurs the cause is an error in technic and not due to scopolamine.

Freeland and Solomans do not feel that a physician must constantly be present after scopolamine has been given. They do, however, warn us that the nurse should be instructed to keep a watch on the perineum, and if the patient be asleep she should be kept on her side to prevent the possibility of the tongue falling back. In their series there were 59 lacerated perineums and forceps was done 19 times and two post-partum hemorrhages occurred.

Giuseppi¹⁸ reported the use of scopolamine in 37 cases, 26 primiparae and 11 multiparae. He used 1/100 gr. hyoseine hydrobromide and morphia gr. $\frac{1}{4}$. When the dose was repeated the morphia was omitted. The English regard hyoseine and scopolamine as identical drugs, therefore, this explains Giuseppi's use of hyoseine. Giuseppi's results were practically the same as those of other observers, though the number of cases is too few to come to any marked conclusions. At the end of his paper is a table giving in detail the results of his observations, which are very interesting.

In this review, we have not included the articles which appeared following Gauss' first articles in 1907 in this country. The results were so variable, the technic followed so different from that at Freiburg, that for our present purpose they are of no use.

Last fall articles on scopolamine-morphia anesthesia began appearing in the medical journals as the direct result of the account of the Freiburg method of twilight sleep that appeared in *McClure's Magazine*. Among the first to pub-

lish their results were Harrar and McPherson¹⁹ from the New York Lying-in Clinic. They reported on 100 cases and obtained complete amnesia in 66 cases. The successful cases were those in which the treatment was begun from three to seven hours before labor terminated. These writers did not find any increased tendency to post-partum hemorrhage, but on the contrary, thought there was less bleeding. Two babies in this series were stillborn, and one child of an eclamptic mother died, but the writers said the stillbirths were due to faulty mechanism of labor and not to the administration of the scopolamine. They do not feel that there is any prolongation of labor. The first stage showed a more rapid dilatation of the cervix followed by a delay in the advance of the presenting part in the second stage. This constant delay in the second stage resulted in an increase in the number of forceps deliveries until they began the use of pituitrin. Harrar and McPherson came to the conclusion that the method was a practical procedure, that it will abolish the "ordeal of labor" in 60-70% of the cases. The disadvantage of the method is the constant observation that is necessary and the inability to use it in private work, unless the finances of the patient permit a sufficient working staff to be present constantly.

Knipe²⁰ first reported on 41 cases, later²¹ increased this number to 101. In this latter report he obtained complete amnesia in 78, partial in 12, analgesia in 2, failure in 9 cases. In the latter cases 5, however, had but one injection of scopolamine. There was no maternal mortality due to scopolamine. There were two stillbirths, one due to failure to resuscitate a baby properly, and Knipe thinks this should have been avoided; the second a prolonged labor with a large child in a moderately contracted pelvis. Eighty-nine of the babies cried at once, 8 showed oligopnea and 2 asphyxia.

Knipe noted no difference in the third stage except in one case there was a moderate post-partum hemorrhage. Only 7 forceps were done, and from this Knipe argues that the necessity therefore for interference is not marked. He suggests that scopolamine be used guardedly in the second stage, and adds that by the judicious use of chloroform or ether amnesia may be continued.

Rongy²² reports 220 cases, and to carry out the Freiburg technic he had the assistance of a recent assistant from that clinic. In 183 cases complete amnesia with anesthesia was obtained. Seventeen cases showed anesthesia without amnesia and in 21 cases the desired effect was not obtained; 186 of the babies cried spontaneously, while 34 showed varying degrees of oligopnea. Rongy does not think the oligopnea is dangerous. Total infant mortality was 6, yet in only one case, where an overdose of narcophin was given, could the method be blamed. Twenty-three cases were terminated artificially. Rongy finds no contraindications, with the possible ex-

ception of kidney complications. He feels that the procedure is especially efficacious when cardiac lesions are present. One case developed a post-partum psychosis, who had had scopolamine, and in the same week two other psychoses appeared, yet neither of these patients had been given scopolamine.

Rongy remarked that the tendency towards engorgement of the breasts was noticeably diminished in this series. In ten patients a severe headache during the entire puerperium occurred, which yielded to medication scarcely at all, and in a number of cases the patients noticed temporarily a lack of power of concentration.

Brodhead^{23, 24} obtained good results in 35 cases out of 46, and in 3 cases he had failures. He had no maternal complications. Thirty-one of the babies cried at birth, and in the others some manipulation was necessary to make the babies breathe. He reports two cases where he thought the deaths of the babies were due to scopolamine. Brodhead says it cannot be denied that in properly selected cases, under competent supervision, this method will be proved to be safe and of inestimable benefit, but of comparatively limited use.

Humstone²⁵ reports 20 cases and Polak²⁶ 51 cases. The former obtained complete amnesia five times and partial amnesia the same. In 16 cases he obtained complete analgesia and partial in four. The babies showed slight asphyxia three times, and in one case it was marked. In the remainder of the cases the babies breathed spontaneously. He does not regard it as a panacea for painful childbirth.

The latter had no failures and in no case was there any recollection of the labor. Asphyxia was present but once and cyanosis in only two cases. Polak speaks of the minimizing of perineal lacerations because of the slow gradual expulsion. In Polak's series there were two low forceps operation. He is impressed with the wide field of usefulness that this method has, but feels that the general practitioner will hardly use it as a routine in his obstetric practice. In a symposium, "Has the Dämmer Schlaf a Place in Obstetrics?"²⁷ De Lee, Applegate, Zinke, and Hirst and Bovée all feel the method is very limited in its use, while Polak and Knipe favor its use. Schlossing, who was an assistant at Freiburg, naturally favors it and feels that the method will obliterate the fear of childbirth and have an important bearing upon race suicide.

Beach²⁸ and Hellman²⁹ favor the method, while Bandler³⁰ says that for a new method to be a permanent adjunct to obstetric procedure it must do something which is truly valuable and that, without the addition of any risks, and he adds that he is yet to be convinced that this method does this.

Such, then, is the situation of twilight sleep today from an unbiased, disinterested point of view. It has, as we have all known, a place in obstetrics. It is not the panacea that the lay

writers would have everyone believe, and neither are the physicians who do not believe in it backward, hardened individuals. All agree that the condition of amnesia is not easy to obtain, all admit that there is a definite percentage where failures occur. In only two writers have we found it stated in what proportion of *all* cases that enter a clinic is it possible to use it. These two writers, Gauss and Beruti, say they have used it in but 62% to 65% of all cases. The lay writers speak of success in 70% to 90% of the cases, carefully avoiding the statement that the method is available in but approximately 65% of all cases. Many of the lay writers speak enthusiastically of the early getting up after twilight sleep deliveries. This does not belong to the twilight sleep technic, but is a German procedure which has not been accepted by the profession at large.

The rank commercialism, which in many instances has gone hand in hand with the articles on twilight sleep, has done much harm to its acceptance. The showing of babies a few hours old, born during "twilight sleep," the printing of pictures of children some years old and their mothers, adds nothing to the effectiveness of this method. To the most intelligent such means of advertising is repellant and can in the long run be of no use. The American public have taken hold of this method, stirred on by an excellent lay writers' campaign which undoubtedly amply pays these authors.

In New York a Twilight Sleep Association has been formed, its aim being "To promote all safe and efficacious means of securing painless childbirth." In the little folder the association puts out we are given to understand that "twilight sleep" "is actually instantaneous forgetfulness of pain." It states that "the dose required for twilight sleep is smaller than for any other form of anesthesia, and the usual dangers of anesthetics are reduced to a minimum."

The authors of this folder do not enlighten the laity why the dose used is so small! Further along in the folder comes the statement that the "Freiburg Women's Hospital has the lowest mortality of mother and child of any lying-in hospital in Europe or America," and from this statement one is led to conclude that because twilight sleep is used here then twilight sleep must be the best method to use in obstetric work.

Is a low mortality necessarily a great desideratum in a lying-in hospital? We do not wish to be misunderstood in regard to this point. If a lying-in hospital is to fulfil its highest function completely it will have sent to its doors many desperate cases, and in these cases the mortality may be high, and yet the good the hospital does may far surpass the work of a hospital which has a very low mortality rate, which is proof that it has a large series of practically normal cases.

Hospitals are being opened for the sole use of carrying on this method. Department stores are

having lectures on the subject. The medical profession must investigate and come to a definite scientific answer to this wave of hysteria which is running over the country. That very soon the proper value of this technic will be established, is certain. The standing of the physicians throughout the country who are honestly trying out the rigid technic will bring about within a short time a true disinterested statement of the value of twilight sleep.

THE TOTAL NON-PROTEIN NITROGEN OF THE BLOOD IN THE TOXEMIAS OF PREGNANCY.

Farr and Williams³¹ have estimated the total non-protein nitrogen of the blood in forty cases of pregnancy. The cases are divided into four groups. Group A is composed of twelve cases of normal pregnancy or puerperium. In these the total non-protein nitrogen expressed in milligrams per 100 c.c. of whole blood, ranged from twenty to thirty, and the ammonia urea fraction from six to ten mg. Group B, eleven cases of pregnancy with renal symptoms (pre-eclamptic or kidneys of pregnancy). In this series the total non-protein nitrogen ranged from 29 to 52 mg. per 100 c.c. of whole blood and the ammonia urea fraction from 7 to 30 mg. Group C, 13 cases of eclampsia. In this group the total non-protein nitrogen varied from 25 to 72 mg. per 100 c.c. of whole blood, and the ammonia urea fraction varied from 11 to 50 mg. Group D, 4 cases, 1 of chorea, 1 with hemorrhagic retinitis, high blood pressure and headache, but with normal urine, and 2 cases of pernicious vomiting of pregnancy. In the latter two the total non-protein nitrogen and the ammonia urea fraction appeared practically normal and are for this reason worthy of note when compared to the derangement of the nitrogen seen in this condition. These investigators also estimated the elimination of phenolsulphonephthalein and found the results at variance with the rest of the clinical picture. They conclude that in pregnant women who have renal changes associated or not with toxic manifestations, there is usually a slight, and in most cases a definite increase in the total non-protein nitrogen, but the increase bears no relation to the severity of the symptoms. The amount of phenolsulphonephthalein eliminated varies so much with the clinical picture that the use of this test does not appear to be of much value either as a diagnostic or a prognostic aid in the toxemias of pregnancy.

THE PHYSIOLOGY AND PHARMACOLOGY OF THE EXCISED HUMAN UTERUS.

Lieb,³² whose work on the isolated uterus of guinea-pigs was reviewed in these columns a year ago, has further investigated the physiology and pharmacology of the human uterus and tubes, owing to the criticism that the guinea-pig uterus should not be compared with the human uterus. In reviewing the literature on the sub-

ject he mentions the work of Henricus, who first reported graphically the contractions of the non-pregnant human uterus. His tracings show three distinct types of waves: (1) small oscillations synchronous with the heart beat, (2) large excursions caused by the ascent and descent of the uterus during respiration, (3) large flat waves due to the contractions of the uterus itself. Later Kehrer has described three types of uterine contractions: (1) pendulous movements corresponding to those of the intestine, which he believes are present in the tubes and ligaments as well as in the body of the uterus, (2) tonus waves or variations in tonus, (3) contractions—(a) true peristalsis, (b) anti-peristalsis, (c) simultaneous and rhythmic contractions of the whole uterus, (d) strictures (a localized tetanus which occurs only at the tubo-uterine junction and at the internal os), (e) tetanus (a continuous contraction of the whole uterus). The last two types are pathological. All the movements described by Kehrer were powerful, sluggish, long-continued contractions alternating with strikingly long pauses.

Lieb, obtaining his material directly from the operating room, placed segments cut from them immediately into a large jar containing 500 c.c. of oxygenated Ringer's solution. If the specimen was to be studied immediately, the temperature of the solution was maintained at 38° C. If the tissues were to be reserved for later experiments they were kept at from 5 to 10° C. Lieb obtained well marked spontaneous contractions 105 hours after operation with tissues that had been kept in well oxygenated Ringer's solution and supplied with glucose. For the study of uterine tissue a small segment was excised from the gross specimen.

Uterine Movements. In the non-pregnant uterus the contractions of the external muscular coat were found to be slow but powerful, the contractions occurring at the rate of ten to sixty per hour. In the parturient uterus the movements of the external longitudinal coat are of two types. In the first they are simple waves. In the second type they are large coarse waves, on which are superimposed smaller contractions. The latter correspond to the waves of type one, while the coarser waves are probably manifestations of a change of tonus. The rate of the small contractions is subject to considerable variation, but is probably not far from 60-75 an hour.

Movements of the Fallopian Tubes. In the non-pregnant tubes the longitudinal fibres have a much faster rate of contraction than those of the body of the uterus, from 120-200 per hour. Occasionally there is an ill-defined tonus wave on which the smaller contractions are superimposed. In the circular fibres the movements resemble those of the outer layer. In the parturient tubes the movement of both the circular and longitudinal fibres became slower but much stronger. The tonus changes were very pronounced.

The Origin of the Uterine Movements. It seems clear to Lieb from the above experiments that the uterus and tubes contract and relax rhythmically when completely separated from the central nervous system. Furthermore, uterine movements are not secondary to impulses derived from the large nerve plexuses in the immediate neighborhood. Inasmuch as strips of muscle of the middle coat show spontaneous contraction, and inasmuch as the movements are not due to impulses derived from the central nervous system, nor from the adjoining nerve plexuses, they must originate within the organ itself. They may be due to an inherent rhythmic function of the muscle cells themselves, or they may be the result of impulses formed in the nerve cells, found in the walls of the tubes and uterus. The absence of a well defined nerve plexus corresponding to Auerbach's plexus in the wall of the intestine, leads Lieb to believe that the stimuli arise within the muscle fibres. From the fact that the tubes contract more rapidly than the body of the uterus itself, Lieb suggests the possibility that the contraction wave begins in the tube, sweeps over it, and finally involves the uterus proper.

PHARMACOLOGY OF THE HUMAN UTERUS.

Epinephrin. Elliot has shown that epinephrin stimulates the myoneural junctions of the true sympathetic system and that the response of any organ simulates in all respects electrical excitation of its sympathetic nerves. The response may be inhibitory or motor. Langley and Anderson have shown that the sympathetic nerve supply to the uterus of the rabbit is always motor. Whether the uterus is pregnant or not, stimulation of its sympathetic nerves invariably causes an increase in the activity of the organ. Epinephrin produces a similar effect. On the other hand, Cushney, Dale, and Kehrer discovered independently that the response of a cat's uterus varies with its functional condition. The non-pregnant organ is inhibited by sympathetic stimulation and by epinephrin. The pregnant uterus is thrown into increased activity. Gunn and Gunn have shown that sympathetic stimulation and epinephrin inhibit the uteri of rats and of guinea-pigs regardless of the physiological state of the organ. "The importance of the innovation of the human uterus now becomes apparent. Is the sympathetic nerve supply to the uterus motor or inhibitory? Is its influence modified during pregnancy? If it is inhibitory in character the employment of epinephrin during labor or in postpartum hemorrhage is dangerous, for it will lead to relaxation and inhibition of the uterus." Lieb found that epinephrin caused the non-pregnant isolated human uterus and the parturient tube both to contract powerfully and with a great increase in the rate of the movements. He concludes, therefore, that the sympathetic innervation of the human uterus is always motor in quality and that the beneficial effects of an

epinephrin douche during post-partum hemorrhage can now be explained. In addition to the constriction of the bleeding vessels, epinephrin produces a contraction of the uterus itself.

Lieb found that the effect of fluid extract of ergot on the isolated uterus and tubes has been, on the whole, disappointing. Only a slight increase in tonus occurred, but there was also a considerable augmentation of the rate and strength of the individual movements. He, furthermore experimented with the three active constituents of ergot, as shown by Barger and Dale. Of these, ergotoxine is an alkaloid specific to ergot. Ergotoxine caused the uterus to contract powerfully and pass into very high tonus. There was a suggestion of tetanus, soon broken through, however, by numerous contractions. The effect was extremely persistent, and despite repeated watching was still present at the end of 75 minutes. Lieb remarks that this marked stimulation of the isolated uterus is interesting in view of the fact that clinically ergotoxine has been shown not to influence the strength of labor pains. The reason is at once explained when the relative doses are considered. The amount causing such powerful contractions in the isolated uterus could not be safely administered to parturient women. Para-hydroxyphenylethylamine, one of the amines present in ergot, is closely related chemically to epinephrin. Its effect on a non-pregnant uterus was to cause a well defined tetanus. In the parturient uterus there was a marked increase in tonus, but neither the rate nor the strength of the contractions was much affected. Beta-imidoazolyethylamine, the third active constituent of ergot, caused an increase in tonus in the parturient uterus, and a distinct tendency towards tetanus.

Pituitary Extract. Pituitary extract produces a marked activity in a strip of muscle from a parturient uterus or tube. The stimulation is very persistent and not easily removed. In only one instance did pituitary cause even a transitory tetanus, and then only after a very large dose was given. On a parturient tube a marked increase in tonus was evident and the movements became less well defined. The effect of pituitary on the non-pregnant tube or uterus is surprising. Small doses usually have no effect. Large doses, such as produce marked stimulation of the pregnant uterus may cause very definite depression, or they may not influence the movements at all. Lieb remarks on the different effect that pituitary extract has on the pregnant and the non-pregnant uterus, and continues to say: "The simplest explanation would be that, like the cat's uterus, the human organ changes its innervation, or rather, during pregnancy its motor innervation becomes predominant. Such, however, is not the case, for epinephrin produces stimulation of the human uterus, whether it is pregnant or not. Nor does the parturient organ appear more sensitive to epinephrin. The only explanation which offers itself is that some substance sensitizes the uterus to pituitary. What

this substance is, whether it is maternal or fetal in origin, I do not know. The sensitizer is certainly not epinephrin. In two experiments the effect of pituitary was compared before and after treating the non-pregnant uterus with epinephrin. In one case the depression produced by pituitary was as marked after as before the epinephrin. In the other, pituitary was without effect before and after the epinephrin application."

Book Reviews.

Diagnostic and Therapeutic Technic. A Manual of Practical Procedures Employed in Diagnosis and Treatment. By ALBERT S. MORROW, M.D. Second edition. Octavo of 834 pages, with 860 illustrations. Philadelphia and London: W. B. Saunders Company. 1915.

The first edition of this descriptive manual was reviewed in the issue of the JOURNAL for Jan. 11, 1912 (Vol. clxvi, p. 59). In this second edition the original has been thoroughly revised and much new material added. There are forty-five new illustrations and some of the previous ones have been redrawn. The plan of the work, however, remains unchanged and it should continue a valuable reference guide for students and practitioners.

THE BOSTON Medical and Surgical Journal

An independently owned Journal of Medicine and Surgery, published weekly, under the direction of the Editors and an Advisory Committee, by the BOSTON MEDICAL AND SURGICAL JOURNAL SOCIETY, INC.

THURSDAY, APRIL 22, 1915.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States. \$6.56 per year for all foreign countries belonging to the Postal Union.

The editor will be in the editorial office daily, except Wednesday and Sunday, from twelve to one-thirty p. m.

Papers for publication and all other communications for the Editorial Department should be addressed to the Editor, 126 Massachusetts Ave., Boston. Notices and other material for the editorial pages must be received not later than noon on the Saturday preceding the date of publication. Orders for reprints must be returned in writing to the printer with the galley proof of papers. The Journal will furnish the first one hundred reprints for half the cost price.

All letters containing business communications, or referring to the publication, subscription, or advertising department of the Journal, should be addressed to

ERNEST GREGORY, *Manager.*

126 Massachusetts Ave., Corner Boylston St., Boston, Massachusetts.

BEDLAM AND ITS PHYSICIANS.

PERHAPS there is hardly a better example of odd words and their ways in English speech, than Bedlam, that ancient British institution which has become the prototype in literature, as in medicine, of the lunatic asylum, with all that it denotes and connotes. This institution, half alms house, half prison, first founded in 1247 as an adjunct to the monastery of St. Mary, Bethlehem, Palestine, derived its original name and character from those of the mother foundation. Later, becoming separated from this foundation, it has continued an independent existence to the present day and remains one of the most ancient and interesting organizations in medical history. Like all British institutions, Bethlehem Hospital has been constantly and intimately in contact with the life of its time, and its history is interwoven with that of medieval England and of many of the characters in every profession and class by whom that history has been made. Probably no hospital of equal importance has

had a history of more than six centuries so fully documented; and a debt of great significance is owed to the present chaplain of the hospital, the Rev. Edward Geoffrey O'Donoghue, who has recently gathered into a fascinating and fully illustrated volume* the data bearing upon the institution from its origin to the present day. The author's work is done with a charm of style that makes it not only interesting but delightful to read, and presents the story of Bethlehem Hospital with a vividness that is at once romantic and yet historically reliable and accurate. Moreover, the book shows most fully what has been the attitude of society throughout this period towards its insane poor, an attitude associated in the past with brutal abuses, which have been only gradually, and in some cases recently, remedied. From this sociologic aspect, then, as well as from a literary and historical standpoint, the book is of value and concern to modern readers of the medical and allied professions, as well as to the general public.

In the original charter, granted by Henry III, in 1247, protection without term was afforded to the brethren of the House of "Betleem," whose priory was founded in Bishopsgate without, that part of the highway leading through the Bishop's Gate and lying just beyond the walls of London. For nearly a century these brethren not only dwelt at their priory, but "roamed up and down England collecting alms and granting absolution." Finally, in 1329, Edward III granted protection to the Bishop's Gate Hospital or Hospice, apparently the same institution without the walls, where the charitable monks had become accustomed to shelter and care for insane and other mendicants and aged pensioners. Throughout these early days the name of the Hospice was variously spelled "Betlem" and "Bedlem," from which, in later times, was derived the word "bedlam," with which we are familiar.

Very early in its history we find Bedlam hospital associated with the names of the earliest figures in the medical profession of England. One of the first of these was John Arundell, one of the masters of the Bishop's Gate Hospital, a doctor of physie who, in 1457, performed for the institution the functions which we associate with a medical superintendent. Even before him it is probable that those two early pillars of

* The Story of Bethlehem Hospital from Its Foundation. By Edward Geoffrey O'Donoghue. New York: E. P. Dutton and Co. 1915.

English medicine and surgery, John of Gadesden and John of Arderne were, in some capacity, connected with the hospital, since both were presumably priests, and as such would be familiar visitors at the various ecclesiastic foundations of the city. All three of these early English leeches were also physicians to the king, so that the hospital, from its outset, was under fairly intimate royal protection and patronage, through the medium of these men.

Moreover, Bedlam was concerned not only with the court and with the medical profession, but came in contact also with men of letters. In 1408, when John Gower, friend of Chaucer and author of the "Confessio Amantis," lay dying in the cloister of St. Mary's priory at Southwark, he left a legacy of 8 pence to each of the poor patients in Bedlam. This gift seems pathetically prophetic of the similar, though more bountiful, bequest in a later century, of Dean Swift in Dublin, who

Left the little all he had
To found a home for fools and mad.

Bedlam is also referred to, in their works, though not in their wills, by various contemporary men of letters throughout the history of the institution. Evelyn records in his diary under date of April 21, 1657, that he "stept into Bedlame, where I saw several poore, miserable creatures in chaines." Ford in "Perkin Warbeck," makes Symnel say of Perkin,

He's past
Recovering; a Bedlam cannot cure him.

And so recently as our own time Dickens in "Bleak House," says through the mouth of Mr. Snagsby, "Why, not to put too fine a point on it, this is Bedlam, sir." The old English comedy, "Dickon of Bedlam," composed in 1557, deals largely with life in the hospital; and Thomas Dekker, that picturesque and profane Elizabethan, lays many scenes in one of his plays at Bedlam. Shakespeare himself refers to Bedlam repeatedly in King John, King Lear and several of the historical plays.

Sir Thomas More, reformer, seer, and author of "Utopia," lived in the sixteenth century, at Crosby Place, just opposite the Bedlam hospital in Bishopsgate. He must have had intimate personal knowledge and observation of the ways and manners, both of the patients and their attendants, at this institution, for in his "Four Last Things" he says whimsically, "Think not that everything is pleasant that men for mad-

ness laugh at, for thou shalt in Bedlam see one laughing for the knocking of his head against a post, and yet there is little pleasure therein."

Bedlam was not long, however, the only hospital for the insane in London. In 1553 Bridewell Hospital was incorporated by letters patent, and from that date continued a sister institution. In 1557 Bedlam and Bridewell were placed under the same administration, and the history of the two thereafter is most intimately interwoven. Apparently the affiliation was not altogether for the benefit of the two institutions and led to new abuses in the administration of both, especially under the mastership of Dr. Hilkeiah Croke, a Suffolk man, graduate of Cambridge and Leyden, who, in 1604, was appointed physician to James I. He wrote a book on anatomy, "Mikrokosmographia," and was regius professor of anatomy and lecturer on that subject at the college of barber surgeons. Dr. Croke was elected keeper of Bedlam on April 13, 1619, and served in that capacity until 1633. It was during this period that Middleton in his "Changeling," portrays the character of the keeper of the house, evidently sketched from this incumbent.

Early in Croke's mastership, there began to be complaints of his administration. In 1620 was issued an anonymous pamphlet entitled "The Petition of the Poor, Distracted People in Bedlem," in which complaint was made to the governors about the care of the inmates. The keeper, Dr. Croke, absorbed in his literary avocations and private practice, visited the hospital only on quarter days and refused to render any account of his financial responsibility. As a result, the treatment of patients by their irresponsible attendants went from bad to worse. Lupton, a contemporary writer during the mastership of Dr. Croke, says of Bedlam, "It seems strange that anyone should recover here; the cryings, screechings, roarings, howlings, shaking of chains, swearing, frettings, are so many and so hideous." Finally Croke's friend and protector, James I, died and Charles I, his son and successor, proved no such patron indulgent. The neglect and exactions of the hospital had become the cause of such scandal that investigation of both Bedlam and Bridewell was ordered and was carried out by two commissions, which reported respectively in 1632 and 1633. As a result, Dr. Croke was dismissed, in spite of his protests and appeals, though he escaped

prosecution for his pecuniary malfeasance, which evidently had been enormous. Out of donations of some £300, the institution had been managed on less than £60 a year, the balance having been pocketed by the keeper. In addition he had profited by various legacies and fees from the friends of patients. As a result of his disgrace, Dr. Crooke was called upon to resign his fellowship in the college of physicians. He led a random and pitiable existence for some ten years longer and probably died in 1643.

It is a relief to turn from this tale of maladministration and professional irresponsibility to the better days which followed almost immediately. In 1676 Bethlehem Hospital was removed from its medieval home, to a new and commodious building on the city moat at the edge of Moorfields. The total cost of this "New Bedlam" was £17,000, a sum which was raised partly by donations and partly by loans. It was the very next year that there was published a celebrated review entitled "Bedlam Broke Loose," which recorded the "boisterous uproar whereby the lives of the Right Honorable Digby, Lord Gerard, and his mother were eminently endangered" from an assault by an escaped patient. After the establishment in its new home, however, such occurrences became less frequent or unknown in the history of Bedlam. In 1683-4 there was appointed as visiting physician to the hospital, Dr. Edward Tyson, progenitor of a famous English medical family. He treated, instead of punishing, their physical and mental infirmities, established cleanliness and sympathetic discipline in the hospital life, and for the first time introduced really competent nurses instead of brutal attendants and jailers. As a result, not only was the opprobrium of the institution largely removed, but some of the patients actually began to be discharged cured in body and in mind. Dr. Tyson even instituted a system of after-care, to anticipate the likelihood of relapse. He made follow-up visits to discharged convalescents in their homes, provided them with clothing and necessities, and instructed them in habits of industry and right living. He also organized an outpatient or psychopathic department, where former patients might continue to receive treatment and where suspected cases might go for observation. In fact, Tyson resembled his odious predecessor Crooke only in that he was one of the foremost anatomists of his day and published elaborate monographs on the compara-

tive anatomy of the porpoise and the chimpanzee. Dr. Tyson died on August 1, 1708, and was honored by a public funeral procession in which marched the governors of the hospital, the apprentices of Bedlam and Bridewell, many physicians and merchants of the town, and former patients. He was buried in Allhallows Church on Lombard Street, and there his monument still records that "He was to the last hour of his life the devoted physician of Bethlehem Hospital." In his will he left a large legacy for the benefit of the hospital and of other charities in which he had been interested.

Of the later days of Bedlam, Hogarth has perhaps left us a more vivid picture than any which could be made in words, but if abuses recurred under administrations succeeding that of Tyson, they were remedied again by the work of other successors, such as Dr. Richard Hale, the two Drs. John Monro, Dr. James Monro, and others. Finally, in the nineteenth century, the hospital was again removed to its third and present home in St. George's Fields, where the building constructed in 1815, and since several times remodeled, still houses the institution.

There have been many other honorable and notable physicians who have served during this past century and are still serving in the administration of Bedlam, but the change which has been effected, the contrast which prevails between their institution of today and that of the middle ages affords encouraging illustration and realization of the genuine progress of humanity, science and civilization in the five hundred years of the history of Bedlam.

IMPORTANCE OF RESEARCH IN LEPROSY. SIGNIFICANCE OF PULSE RATE IN THE DISEASE.

IN another column of this issue of the JOURNAL we publish the first instalment of a continued article by Dr. Honeij of this city, presenting an important study of leprosy, with especial reference to the significance of pulse and temperature during that disease. This study represents a continuation of the work upon which a preliminary report was made in the issue of the JOURNAL for February 12, 1914 (Vol. clxx. p. 233). In this report Dr. Honeij first suggested the possibility of the value of fluctuations

in the pulse as an indicator of the progress of the disease, and expressed the belief that the observed reversal of the usual febrile diurnal pulse curve might prove of real prognostic importance. As a result of his further investigation, as represented in the present article, Dr. Honeij has demonstrated that "there occurs a definite clinical temperature and pulse curve diagnostic and prognostic of leprosy," with a "frequent and persistent high morning pulse rate in all cases." This constant high pulse rate is most marked in progressive and advanced cases, and "there is a correlation of temperature and pulse in early cases in contrast to a gradual increased pulse rate without similar reactions in progressive and advanced cases."

This valuable piece of medical research is, perhaps, the most important that has yet proceeded from the leper colony at Penikese Island, a hospital which affords a clinic capable of contributing material for useful research and contributions to the scientific knowledge of leprosy. Apart from their service to the individual inmates, the value of such institutions depends on the effective use which is made of them for the advancement of medical science, and in the case of the Penikese Colony the opportunity afforded for such use is considerable. From its alliance with the Harvard Medical School this opportunity is increased in the hands of the medical director, and, from the evidence of the present article, has already been effectively improved.

The importance of new diagnostic, prognostic and therapeutic discoveries with reference to leprosy is augmented by the gradual increase of the disease in this country, though perhaps this apparent growth may be chiefly due to increasing accuracy of detection and diagnosis. In Hawaii, where the disease is most prevalent, a law has been in force since 1909, making the apprehension and detention of lepers compulsory, and requiring all persons to report suspected cases to the Board of Health. In a recent bulletin (No. 66) of the United States Public Health Service, Dr. George W. McCoy presents the data of leprosy in Hawaii during the past thirteen years:—

"The total number of lepers officially apprehended since 1901 has amounted to 1060, or an annual average of about 82. Of this total, 52 were Portuguese, 14 belonged to other European nationalities, 13 were Americans, 29 Japanese, and 61 Chinese. About half of those apprehended were between the ages of 11 and 25 years. It is a curious fact that the incidence of

the disease is almost twice as high among males as among females, the respective figures being 673 and 387. Inquiry into the previous history of the cases showed that association with leprosy persons was admitted in nearly 37%, and in this number the presence of the malady in a parent, brother, or sister, constituted over half of the admitted association. In 188 cases the leprosy was alleged to have existed less than a year, in 131 for a whole year, in 99 for two years, in 92 for three years, in 48 for four years, and in 42 for five years. In 86 it had existed from six to 10 years, and in 49 for more than 10 years."

In the total of 1060 cases the bacillus leprae was demonstrated in 929. The nodular form of the disease now constitutes a larger proportion of the whole than in the past, there being 384 cases of this type, 327 of the anesthetic type and 275 mixed cases. During the two-year period beginning July 1, 1913, the cost of the leper colony at Molokai, Hawaii, was \$412,130.

These data indicate the importance and cost of the continued study of leprosy. There is every reason why the Massachusetts leper colony at Penikese should prove as valuable as that at Molokai, not only for the relief of the disease, but for its study and for contributions to its ultimate knowledge.

GOLF BALL ACCIDENTS.

A FORM of accident which is deplorable, not only on account of its serious character, but also because it is preventable, is the bursting of a golf ball, with its frequent result of destruction of eyesight. Accounts appear in the lay press from time to time of these mishaps, and these have been confirmed by several reports of such cases in medical journals. In a recent issue of the *British Medical Journal*, Drs. Elliot and Inman report such a case and refer to several others in the literature.

It appears that there is no danger of a golf ball exploding when subjected only to the ordinary vicissitudes of play, but the exploration of its interior by too curious individuals is apt to have a tragic denouement. Even then there would be no danger if the investigator would be content with unwrapping the ball layer by layer, but in many cases this process is too tedious and must be expedited by the use of a knife. The English authors mentioned above intimate that

* Abstracted in a recent issue of the *Lancet*.

s accident is less frequent in the British Isles than in America, because of the more inquiring turn of the Yankee mind.

Golf balls are dangerous only when the core is fluid, hence the air or the solid core balls may be cut into with impunity. The usual substance used in the liquid core is soft soap, which, of course, is strongly alkaline, and in some cases even more dangerous materials, such as sulphuric acid, have been found. Rarely, water is used and this is comparatively innocuous. The fluid is confined in a rubber bag tied with a string, and around this are wound many yards of rubber tape by machine, and the liquid is thus subjected to enormous pressure. When a knife is used to cut through these layers of tape it suddenly penetrates into the bag, and the liquid contents are ejected with great violence. Should any of these strike the eye, as has been the case a number of instances, the trauma itself plus the irritating character of the fluid, is likely to have serious results. Some cases have been seen by an ophthalmologist within two hours after the injury, and have been placed under a general anesthetic to permit of heroic treatment, but have, nevertheless, resulted in complete loss of vision.

There has been some legislative agitation to prevent the sale of liquid core golf balls, but only one state has actually passed such a law. Most golf clubs post warnings in their club houses against the cutting open of balls, but, unfortunately, this risky experiment is usually performed by caddies and others who do not heed these placards. One remedy, then, which should suggest itself would be that golf players refrain from presenting caddies with used balls, or at least warn them of the danger of cutting into them. Should a golf player wish to cut into a ball for any purpose he should not do it in the presence of bystanders; he should wear gloves, and he should place between himself and the ball he is dissecting some such protection as a pane of window glass.

Obviously it behooves the profession to warn their golf-playing patients of the dangers of the liquid core ball. If a case is seen immediately after a projection into the eye of the contents of a ball, thorough cleansing of the eye is, of course, imperative, even if a general anesthetic is required. Experts now state that the liquid core ball has no greater elasticity than the solid core ball manufactured by certain leading deal-

ers, therefore there would seem to be no excuse for this deadly plaything.

DR. WILLIAM WALLACE MORLAND, AN EARLY EDITOR OF THE JOURNAL.

A CORRESPONDENT has recently sent to the JOURNAL a clipping of a verse written by Dr. William Wallace Morland, a much beloved friend of his father, and a former editor of this JOURNAL. The verse is printed below. Dr. Morland edited the JOURNAL between the years 1855 and 1860. He, with Dr. Francis Minot, succeeded Dr. J. V. C. Smith, who resigned his long editorship to become mayor of Boston. In the issue of the JOURNAL for February 15, 1855 (Vol. lii, No. 2), the new editors published an editorial which they entitled "Our Difficulties, Our Resources, and Our Intentions," of which the following are excerpts:—

"It is far more difficult to conduct a weekly journal, so that it will prove acceptable and useful, than it is to prepare the more imposing quarterly, or even the monthly. We must avoid bulk and abstruseness of matter, at least generally. Articles which contain much that is valuable, in a condensed form, are indisputably those which should predominate. On the other hand, brevity must not render communications obscure, nor lead us to furnish a collection of mere *items* to our readers.

"We are well aware that the practitioner in the country, the greater proportion of whose time is taken up by his out-of-door duties, cannot if he would, read long and recondite articles; he needs a digest of medical novelties, and these should be selected with a view to their practical utility and truthfulness, or he will be better without them. The journalist should seek to give whatever will assist, be it only in those minor points which become questions in the daily round of professional duties. It is not, however, judicious to make a medical journal wear, too literally, the garb of the newspaper. While it is not easy to have it unfailingly light and sparkling, we believe it may at least, be always instructive."

That the task of editing a weekly journal in this practical and efficient manner did not prove to be a simple task, may be judged from the editorial written by Dr. Morland and Dr. Minot at the time of their withdrawal from the joint editorship in 1860, printed in the JOURNAL of January 26 (Vol. lxi, No. 26). They write as follows:—

"The dissolution of our official relations to the Journal, and through it to the medical public, is not, as will be imagined, a matter of indifference with us. Maintained, as they have been, for the period above mentioned, we can truly say that, although they have necessitated the expenditure of a very large amount of time and labor, they have in many respects proved highly advantageous to ourselves. The training which an editor of a medical periodical is obliged to undergo in the faithful discharge of his duties can hardly be other than wholesome discipline, even if fatiguing, and not infrequently irksome and exacting."

That Dr. Morland stood high in the esteem of his contemporaries is evident by the following paragraph from a record of the Boston Society for Medical Improvement.

"About the year 1840 interest began to wane: new blood was needed. Of this it received the best: Samuel Cabot, Jr., Henry J. Bigelow, George Hayward and Morrill Wyman; while S. L. Abbott, B. F. Cotting, N. B. Shurtleff, Buckminster Brown, Lyman, Morland, Oliver, Townsend, Gay, Derby and Francis Minot were among those admitted to the Society during the 1840-50 decade."*

It is also interesting to note that the record previously states that the "new-born 'Boston Medical and Surgical Journal' received the Society's support," and that in January, 1855, the publication of the transactions were transferred from the *American Journal of Medical Sciences* to the BOSTON MEDICAL AND SURGICAL JOURNAL, where they continued to appear until recent years.

Dr. Morland was the author of a book on "Diseases of the Urinary Organs," which met with considerable success. In 1866 he won the Fiske prize by an essay on uremia. His paper on "Florida and South Carolina as Health Resorts," which appeared in the JOURNAL in 1872, was the best and best known of his smaller writings. He died in 1876, sincerely mourned by his friends and confreres. His obituary in the JOURNAL states that "as a man and a physician Dr. Morland was alike excellent, of much learning and ability joined to the most charming and unpretentious manners."

The following Spenserian stanza, of his composition, shows that his "clerkly hand" had abilities in metrical as well as editorial composition.

HOME.

"Home is the altar where affection's flame
Unalterably bright should ever glow.
In lasting letters friendship's sacred name
Should beam upon the group that kneels below.
There if affliction's saddening power they know
Fond love should heal the wound with tender care,
Bend o'er the couch, and all things else forego
So that it soothe the heart and kindly share
The griefs which erring man is aye constrained to
bear."

LEGALIZATION OF ABORTION IN FRANCE.

A PECULIAR situation has sprung up in France in the wake of the German invaders. The claim is made that a number of French women are pregnant as a result of violation by the enemy. Naturally the situation is odious to them and numbers of them have appealed to the medical profession for relief. They protest against being obliged to carry to maturity the fruit of a forced union, especially since the assailants were enemies of their country. Consequently appeals for abortions have been made by many of these unfortunate women.

The question raised has naturally received a great deal of discussion. Many eminent physicians, whose patriotism and sympathy seem in times like these to be rather ascendent over their calm professional judgment, have expressed themselves as being in favor of this procedure. However, the balance of opinion seems to be against it, and the opinion expressed by Professor Landouzy of the University of Paris is the one which is generally accepted. He holds that the induction of abortion is justified only when the life of mother or child is jeopardized by the continuation of pregnancy.

To avoid the hardships which would eventuate if the families thus saddled with an unwelcome addition were obliged to support the child, M. Maloy has suggested a solution of this problem which has been adopted. The mothers are allowed to abandon these children to the State, which will bring them up as foundlings. The father is allowed to disclaim his paternity. It would be interesting psychologically to know whether or not in all cases the mother will be willing to surrender the infant, in spite of its alien blood.

* Harrington's History of the Harvard Medical School, Vol. II, p. 790.

MEDICAL NOTES.

BUBONIC PLAGUE AT HAVANA.—On April 10 there were reported to the Public Health Service two cases of bubonic plague and one death. The official bacteriologist of the Cuban government has been placed in charge of the situation.

TYPHUS IN SERBIA.—It is reported through the British Red Cross Commission to Serbia that typhus is increasing and the percentage of deaths is between 50 and 60%. At Monastir, for example, there were found three thousand typhus patients with only ten doctors to attend them. Report from Nish on April 11, states that thirty British and eighty French physicians have been sent from that city to combat the epidemic.

SMALLPOX AT SAN DIEGO, CALIF.—A passenger on board the steamer *Northern Pacific*, on its arrival at San Diego, Calif., was found to have smallpox and the steamer was quarantined. There were 327 passengers on board; all were vaccinated and a few allowed to land.

ERADICATION OF RATS IN NEW ORLEANS.—Since the campaign against plague was begun in New Orleans last autumn, 318,000 rats have been killed and subjected to bacteriological examination. Not a case of plague has occurred in the city since October 4, and Dr. W. C. Rucker, who has charge of plague eradication in the city, states that "it will not be long before New Orleans will be one of the most rat-proof cities in the world."

FIRE AT CHICAGO STATE HOSPITAL.—Report from Chicago states that on April 13 a wooden frame annex of the Chicago State Hospital for the Insane at Dunning, Ill., was destroyed by fire. Two hundred convalescent inmates were safely removed. The loss is estimated at \$50,000.

A FOUNDATION FOR THE STUDY OF COMPARATIVE BACTERIOLOGY.—It is announced that the Rockefeller Foundation has been empowered to establish an institution for animal research on property adjacent to Princeton University. Though not connected with the University, there will be a profitable coöperation between its laboratories and that of the foundation. Dr. Theodor Smith, now of Harvard Medical School, will be in charge of the scientific work, and with corps of assistants will be in a position to establish a laboratory which may become one of the greatest in the world for the study of comparative pathology. Over a million dollars is available for the erection of laboratories and their equipment.

ST. MARY'S HOSPITAL, ROCHESTER, MINN.—The twenty-fifth annual report of St. Mary's Hospital, Rochester, Minn., contains a record of 390 patients operated upon during the year.

and a total number of operations of 10,939. The capacity of the hospital for patients is three hundred beds. The report follows with a detailed list of operations performed. There were 893 operations for appendicitis, 1730 for goitre and 503 for gall-stones.

NATIONAL EFFORT TO IMPROVE TEACHING ON TUBERCULOSIS.—For the purpose of securing more co-operation from physicians and nurses in the anti-tuberculosis campaign, The National Association for the Study and Prevention of Tuberculosis has inaugurated a movement to bring the importance of this subject to the attention of these two groups.

Among the first things which the Association is trying to do is to induce the medical colleges and schools of nursing to give more instruction, particularly of a clinical nature, on tuberculosis. An effort will be made also to reach the individual practitioners and nurses by special booklets prepared for this purpose. The clinical and other facilities of the various organizations affiliated with the National Association will so far as possible be made available for the widest possible use in training doctors and nurses in tuberculosis work.

The object of this campaign is stated as primarily to secure more accurate and earlier diagnosis of tuberculosis on the part of physicians and to show nurses the great opportunities of service in the home care of consumptives.

NEW YORK DEATH RATE LOWER THAN LAST YEAR DESPITE THE GRIP.—The increase in the mortality as noted for the week ending April 3, 1915, continued during the past week and rose to even a greater height. The number of deaths during the past week was 1934, an increase of 103 deaths over the preceding week. Both weeks of April combined showed an increased mortality of 550 deaths over the corresponding two weeks of 1914. This unexpected rise in the death rate has had as its principal factor the increased prevalence of a virulent form of influenza. The number of deaths during the past week from this cause was 47, more than two and a half times as many deaths than were charged to this disease in the corresponding week in 1914. The effect as usual of the greater prevalence of influenza was not only an increase in the deaths from the diseases of the respiratory organs which influenza particularly affects, but also a greater increased mortality in many of the chronic organic diseases.

The deaths from acute bronchitis, broncho pneumonia and lobar pneumonia showed an increase of 173, chronic organic heart diseases, one of 49 deaths, chronic diseases of the kidneys, 37 deaths, diseases of the nervous system, 16 deaths, diseases of the digestive system, 35 deaths, and all forms of tuberculosis, 16 deaths over the figures for the corresponding week last year.

All ages, with the exception of children between one and five years of age, suffered from

this increased mortality. The infants under one year of age showed an increase in the number of deaths of 67, between 5 and 55 years of age an increase of 178 deaths, and at 65 years of age and over there were 119 more persons died than in the corresponding week of 1914. By reason of the diminished prevalence of scarlet fever and diphtheria the mortality of the children at the ages between one and five years was lower by 16 deaths; the death rate from all causes increased 2.41.

Despite the unfavorable influence of grip on the mortality, the health of the city this year compares very well with that of last year. The death rate for the first fifteen weeks of 1915 was 14.57 per one thousand of the population as against the rate of 15.52 in the corresponding period of 1914, a decrease of .95 of a point.

OFFER OF THE ROCKEFELLER FOUNDATION TO DR. GORGAS.—On April 11, Mr. Jerome D. Green, secretary of the Rockefeller Foundation, published the following official statement of the circumstances of an offer recently made by the foundation, to Major General William C. Gorgas, surgeon general of the United States Army.

"The Rockefeller Foundation has invited Gen. Gorgas to become a permanent member of its staff in the capacity of general adviser in matters relating to public sanitation and the control of epidemics. The trustees of the Foundation have for some time been aware of Gen. Gorgas's strong belief in the feasibility of completely eradicating yellow fever from the face of the earth. During these two years of the Foundation's existence the attention of the trustees has been carefully given to problems of public health, including the control of epidemics, and the need of a competent adviser and executive in this field has been strongly felt.

"When in coöperation with the American Red Cross, the Foundation undertook the important task of helping the Serbian government to control the epidemic of typhus and the threatened epidemic of cholera, the trustees again naturally thought of Gen. Gorgas as a man pre-eminently fit to be of service in this emergency, and at a meeting held in New York last week they decided to make him a definite offer. This offer is now taken under consideration, and he will doubtless communicate his decision within a few days. The Foundation's invitation contemplates his retiring from active service, as he is now entitled to at any time, but it does not contemplate his resignation from the army unless he should be assigned to duties of such nature as to be incompatible with the regulations affecting retired officers.

"Such a duty would be involved in his going to Serbia at the present time, which he could do as a representative of the Rockefeller Foundation, but not as an officer on the retired list of the army. The sanitary commission of the American Red Cross has actually been sent to

Serbia in charge of Dr. Richard P. Strong of the Harvard Medical School, as director. The Rockefeller Foundation is co-operating with the American Red Cross in the support of this expedition, and if Gen. Gorgas should except the Foundation's offer he will doubtless be largely influential in determining the nature and extent of its participation in the work.

"In justice to Gen. Gorgas it should be stated that there is no foundation whatever for the statement that he is to receive a salary of \$50,000. The offer of the Rockefeller Foundation includes a moderate salary and the assurance of the usual allowances in the event of resignation or death. If the offer proves attractive to Gen. Gorgas it will be because of his sympathy with the general aims of the Foundation in regard to public health and his belief that the resources placed at his disposal will enable him to render a large service to humanity along the lines of his professional experience and ambition."

It is not yet definitely announced whether Dr. Gorgas will accept this offer, but it is sincerely to be hoped that he may be able to do so since his services, important though they are, to the army, can thus be more effectively employed in a wider field for the benefit of a greater number.

EUROPEAN WAR RELIEF FUNDS.—On April 17 the totals of the principal American relief funds for the European War reached the following amounts:

	N. Y.	N. E.
Belgian Fund	\$1,019,089.92	\$248,179.57
Jewish Fund	615,770.43	
Red Cross Fund	479,615.18	
American Ambulance	385,562.89	
Committee of Mercy	142,441.20	
Polish Fund	38,062.71	43,630.85
Serbian Fund	27,050.00	
Persian Fund	24,542.11	

BOSTON AND NEW ENGLAND.

BOSTON CITY HOSPITAL ALUMNI ASSOCIATION.—The annual meeting of the Boston City Hospital Alumni Association, held in this city on April 7, was attended by seventy-five members and their guests. Dr. Paul Thorndike was toast-master at the dinner and the principal speakers were Dr. John B. Blake, Dr. Homer Gage, Dr. John J. Dowling and Dr. Robert W. Lovett. Dr. Lovett was elected president for the ensuing year. Dr. Henry A. Wood, vice-president, Dr. Cadis Phipps, secretary, Dr. William R. P. Emerson treasurer and Dr. Edward H. Nichols a member of the executive committee for five years.

BOSTON MILK AND BABY HYGIENE ASSOCIATION.—The recently published sixth annual report of the Boston Milk and Baby Hygiene Association records the work of that organization for the past year. During this period 4,097

babies were cared for by the Association which now maintains twelve milk stations in various parts of the city. In 1911 the infant mortality in Boston was seventh among the large cities of this country; in 1912 it was fourth, in 1913 third and 1914 second, being tied with St. Louis at a rate of 103 per thousand births.

FOOT AND MOUTH DISEASE IN MASSACHUSETTS.—There have been reported no new cases of foot and mouth disease in Massachusetts since March 18. While it is reasonable to hope that the disease has finally disappeared, the Bureau of Animal Industry is still maintaining a strict quarantine, for it is possible for the germs of the disease to require this length of time for their incubation. A like number of days occurred between the first and second outbreaks and the department is not willing to relax its vigilance until all possibility of infection is past.

MEDICAL LEGISLATION.—On April 13 Governor Walsh signed a bill, recently passed by the Massachusetts General Court, intended to prevent communication of dangerous diseases in mattresses and other articles of bedding. It is provided by the bill that it shall be a criminal offense "to manufacture or sell any mattress, pillow, cushion, or similar articles which contain any material previously used in or about a hospital or in connection with any person who has suffered from an infectious or contagious disease." The penalties provided for violation of the provisions of this law are imprisonment for six months or a fine not exceeding \$500.

A NEW BUILDING FOR SHARON SANATORIUM.—In its recently issued annual report, Sharon sanatorium announces the receipt of a gift of sufficient funds to erect a new building for the treatment of children suffering from tuberculosis. It is to be built as a memorial of a friend of the sanatorium whose relatives have made the gift for this purpose.

CONFERENCE ON HEALTH BOARD ADMINISTRATION.—On April 29 there will be held in Ford Hall, Boston, a conference under the joint auspices of the State Department of Health and the Massachusetts Association of Boards of Health, to discuss the general subject of cooperation between the local boards of health and the State department. Every city and town in Massachusetts is asked to send representatives. The speakers for the morning session will include President Emeritus Charles W. Eliot of Harvard, Professor Irving Fisher of Yale, Miss Adelaide Nutting of Columbia, Governor Walsh and Health Commissioner Dr. Allan J. McLaughlin. In the afternoon the heads of some of the divisions of the State Department of Health, district health officers and representatives of the municipalities will speak, followed by a general discussion.

NEW BIOLOGICAL LABORATORY AT BROWN UNIVERSITY.—The Arnold Biological laboratory, presented to Brown University by Dr. Oliver H. Arnold of Providence, has just been opened to classes. The building will accommodate 400 students including graduates. Dr. Arnold's legacy of \$80,000 represented the savings of a lifetime of a physician with a country practice.

HOSPITAL BEQUESTS.—The will of the late Mary B. Lewis of Framingham, Mass which was filed on April 6 in the East Cambridge Probate Court, contains a bequest of \$2000 to the Framingham Hospital.

The will of the late Anna E. Smith, formerly of Boston, who died recently in New York City, was filed for probate on April 7. It contains bequests of \$200,000 to the Peabody, (Mass.) Home for Aged and Indigent Women, \$7,500 each to St. Luke's Hospital, New York, and the Inwood Home for Consumptives; and \$5,000 each to the Mary Hitchcock Memorial Hospital, Hanover, N. H. and the Massachusetts Homeopathic Hospital, Boston.

The will of the late Catherine Brown of Malden, Mass., which was filed on April 13 at the East Cambridge Registry, contains a bequest of \$2,500 to the Malden Hospital.

Massachusetts Medical Society

HAMPSHIRE DISTRICT MEDICAL SOCIETY.—The annual meeting of the Hampshire District Medical Society will be held at the Forbes Library, Northampton, Thursday, May 13, 1915, at 11.30 o'clock, a.m. Officers of the Society and councillors, censors and a commissioner of trials for the general society will be elected and the presidential address will be given by Dr. Edward W. Brown, of Northampton.

JOSEPH D. COLLINS, M.D., *Secretary.*

Miscellany.

THE GERMAN BIRTHRATE.

IN previous issues of the JOURNAL we have, from time to time, commented on the steadily declining French and English birth rates. This decline has made itself felt also, though to a less extent, in recent years, in Germany. In the issue of the *Lancet* for March 20, is a report of a paper on this subject presented at a meeting of the Deutscher Verein für Oeffentliche Gesundheitspflege, by Dr. von Gruber, from which the following extracts seem of interest.

"In the year 1870 per 10,000 inhabitants the total of marriages was 77, of births 401, and of deaths 290. In 1911, the latest year for which complete statistics are available, the total num-

ber of marriages was 78, that of births 295, and that of deaths 182. Thus, in spite of the declining birth rate, the excess of births over deaths has remained almost constant.

"This shows that though the number of marriages has practically not changed, the birth rate has fallen by more than 25%, and the mortality by 35 to 40%, which fact accounts for the increase in the nation's surplus population. The fall in birth rate is, curiously enough, greatest in the hitherto so prolific Saxony, where it is more than 40%. The fall is greatest in the towns and centres of industry, but it is also evident in the country districts, particularly in the neighborhood of large towns. As a rule, the fall is greater and more rapid among Protestants than among Catholics, and it is greatest in communities which elect Social Democratic representatives. The fall is most striking in Berlin, where the birth rate has diminished by a third within the last thirty years. Here the birth rate is highest in the working-class districts, but even in these the fall is noticeable. It is beyond dispute that the lower classes in town and country have followed the example of the upper classes in the limitation of offspring. Berlin can no longer maintain its numbers by its own birth rate; thus in 1912 1000 women, whose ages ranged from 15 to 45 years, gave birth to only 73 living children, and this figure would have to be raised to 113 if the population of Berlin were to be kept up to its present level.

"The fall in the birth-rate is largely due to alcoholism and venereal disease, both of which are on the increase. Venereal disease, in particular, is to blame. In 1910 it was estimated that in a very large sick-club in Berlin 4.9% of the women and nearly 9% of the men suffered from venereal disease. Lenz has even calculated that 90% of the men in Berlin have at some time been infected with syphilis. What, however, is most important is the dependence of the decline of the birth rate on systematic prevention of conception. A table dealing with the fall of the birth rate in Berlin shows that this fall applies particularly to the birth of children in families already possessing a child or two. Once Germany adopts the two-child system the methodical temperament of the nation will ensure its uniform practice and inevitable consequences. Particularly ominous is the low productivity of the most gifted. Cross breeding among the mentally well endowed is of great importance in the evolution of intellectual qualities, as is well illustrated by the Imperial House of Hohenzollern. Nothing is more important for the existence and welfare of a nation than a sufficient supply of gifted leaders; without such the mass of the people is helpless.

"The causes leading to the voluntary limitation of the family are many. Recent advances in science, improving the conditions of life and prolonging it, are all to the good of the individual rather than of the community. Indeed, these interests are apt to clash, and owing to the

present selfish individualism of man, a course is often chosen which benefits the present generation at the cost of succeeding generations. The family is no longer an institution for the reproduction of the race; and the child's work and support of the family are progressively reduced by laws insisting on hygienic and educational measures and the limitation of child labor. Owing to insurance against old age and disease, parents no longer feel the necessity for creating an offspring which shall keep them in their old age. Lack of house accommodation in the towns, the employment of the mother outside her home, and the employment of girls in shops and factories instead of in domestic duties, render the successful rearing of large families difficult."

By way of remedy for these conditions the following suggestions are made:—

"An estimate of the fate awaiting a nation which methodically adopts the two-child system shows that a population of a million with a yearly birth rate of 19.8 to the thousand must after 15 years have dwindled to 918,400, after 50 years to 676,938, and after 100 years to 347,075. Ultimately the wealth of the individual would suffer. At present, according to Prussian statistics, the income per head of the population is 260 marks. According to the above hypothetical calculation of the decline of the population, the income per head would have risen after 15 years to 283 marks, but after 50 years it would have fallen to 269, and after 100 years to 265 marks. It is not sufficient to rely on reducing the infant mortality, for even if this were brought as low as 7%, to which figure only New Zealand and Norway have attained, the gain thus effected would be practically neutralized by a further fall in the birth rate of 2 per 1000.

"It is, therefore, imperative that a reform should aim at encouraging fertility and removing the advantages at present associated with sterility. The substitution of polygamy for monogamy, the emancipation of woman, and the state supervision of the child are inferior to the old family system economically and from the point of view of race-hygiene and culture. The maintenance and education of children in public institutions would be twice as expensive as the present family system. Were the family tie dissolved and loose connections substituted, venereal diseases would spread, the standard of parentage would be lowered, and the frequency of sterility would be increased. It is an insufficient inducement to give birth to a child that its mother is permitted to visit it every Sunday in some state institution. The family ties must, therefore, be strengthened, and the attempt to place the married and unmarried mother on an equal footing must be checked. The present popular vogue of honoring the unmarried mother has little to do with compassion for her fate or a misplaced fervor for the preservation of the race; it is rather an insidious attempt to raise the social status of the unmarried

mother and thus sweep away a hindrance to loose connections.

"For the sake of large families housing accommodation should be improved, garden cities should be built, and cultivation of the land should be encouraged. The community as a whole should contribute so largely to the rearing of children that it would be practically as cheap to have a large as a small family. These contributions should be available for every class, from the lower to the upper middle; for it is deplorable that the most virile class, to which officers belong, should find it difficult to raise large families. The standard of fertility should be so high that each couple would breed 3.75 children, which, after the necessary reductions, would be equivalent to about three children living to the age of 14 years. Were the Government to subsidize with 200 marks a year every child in excess of the first two, Germany, with a population of 66.3 millions, would have to pay 840 million marks a year. This sum could be raised by progressive taxation of the unmarried, of the childless, and of families with few children. Taxes on luxuries could also be raised for this purpose. It must be admitted, however, that an evil such as the two-child system cannot be eradicated by legislation."

It is evident that the apparently inevitable effect of high civilization in reducing the birth rate has already been making itself felt in Germany, though thus far to a less extent than in France, the United States and England. It remains to be seen whether German methods of efficiency, by the recognition of this disastrous tendency, will be able to control and correct it before its results become fatal to the nation. The decision of this question is, perhaps, one of the most interesting of the many involved in the outcome of the present European war.

Correspondence

PARIS LETTER.

FRENCH COSTUME IN WARTIME.

(From Our Special Correspondent.)

PARIS, April 3, 1915.

Mr. Editor: When I was a student at the Faculty of Medicine here Professor Tarnier was a man already well on in years; he used to spend a good part of his lecture-hour in re-adjusting an impossible pince-nez that slipped from his nose at every gesture, and in stumbling over the pronunciation of the word dyspnea, at which his tongue balked with an invariability truly remarkable. The Professor is usually supposed to have invented the axis-traction forceps; but popular report as to this point ran somewhat otherwise. The Tarniers were two,—one the obstetrician, the other an artillery colonel; now it was creditably advanced that the obstetrician put in all his time on cannon, but that the afore-mentioned forceps was really the fruit of the gun-man's brain! This species of mental aberration, the succumbing to

the fascination of something altogether out of one's real province, is a phenomenon by no means rare; and it is an attack of something on the same order that leads me, I suppose, to wish today to hold forth on a topic for which I am eminently unfitted,—that of clothes.

Walking along the Avenue du Bois this Sunday afternoon, it was impossible not to be struck by the extreme sobriety of the women's dress; a great many were in full mourning, of course, and it seemed as though the rest had discarded every attempt at fashion or color out of respect for the feelings of their sorrowing sisters. It was all in the proper note, and very much what was to have been expected from this warm-hearted people; but still, I have never been impressed so forcibly by the sight before,—possibly because it has been a long time since I have been in the midst of such a crowd as there was out walking today. According to the Almanac it was Palm Sunday; but from the atmospheric conditions one would never have dreamed that we are so far on in the year, or that April will be here in half a week; the horse-chestnut buds are not yet opening along the Boulevards,—the season being in fact practically three weeks late.

For several months I have been making the remark to myself that never before have I seen so many comely young women moving about, and particularly of one class,—possibly what might be called the lower-middle, the wives of the better-paid workmen, the class of woman that in Paris wears no hat, but goes about neatly-dressed and bare-headed. At the present moment you see these respectable, attractive women, with or without a child or two, all over the place; and the reason for this unusual occurrence is, I imagine, the following: Under normal conditions the women of this category stay at home and look after their ménage, only moving abroad with their menkind on Sunday afternoons or Fêtes; but their husbands are now all away at the war, and they have, therefore, to hustle about themselves, on errands, to draw their allowances, and for a multitude of reasons depending on the war, not the least weighty of which is the expediting of the frequent packages of cigarets and chocolate to the *bonhomme au front*. Never at any time during my long sojourn in Paris have I seen so many good-looking Frenchwomen, no, not even during the month of June, in Grand Prix week of a normal year; you can then see plenty of fine clothes, but not many pretty faces, except now and then among the ranks of the *haute cocotterie*. Again and again I have lost myself in admiration of the garb these women adopt. Having little money, only enough to keep the home going, they make no attempt at dress; with a neat and becoming coiffure, a plain black coat covering everything, they present a contrast to the slatternly London and New York women of the same class that is as striking as it is unflattering to the latter.

Paris is for the moment simply swarming with soldiers. What they can all be doing here, God only knows! They are not wounded; on the contrary, fine strapping fellows, with a color on their faces that seems to indicate actual service. If General Joffre has so many men that he can afford to let them spill over loose in this way, why so much the better for our side. But we are talking about clothes today, and what I wished to say in this connection bears on the new French uniform. I ought rather to put the word in a multi-plural, for no two of these *poilus* seem to have the same; if this state of affairs continues it will be a mighty wise colonel who will know his own *terribles-toriaux*,—or, excuse me,—*regulars*, as there are no more territoriaux now, they having all been promoted to regulars for good conduct, so that one sees regimental numbers running up into the *four-hundreds*! I ought to explain that it was long ago decided that the showy French uniform was impossible for modern warfare, and the new cloth, a light, grayish-blue, had been duly selected before the war broke out, though it had not yet been introduced into

the army. But if I can judge from appearances the present idea is that any fellow with the requisite shekels can buy the new uniform if he likes,—or as much of it as he can afford; and the kaleidoscopic result is something wonderful. This new uniform is really uncommonly smart,—incredibly so for French troops. I saw what I took to be a youth of 16-17 come into a restaurant the other night, with everything spunking new, and he really was a sight for the gods. He had two stripes, at his age, if you please, and from the distressing newness of everything, and his killing attitude of self-approbation, there was no doubt but that he was some young daredevil volunteer who had been making things lively in the trenches and had obtained rapid promotion in consequence and eight days' leave in which to show himself to his adoring girl, who was with him,—naturally. But though this fitness obtains with the officers, with the men the sartorial effects are excruciating; but they are all such jolly, unassuming fellows, and so utterly unconscious of how funny they look, that one has to control one's features. There seems to be no standard blueish-gray; every variety and shade can be met. Again, there can be observed every possible degree of mixture with the old regulation uniform. Furthermore, there is no discernible system in color and position for regimental numbers, lapels and stripes. In a word, it is chaos,—and eminently French! What a regiment of these *laissés-pour-compte* must look like, is quite beyond my power to imagine; and, by the way, this strikes me as a not-at-all undesirable result to have obtained, as with this delightful lack of uniformity it seems as though the singling out and picking off of officers by the enemy's sharpshooters will become a matter of great difficulty. In parenthesis it can be said that his success in the present war has simply transformed the French soldier—you would not know him now! He has become a man who needs considerable sidewalk, as he strides by; and he carries himself in an altogether unaccustomed manner. It is not swagger, not even when at 20 he moves along with one arm in a black silk sling and the *médaille militaire* on his juvenile bosom; swagger may come when the more tangible results of the war materialize, but at present it is only what you might call reawakened consciousness, *on est quelqu'un pardi!* We are just becoming aware that we have been living under a nightmare for 45 years, and that daylight is dawning again, *at last!*

More qualified pens than mine have no doubt told you that the feminine uniforms this Spring are to be short and wide in the skirts, with high boots. The ridiculous and dangerous sheath-skirt has suddenly jumped to yards and yards of width; but the shortness of it—Holy Smoke! nearly half-way to the knee. A marked feature of Paris life, this winter, has been the eclipse of the *demi-mondaine*; it would really be curious to know what has become of them all. Still, now and then, on a sunny morning, you will meet one on the avenue,—also very soberly dressed, but still, fashionably. And to see women of 25-35, with their figures rounded at the proper points striding by with their newly-acquired leg-freedom in skirts about long enough for schoolgirls of twelve, is about as ludicrous a sight as one could wish for. French women were at one time supposed to lead the world in taste in dress; but really, their efforts of the last few years,—first the *entravée*, then the sheath, and now the rope-skipping hoyden! One wonders whether their reputation for taste has not been all a misunderstanding. The finest, and at the same time most sensible women I ever saw are those of an isolated valley in the south of Norway, the Saetersdal. This valley is divided by a long lake into a lower half, in communication with the outside world, and an upper half, practically walled-in on all sides by high mountains. In this upper half the language and customs are still those of centuries ago, and among the latter the fashion of dressing is remarkable. Every woman in the region clothes herself exactly alike, old, adult or child,—white homespun on week days, and black on

Sundays. And not only are the body and skirt similar, but the head dress, shoes and stockings also; and this brings me to my point, which is, that for old, adult and girl alike the skirt comes just far enough down to cover the garter. As these women all work in the fields, and the climate is a wet one, it is at once apparent what a sensible costume this is; and as every woman dresses alike, it is equally evident what an amount of jealousy and heartburn they must be spared! But if you could see the effect that centuries of untrammelled legs, together with rational footgear, have had on the gait of these creatures, as well as on the way in which they carry themselves, you would realize the deformities that civilization has imprinted on the figures and movements of our women-kind. I have introduced this digression about my lady-friends of the Saetersdal because I am wondering whether, now that the Paris skirt has begun to climb, we may not, in a Spring or two, be treated to something on the Saetersdal order? But the agonizing question that presents itself is, whether the understandings that will thereby be revealed to an expectant world, will to the same degree be worth contemplation as those of the peasants of Norway.

"S."

A MISSTATEMENT CORRECTED.

ZOOLOGICAL LABORATORY, HARVARD UNIVERSITY,

CAMBRIDGE, MASS., March 29, 1915.

Mr. Editor: In your JOURNAL, Vol. x, p. 224, Sept., 1872, you report, under the head of Medical Miscellany, a case of eight children at a birth. This remarkable instance has found its way into such texts as that of Gould and Pyle, *Anomalies and Curiosities of Medicine*, 1897, p. 153, and into such special papers as that of Wilder on duplicate twins, *American Journal of Anatomy*, Vol. iii, p. 393, 1904. The case is of recent origin and so remarkable in character that it seemed desirable to ascertain beyond a doubt its authenticity. To this end a letter of inquiry was addressed to the county clerk of Trumbull County, Ohio, where it was said to have occurred, with the request that further information concerning it would be gratefully received. The response of this official was as follows:

M. B. TAYLER
CLERK OF COURTS
TRUMBULL COUNTY

WARREN, OHIO, March 30, 1914.

Mr. G. H. Parker,
Cambridge, Mass.

Dear Sir: In reply to your letter of the 24th inst., in regard to the item in the medical journal, would say that after inquiry I am informed that there is no truth in the statement. It seems that a practical joker of those days went into one of the newspaper offices here and set up an article which he succeeded in having printed in one or two copies of the paper and then took the article out and distributed the type in their proper places, and securing the copies which had the article in, sent the same to a New York paper, thinking he had accomplished a great joke. This is practically all the information I can obtain in regard to the matter but can state that there is no truth or foundation in the report whatever.

Very truly yours,
(Signed) M. B. TAYLER.

From the reply of Mr. Tayler, it is quite clear that the case is spurious and I am sure you will be desirous of doing what you can to make its real nature known.

Very truly yours,
G. H. PARKER, M.D.

[The note referred to is as follows: "On the 21st of August, Mrs. Timothy Bradlee, of Trumbull County, Ohio, gave birth to eight children—three girls and five

boys. They are all living, and are healthy but quite small. Mr. Bradlee was married six years ago to Eunice Mowery, who weighed 273 pounds on the day of her marriage. She has given birth to two pairs of twins, and now eight more, making twelve children in six years. Mrs. Bradlee was a triplet, her mother and father being twins, and her grandmother the mother of five pairs of twins."

We are glad, even after this interval of time, to correct so gross a misstatement appearing in this JOURNAL.—EDITOR.]

DIAGNOSIS FIRST, TREATMENT AFTERWARDS.

COLONIAL BUILDING, BOSTON, April 13, 1915.

Mr. Editor: One of my former boy patients whose throat had been operated upon for adenoids, if I remember correctly, but whose ears had not improved therefrom, has recently been infected with the organism which produces pleurisy. Empyema of the thorax has supervened, and the boy, removed to a hospital, has had exsection of a portion of the rib done with "a quart of purulent material" drained away. I do not report this case by proxy, as it were, to hint at the vast amount of practical ignorance remaining in this community, so much as to bring once more to the notice of practicing physicians the name of one of my revered preceptors. Professor Henry Ingersoll Bowditch, who was bold enough to do "thoracentesis" before the days of aseptic surgery and to whom we are indebted for his intuitions regarding appendicitis. How many times have we heard him say, "Gentlemen, I believe you would be justified in opening the abdomen."

"Diagnosis first, treatment afterwards."

EDMUND D. SPEAR, M.D.

CHANGES IN THE MEDICAL CORPS, U. S. NAVY, FOR THE FOUR WEEKS ENDING APR. 10, 1915.

March 13, P. A. Surgeon C. M. George, to Naval Hospital, Newport, R. I.

March 17, Asst. Surgeon C. A. Simpson, resignation accepted to take effect March 18, 1915.

March 18, P. A. Surgeon W. H. Halsey, to Naval Training Station, San Francisco, California.

March 24, Act. Asst. Surgeon M. E. Rose, detached, Navy Yard, Charleston, S. C., to Naval Hospital, Washington, D. C., for treatment.

March 25, P. A. Surgeon, H. W. B. Turner, from *Albany* to Asiatic Station.

March 27, Surgeon A. L. Fauntleroy, detached, Naval Hospital, Washington, D. C., to assistant to Naval Attaché, Paris, France.

March 29, Asst. Surgeon Overton Brooks, commissioned from March 10, 1915.

March 30, Surgeon J. R. Dykes, detached, Naval Recruiting Station, Atlanta, Ga., to wait orders.

March 31, Surgeon J. F. Murphy, to Naval Recruiting Station, Atlanta, Georgia.

P. A. Surgeon H. L. Brown, detached, *Ohio* to *Alabama*.

April 3, P. A. Surgeon G. R. W. French, detached, Naval Hospital, New York, to *Maryland*.

April 5, P. A. Surgeon B. H. Dorsey, detached, Atlantic Reserve Fleet, to Bureau of Medicine and Surgery, Washington, D. C.

April 7, Surgeon W. H. Rennie, detached, Naval Hospital, Boston, Mass., to Naval Hospital, New York, N. Y.

NOTE:—Med. Dir. Michael Drennan, retired, died at Easton, Pa., March 18, 1915.

NOTICE.

TESTIMONIAL BANQUET TO DR. JACOBI.

A testimonial banquet will be tendered Dr. A. Jacobi by the medical profession, his friends and admirers, under the auspices of the Bronx Hospital and Dispensary, on the occasion of the eighty-fifth anniversary of his birthday, on May 6, at the Hotel Astor, New York.

To give the younger members of the profession an opportunity to participate in the celebration and to come in contact with the venerable Nestor of American medicine, the price per plate has been fixed at three dollars.

The medical men on the Committee of Arrangements are: William J. Robinson, chairman; Arpad G. Gerster, Willy Meyer, S. W. Lambert, J. Brettauer, Francis Huber, A. A. Berg, M. Rebling, S. A. Knopf, H. Edwin Lewis, M. Aronson, Otto Schlirmer, Max Rosenthal, Henry Heiman, A. L. Goodman, A. Hyman-

son, Alex. Goldman, A. A. Brill, A. L. Goldwater, H. Schumer, H. J. Epstein.

Communications should be addressed to William J. Robinson, M.D., 12 Mt. Morris Park West. Reservations for seats should be sent to A. L. Goldwater, M.D., Treasurer, 141 West 121st Street.

SOCIETY NOTICES.

NEW ENGLAND PEDIATRIC SOCIETY.—The thirty-eighth meeting of the New England Pediatric Society will be held in the Boston Medical Library, Friday, April 30, 1915, at 8.15 P.M.

The following papers will be read:

1. "Can the Speech Present a Sign of Congenital Syphilis?" W. B. Swift, M.D., Boston.
2. "Acute Otitis Media in Childhood; Avoidable Mistakes in Diagnosis, Prevention, Treatment." W. R. P. Emerson, M.D., Boston.
3. "Studies in Bronchial Glands." W. W. Howell, M.D., Boston.
4. "Endocarditis in Children; Its Prophylaxis and Treatment in an Out-Patient Department." R. S. Eustis, M.D., Boston.

Light refreshments will be served after the meeting.

E. M. BUCKINGHAM, M.D., *President*.
RICHARD M. SMITH, M.D., *Secretary*.

SUFFOLK DISTRICT MEDICAL SOCIETY.—The annual meeting will be held at the Boston Medical Library, 8 The Fenway, Saturday, April 24, at 8.15 P.M.

Owing to the illness of Dr. Theobald Smith, his paper previously announced will not be presented.

Dr. Ernest E. Tytzer, Director of the Cancer Commission of Harvard University, will read a paper on "The Present Trend of Tumor Investigation."

Business: Report of the Librarian, Treasurer, etc. Election of officers.

Refreshments after the meeting.

HORACE D. ARNOLD, M.D., *President*.
WALTER C. HOWE, M.D., *Secretary*.

NEW YORK ACADEMY OF MEDICINE, 17 West Forty-third Street. Section on Medicine, Tuesday evening, April 27, at 8.30 o'clock.

ORDERS

- I. a. *Demonstration.*—"The Introduction of Liquids and Gases Into the Duodenum Through the Duodenal Tube and Their recovery from the Rectum."
- b. "Technic of Intestinal Irrigation." (25 min.) I. O. Palefski, M.D. (By invitation.)
- II. "New Method of Diagnosis and Treatment of Esophageal Stenosis." (Lantern slides.) (15 min.) Armistead C. Crump, M.D. (By invitation.)
Discussion by Drs. S. Wachsmann and Harlow Brooks.
- III. "Digitalis Dosage." (Lantern slides.) (15 min.) Cary Eggleston, M.D.
Discussion by Dr. Walter A. Bastedo.
- IV. "Serum Diagnosis of Tuberculosis." (15 min.) E. Castelli, M.D.

T. STUART HART, M.D., *Chairman*,
130 West 59th Street.
NELLIE B. FOSTER, M.D., *Secretary*,
515 Park Avenue.

THE NATIONAL ASSOCIATION FOR THE STUDY OF EPILEPSY AND THE CARE AND TREATMENT OF EPILEPTICS will hold its fourteenth annual meeting at the Hotel Chamberlin, Fortress Monroe, Va., May 10, 1915.

Immediately following are the sessions of the Seventy-first Annual Meeting of the American Medico-Psychological Association.

APPOINTMENTS.

Dr. Rudolph Höber has been appointed professor of physiology at the University of Kiel succeeding *Dr. A. Bethe* who has been translated to the University of Frankfurt.

Harvard Medical School.—At a recent meeting of the overseers of Harvard College, Dr. John Lovett Morse was appointed professor of pediatrics; Dr. Charles Montraville Green, emeritus professor of obstetrics and gynecology; Alexander Quackenboss, assistant professor of ophthalmology; and Dr. Lawrence Joseph Henderson, assistant professor of biological chemistry. Dr. Robert W. Lovett, Dr. Charles L. Scudder and Dr. Frederick T. Lord, members of the administrative board of the Graduate School of Medicine.

RECENT DEATHS.

DR. CHARLES HAMANT HARWOOD who died of pneumonia on April 11, in Boston, was born at Medfield, Mass., in 1864. He received the degree of A.B. from Harvard in 1888 and that of M.D. in 1892. He is survived by his widow and by one son.

DR. B. J. ANDREWS, who died on April 12, at Burlington, Vt., was born in 1850. He received the degree of M.D. in 1885 from the University of Vermont. He had served since 1890 as superintendent of the Mary Fletcher Hospital, Burlington.

DR. LEWIS WALDSTEIN, who died on April 12 in London, was born at New York City in 1853, and practised there for many years as a physician and pathologist. Recently he had been pursuing scientific research in London.

DR. WILLIAM H. RANDLE, who died recently at Philadelphia as the result of a mastoid infection, was born in 1851. He was a member of the first yellow fever commission appointed by President Hayes in 1878.

DR. DONNELL HUGHES, who died of pneumonia on April 8 at Philadelphia, was born in 1857. He was a member of many medical societies, and was widely known as a gynecologist and obstetrician.

DR. FRIEDRICH LOEFFLER, who died recently at Berlin, was born in 1852. With Klebs he was the discoverer in 1884 of the diphtheria bacillus.

DR. ERNEST P. MAGRUDER, of Washington, D. C., who died recently of typhus fever at Belgrade, Serbia, where he was in charge of the American Red Cross unit, was born in 1875. He was professor of clinical surgery at Georgetown University, and was a Fellow of the American College of Surgeons.

DISPENSARIES: A GROWING FACTOR IN CURATIVE AND PREVENTIVE MEDICINE.*

BY S. S. GOLDWATER, M.D., NEW YORK,

Commissioner of Health of New York City.

THIS is a topsy-turvy world just now, and it is in keeping with the prevailing confusion that someone should come from New York to Boston to give advice about dispensaries. We New Yorkers in reality are but humble disciples of the Boston masters who hold unchallenged the leadership in progressive dispensary work.

I have been requested to speak about dispensaries as a growing factor in curative and preventive medicine. There are two ways in which dispensaries are a growing factor in this field: they are reaching a constantly increasing number of individuals; and they are becoming more effective through improvements in method which may be traced to the inspiring example of such institutions as the Boston Dispensary.

You have in your hands a pamphlet stating that in 1900 there were 100 dispensaries in the country, against 574 reported by the United States Census Bureau in 1910, and more than 700 at present. These figures show roughly the rate at which dispensary work is growing. Dispensaries are bound to increase in number, and they tend to do so at an accelerating rate.

* Delivered at the 118th annual meeting of the Boston Dispensary, January 21, 1915.

During the calendar year ending Dec. 31, 1910, 1,953,309 sick persons were treated in institutions in the United States, of which number dispensary patients formed the greater part. In 1910, 180 dispensaries reported receipts of \$1,069,613, while the property in the possession of 119 dispensaries had an estimated value of \$5,720,052.

More and more will there be various kinds of special dispensaries. There is a law in Massachusetts today which requires in every city of 10,000 or more, the establishment of a dispensary for the treatment of persons affected with tuberculosis. Recent reports show that out of fifty-four towns to which that law applies, only thirteen have complied with its provisions. Now, the passage of this law indicates the official acceptance of the belief that every town of 10,000 inhabitants needs a tuberculosis dispensary; and I suppose that before many years pass, the law will be enforced. When that occurs, there will be in Massachusetts three or four times the number of tuberculosis dispensaries that exist today. This, I confidently predict, will happen within the next decade.

Let me say a word about dispensary work in New York. We have in the metropolis a population of between five and six million. More than three million treatments were given in New York dispensaries last year, and the number of consultations is steadily increasing. It is estimated that nearly 1,000,000 different persons look to dispensaries for treatment. There are twenty-five different kinds of dispensaries in the city, and the various departments, taken together, are open for business between 1100 and 1200 hours each day.

In New York there is a certain amount of dispensary regulation. Dispensaries are required to obtain a state license before undertaking to do business, and it is notable that out of the applications that are presented, it seems wise to the State Board of Charities to deny at least a dozen every year.

I hope the time will come when State regulation in this field will be more rigorous, and will be intelligently standardized. The rules of the New York State Board of Charities are comparatively mild. It is required that those who desire a dispensary license shall give proof of a benevolent interest in the work, as attested at least by the possession of and willingness to spend some of the money that is required to carry on the work in a decent way. When the State Board rejects an application, it may signify that in the opinion of the Board, the motives of the applicant are not wholly disinterested; or granting disinterested motives, that the applicant is lacking in means or ability. There is, therefore, in the attitude of the State Board of Charities some faint glimmering of an appreciation of the need of standards—of proper standards, in dispensary work. But among those who satisfy the scrutiny of the Board, who enter the fold and who actually establish dispensaries, there are not a few who, in the opinion of competent and impartial critics, fail to carry on the work in a satisfactory manner.

If the term "dispensaries" is to be liberally interpreted, there are in operation in various parts of New York State a great many dispensaries which are not classified as such by the State Board of Charities, but which, nevertheless, are doing dispensary work. A dispensary might be defined, in the current sense, as a place to which ambulant patients may come for gratuitous or semi-gratuitous examination, advice and treatment. Many places which correspond to this definition receive no recognition from the State Board of Charities.

In certain of the departments of the government of New York City, medical supervision has been established over employees; this has been done in the police, fire and health departments, where employees are examined, advised and treated without charge when ill. This system is supposed to make for individual and departmental efficiency, and to afford some measure of protection to the municipality's pension system.

In the New York Department of Health, where the medical supervision of employees was instituted only last year, we had a different idea in mind. It is not, primarily, *sick* employees who are examined—all employees are to be examined periodically. We want to prevent and to postpone disease; we hope to take as good care of those who are in the service of the Department as the physical director of a college takes or should take of students in the college; but our work is of greater importance than college work, because it embraces the whole period of the employee's working life. Work of this kind

is bound to develop apace among private, as well as among government, employees.

There are in New York City, and elsewhere, mercantile and manufacturing establishments in which there exist emergency treatment rooms. These are industrial "accident" dispensaries. Out of these little dispensaries there will come, in the course of time, a broad movement for safeguarding the health and promoting the welfare of workers. Unless I am much mistaken, there will develop out of these accident rooms a system of periodic physical examinations, so that insidious chronic diseases, whether related or not to occupation, may be discovered at the earliest possible moment and be checked before great and irremediable harm is done.

Another dispensary type which merits attention is the babies' consultation room or milk station. Milk stations are multiplying rapidly. Fifty-seven such stations are conducted by the Department of Health of the city of New York. Here mothers are taught how to care for their children according to the laws of hygiene.

In many localities medical care by lodge doctors is the chosen or established method of dealing with sickness among the relatively poor. I am told that in your own city of North Adams, with a population of 22,000, 8,000 persons are in the care of lodge physicians to whom the members pay an annual stipend for medical care. One might ask whether the lodge doctor is a satisfactory substitute for the dispensary. Where lodge doctors flourish, is it desirable that a dispensary be established?

I have no deep-rooted objection to lodge doctors. Among them are many competent medical men; and between the slipshod service of the poorer kind of dispensary, and the painstaking care of the conscientious lodge doctor, the choice easily lies with the latter. A lodge doctor, however, has this limitation; he is only one man; he can acquire, therefore, only that degree of medical knowledge and skill that it is possible for a man to acquire who is engaged in the general practice of medicine. He is not able to compete in knowledge or in skill with a co-ordinated group of specialized physicians, surgeons, and pathologists, working together in a comprehensive organization. Since, in comparison with such a group, the lodge doctor's capacity is necessarily inferior, we must declare the dispensary to be the better plan for dealing with many ambulatory patients of the poorer kind. That the lodge doctor is paid for his service and the dispensary doctor, as a rule, is unpaid, is an important matter, especially to the doctor; but this is a question to be treated separately on its own merits, and should not influence our decision of the question which is here under consideration.

Beginning next year, New York will require the names of the ingredients of patent medicines to be given on the labels; or else that the names of the ingredients be filed with the Board of Health, which will examine and pass upon the reasonableness of the therapeutic claims which

are made on behalf of the respective preparations. The representative of a large retail drug firm recently told me that the business of his firm in Boston alone amounts to \$3,000,000 a year, largely in patent medicines. Now I am ready to admit that whether a man will run the risk of using a secret remedy, or will prefer the advice of a qualified physician, is partly a question of his intelligence and mental training; but much depends and will always depend on the accessibility, the cost and the quality of medical service. Legitimate medical practice will gain ground in proportion to its quality and its availability. A large number of the comparatively poor now resort to self-medication, lured by unscrupulous and indiscriminating catch-all advertisements; but as people are gradually taught to appreciate the dangers of self-diagnosis and self-medication, the demands on dispensaries will be increased, and their resources, however great, will be found to be inadequate.

Dispensaries are growing in number, in capacity, and in variety, and this growth is stimulated by various factors, some of which have been mentioned. Are dispensaries growing in effectiveness?

We are told that when a man sets up in Germany as a teacher of philosophy, he spends some years at the feet of the great masters, and eventually adopts as his own that system or method of philosophic thought which appeals to him most strongly. Before beginning to teach, he enunciates his theory and method. Before analyzing dispensary work, one ought to have some years of experience, and then adopt a plan—a system of approach. Shall we approach the subject rationally or empirically? If rationally, we shall have to begin with some general principle, and test dispensaries accordingly. Now, following this method, I must begin with the confession that, in principle, I am devoted to the *hospital* dispensary; I think it imperative that a dispensary, in order to reach maximum efficiency, shall be associated with a hospital. But I hesitate to declare my belief in this principle because the Boston Dispensary is not a hospital dispensary (with the exception of its children's department), and yet is recognized as perhaps the most progressive dispensary in the United States today.

However, the hospital dispensary has undeniable advantages. There are open to the dispensary which is attached to a hospital opportunities which are denied to the independent dispensary. If a patient comes to the hospital dispensary and is found to be in need of hospital treatment, he can be admitted to the hospital promptly and directly, and the dispensary staff can follow the case to the wards. Cases can thus be handled in continuity from start to finish, either by one man or by a group of men working in harmony. Moreover, hospital patients can be sent to the dependent dispensary and its social service department for after-care. I need not expand this argument here; but I think it worth

while to say that it is really remarkable that the Boston Dispensary has attained its almost unrivalled position in the dispensary field, in spite of the fact that it is not, except in relation to its children's department (and there only recently), a hospital dispensary. There must be reasons for this. What are some of the reasons?

One reason for the success of the Boston Dispensary is the fact that it has sought to appraise its own work honestly. You have been able to see and willing to admit to yourselves and to others, the things which you were *not* doing, and which, you believed, ought to be done. A dispensary of the average sort makes much of the fact that so many patients come to it each day or each year. The Boston Dispensary, however, was the first, or one of the first, to inquire how many patients failed to return after the first visit, and to ask why such patients did not come back. If I correctly understand the point of view of your Director, whose enthusiasm for the work has meant so much to all of us, the failure of a patient to return for needed treatment is regarded as discreditable to the dispensary. The Boston Dispensary, then, has excelled in patient and illuminating self-analysis.

Moreover, the Boston Dispensary was one of the first dispensaries to recognize the interdependence of medical and social work. It has long been known that there is a connection between environment and disease. The study of occupational diseases was inaugurated at Padua hundreds of years ago. From time immemorial, the clinical history forms used in hospitals almost everywhere, have included a line for the recording of the patient's occupation, but this record was made in routine fashion. It meant absolutely nothing. Oftentimes it was not even an accurate characterization of occupation, and was valueless for any statistical or scientific purpose. You approached these matters in greater earnest; you realized that the patient's social and occupational history was a factor of genuine importance, and perceiving that the dispensary could rarely cure and almost never prevent disease by mere drugging, you proceeded to build up an organization in which medical work and social work have been effectually correlated.

You have sent your nurses and social workers into the homes of your patients, and have thus accomplished much for the patients as individuals. Are you going to stop there? Working with your patient as an individual, you try to alter his habits or to improve his environment so as to favor his recovery from disease, and to facilitate the maintenance of his health subsequently. All of this is well worth doing. But are you willing to stop there? Isn't there something else that cries out to be done? I believe there is.

If a hundred patients should come into your dispensary, presenting some common symptom and giving a history of a single occupation, your social workers would speedily notice the correlation between disease and occupational habit. In

fact, large numbers of patients engaged in a single occupation or exposed to the same environment do not come to the dispensary together, but in such scattered fashion that it is not very easy to discover the common factors in a large group of cases. Nevertheless, in the background there are common environmental conditions which need to be treated in themselves, with a view to disease prevention. May not the dispensary, which in its records of thousands of cases possesses the key to these conditions and can show the harm they do, properly concern itself with environmental treatment, with social conditions, with social reform?

It may seem a far cry from dispensary work to the single tax, yet the Surgeon-General of the United States Army *advocates the single tax on land as a health measure*. Col. Gorgas believes that an important cause of disease among the poor is overcrowding in habitations; it is his theory that the single tax would lessen congestion, would distribute the people over the land, and would thus minimize disease. You see he does not deal with disease in the orthodox way; he goes after what he believes to be the underlying cause and combines political economy and constructive statesmanship with sanitation. We may or we may not agree with his political economy or with his theory of taxation; we cannot fail to commend his plan of bringing within the field of sanitary observation concealed factors which he believes to have an indirect but a real relation to disease; and we must admit that such broad vision as this makes even the admirable and effective social work of the Boston Dispensary look very small.

The Boston Dispensary has done more clinical team work than the average dispensary; it has linked its work with that of the medical schools; it has persistently and effectively associated the medical and the social worker. Let me refer briefly to each of these things.

"Clinical team work" is a phrase that is in everyone's mouth nowadays. Where and to what extent is clinical team work demanded? Organized or institutional medicine, the medical practice of associated specialists, tends to supplant the private doctor, because where a man works alone the advantages of team work are lacking. The growing complexity of medicine as science and as art, calls constantly for more team work.

The most complete expression of medical team work is found in the large general hospital; if properly managed, such a hospital commands the best talent and the best equipment in the right proportions and in the most effective relations. One large and complete general hospital is better than several small hospitals, because the very small hospital cannot have a first class laboratory organization, nor a clinical organization full enough to permit clinical team work to be developed in the highest degree. In the general hospital, and in the general dispensary in

which the clinical departments are organically related, there is clinical team work in its most admirable form. In most of our cities, the benefits of this service are available today for the very poor and for the rich.

Unfortunately, the facilities of general hospitals and dispensaries are not widely available at present for the patient who is just above the poverty line; yet such patients form the most numerous class in the community. Should not an effort be made to place efficient medical organizations within the reach of this class? Forty New York dispensaries were recently invited to enter this field, and all declined. The Boston Dispensary, however, has made a beginning with its self-supported evening clinics.

The organization of clinics for self-supporting working people is just now especially important because of impending social legislation. Such organization will facilitate the introduction of state-regulated sickness insurance, and will add to the value of such insurance when established. Great Britain launched its insurance scheme before adequate preparation was made. The great voluntary hospitals and out-patient departments of London, where much high-grade medical work is done, but done gratuitously, were not incorporated in the government's plan; the medical care of the insured was left to district or panel doctors, with their necessarily limited knowledge and inferior facilities for diagnosis and treatment. A medical organization which is fathered by the government should be on a higher plane of efficiency; and in order to insure the best results, the principles of team work must be utilized.

Now that this country is moving toward sickness insurance, I hope that we shall be foresighted enough to utilize in whatever plan we may adopt, the available resources of our existing medical institutions, both hospitals and dispensaries; without this, we cannot provide medical service of the best kind. Of course the present facilities will have to be greatly increased; and since the medical work will no longer be charitable work, but part of a scheme of social insurance, adequate compensation will have to be provided for the doctors.

You ought to have in Boston, for the study of these problems, a strong organization representing all of the respectable dispensary elements. It is of vital importance that the dispensaries get together and agree upon proper working methods. Such an organization would find, I dare say, that much more money should be invested in dispensaries. It would be a splendid thing if you could establish a central fund, to be distributed among dispensaries in proportion to their needed service. A central organization with cash resources could do much to promote the standardization of dispensaries upon sound principles. This is a task which in New York may be undertaken in the near future by the Hospital Saturday and Sunday Association,

whose trustees have the matter under advisement.

I should like to say a word in relation to teaching. The dispensary has a well recognized place in medical education. Time was when medical students were brought into clinics chiefly for the study of normal physical signs. There may have been some benefit to the students in this, for the physician must familiarize himself with normal signs before he can intelligently differentiate the signs of disease. But the student in the older days was interested in the patient's body—not in the patient. The student who enters the dispensary today finds himself in a different atmosphere; in a dispensary like yours, the student cannot fail to have his attention directed to the patient's individual character and needs, and to the social aspects of disease as well. With your aid, the student acquires a knowledge not only of curative medicine, but of some of the most important aspects of preventive medicine. As a teaching institution, therefore, the dispensary has distinctly improved.

Certain types of dispensaries are essentially teaching institutions. The so-called milk stations are mothers' schools, where infant hygiene is taught. Besides instructing mothers in the care of their children, milk stations should be used as centers of inquiry for the purpose of ascertaining and making public social facts that have a bearing on infant mortality. A recent survey of a district in New York showed that 45% of the fathers of the registered children were not regularly employed, and that 65% of the mothers worked outside of the home to help support the family. Under such circumstances it is not surprising that infant mortality in this district reaches the appalling figure of 340 per thousand—more than three times the average for the city as a whole. May we not look to general dispensaries as well as to milk stations and tuberculosis clinics, to make it one of their principal objects to disclose such facts as these? Under the influence of such work, dispensaries will soon perceive the desirability of close co-operation.

In New York certain conditions are characteristic of special sections. The various racial groups often settle in localities which they make peculiarly their own. In many cities there are districts where nearly everybody is engaged in one industry. Where such conditions exist, social studies would be facilitated by a comprehensive municipal organization of dispensaries on the district plan. Obviously the existence of independent dispensaries presents obstacles to a co-ordinated district plan. For various reasons, voluntary institutions are unwilling to agree to a district system; for instance, a dispensary may fear that its appeal for contributions would carry less weight, if patients were accepted from a limited district only, instead of being permitted to come from anywhere. This particular fear, by the way, has been shown to be ground-

less; but the idea persists; and the voluntary dispensaries continue apart, handicapped themselves by their separation, handicapping each other and the municipal dispensaries with which they decline to associate.

From the standpoint of social organization rather than that of individual service, there are certain advantages in the public as against the private management of dispensaries. Without doubt, the dispensary work of a city should be broadly planned, and this is most readily done when the work is regarded as a municipal or public function. But the United States is far from ready to discard voluntary hospitals and dispensaries. Present plans, therefore, should aim at the co-ordination of voluntary and municipal dispensaries; the two groups should work together in a serious effort to meet the needs of the hour: each will profit by contact with the other, but the community will profit by the partnership most of all.

Prof. Münsterberg recently said that social unrest could be done away with, if the problem were handled by psychologists; that what the discontented worker needs is not more of this world's goods, but a different view-point, which the psychologist could easily implant. Münsterberg would strive to make the discontented factory hand who receives \$5 or \$6 a week, realize that he is part of the great social machine that is working out the evolution of the race. What the poor need, in other words, according to Münsterberg, is not more bread, better clothing or improved housing, but an inspiring social philosophy. That happiness is a subjective, not an objective, state, may be admitted; but no social philosophy, however altruistic and optimistic, will produce universal contentment.

The dispensary worker needs a social philosophy, not to make him happier, but to accentuate his earnestness. He should sympathize with the patient as an individual; but also he should see the patient as a part of the social body, and with this vision before him, he is certain to redouble his efforts, and to direct them into more useful channels. In proportion to the clearness of his social vision, will the emphasis in his work be placed on preventive rather than curative medicine.

The broad aim of preventive medicine is to make normal living possible for everybody. If conditions of housing, work, food or recreation are unfavorable to the attainment of this ideal, the dispensary must uncover the facts, denounce the evil, and help to secure the application of the remedy. No other institution is more advantageously placed for purposes of social observation; hence it is the peculiar duty of the dispensary to participate in constructive social reform. Upon suitable occasion, the dispensary must not hesitate to sound the social fire alarm: society will heed the warning if the note is sounded clearly.

CARE OF PROSPECTIVE MOTHERS.*

BY ARTHUR B. EMMONS, 2d, M.D., BOSTON.

OUR new Health Commissioner of Massachusetts, Dr. McLaughlin, is pointing out that a health department to be effective must be efficient in all its parts. These parts, he says, include not only the State Department and local boards, but the physicians, the nurses, and the people themselves. Public health must begin with the individual and the family. Their teachers are the nurses who must depend on the doctors for their knowledge of hygiene. It is in your capacity of family health officer that I wish to address you doctors to-night.

My subject, "Care of Prospective Mothers," is a part of preventive medicine. Pregnancy care, intelligently and systematically given, I shall try to show, leads to better obstetrics, and thus adds to the safety of child-bearing, which is a most vital branch of public health. Is there need of improvement in this branch of public health? Or is it on a satisfactory basis now, not only among our well-to-do patients, but among the poorer people? I quote from some of our highest authorities in this country, who go to the root of the matter, the teaching of obstetrics in the medical schools throughout this country.

Dr. J. Whitredge Williams, professor of obstetrics at the Johns-Hopkins Hospital, through a questionnaire sent to the professors of obstetrics throughout the country, indicates the condition of affairs in part as follows:¹

I. Many of the professors are poorly prepared for their duties and have little conception of the obligations of a professorship. Some admit that they are not competent to perform the major obstetric operations, and consequently can be expected to do little more than train man-midwives.

III. Many of them admit that their students are not prepared to practice obstetrics upon graduation, nor do they learn to do so later.

V. Reform is urgently needed, and can be accomplished more speedily by radical improvement in medical education than by attempting the almost impossible task of improving midwives.

VI, c. Recognition by medical faculties and hospitals that obstetrics is one of the fundamental branches of medicine, and that the obstetrician should not be merely a man-midwife but a scientifically trained man with a broad grasp of the subject.

d. 5. Education of the general practitioner that he is competent only to conduct normal cases of labor, and that major obstetrics is major surgery, and should be undertaken only by specially trained men in control of abundant hospital facilities.

e. Education of the laity that poorly trained doctors are dangerous, that most of the ills of women result from poor obstetrics, and that poor women in fairly well conducted free hospitals usually receive better care than well-to-do women in their own homes. Teach that the *remedy lies in their hands*, and that competent obstetricians will be forthcoming as soon as they are demanded.

f. Urge the extension of obstetric charities—free hospitals and out-patient services for the poor, and proper semi-charity hospital accommodations for those in moderate circumstances.

g. Greater development of visiting obstetric nurses, and of helpers trained to work under them.

h. Gradual abolition of midwives in large cities and their replacement by obstetric charities. If midwives are to be educated, see that it is done in a broad sense and not in a makeshift way. Even then disappointment will probably follow.

This all comes from the professors themselves. Hear what another professor says of present conditions throughout the country: "Dr. De-Lee" of Chicago in discussion said: 'Medical education in the department of obstetrics in the United States is below the standard maintained by the teaching of other departments, and continues to cry loudly for improvement. There is no question but that the medical men in the United States are not prepared to cope with obstetric emergencies. I feel that the statement cannot be controverted that there *die* in the United States, as direct and indirect results of childbirth, *20,000 women annually*. If we think what a furor would be raised in the community if yellow fever were to take off 20,000 human beings in one year, and on the other hand contemplate the equanimity with which the public views this annual loss of 20,000 mothers, the comparison is striking.

"We cannot measure the amount of *suffering and invalidism* entailed by bad obstetric practice, but to one who views the procession of maimed and sick women that enter our hospitals, seeking relief from the diseases and accidents of childbirth, it is heart rending.

"*Hundreds of thousands* of babies are permanently crippled, either mentally or physically, as the result of improper obstetric management at their births, and in a goodly proportion the infant becomes *blind* as the result of carelessness.

"What is the cause of all these miserable conditions? There is but one answer. *The standard of obstetric teaching* and obstetric practice in the United States is *too low*. The public has no respect for the obstetrician. He is looked down upon, not alone by the people, but by the doctors themselves. The people will not pay the obstetrician properly for his arduous work. Obstetrics is the hardest branch of medi-

* Read before the Cambridge Medical Improvement Society, January 25, 1915.

cine to practice. It robs the doctor of his sleep, destroys his office hours, interferes with all his engagements, and besides that, the actual work is exceedingly laborious."

Another aspect of the question was expressed by Dr. S. Josephine Baker,³ director of Child Hygiene, Department of Health, New York. She says in part: "No amount of legal enactment for mere control after licensing and no amount of mere supervision, however faithfully carried out, will ever solve the midwife problem. If we are to meet and master the situation,—and the need of such a course is imperative—we must insist that every midwife receive an adequate professional training before she is allowed to practise, and we must provide the proper schools for this purpose."

Dr. Baker was one of those chiefly interested in establishing the Midwife School at Bellevue Hospital. She had the direct control of the large number of the midwives in New York City in 1911, 1344 permits, 51,996 births (40%) conducted by them. She has done a wonderful piece of work in bringing them to a higher level of efficiency and safety.

This, undoubtedly, is a temporary solution of the immediate deplorable situation in New York City where the midwives care for at least 50,000 births annually. The midwife system however must at bottom rest on the medical profession for the care of all abnormal cases. The cases treated by the midwives are lost to science and for teaching, and a second standard on a different level is established. An important branch of surgery is removed from the medical profession. *Is the medical profession ready to delegate normal obstetrics to the midwife?* Or are physicians ready to take the trouble, care, and expense of some other means to care, at an equal or nearly equal price, for these women?

From these statements it seems fair to conclude that the present system of caring for poor women is being shown to have failed to give reasonably safe care. If the medical profession does not face the difficulty and overcome it, various social forces are likely to demand an improvement by some means.

All this goes to show a general dissatisfaction, backed by statistics, of our present methods of caring for prospective and parturient mothers. How is it possible to better these conditions in our own city? I am here tonight to present one scheme—the *pregnancy clinic*. What does this mean? It means conserving the health and strength of the prospective mother; it means foresight and forehandedness during pregnancy. A common practice among the unenlightened or improvident, who blindly hope all is well, is to call at the last minute a doctor or midwife to meet unprepared any emergency. Pregnancy care substitutes for this haphazard method the following procedure:

The doctor sees the prospective mother as soon as she suspects that pregnancy has oc-

curred. He learns the history of past illnesses and childbirths and her present symptoms. He makes a careful physical examination of the teeth, lungs, heart, and blood pressure, of the abdomen with estimate of the period of pregnancy, the size and position of the child, if near term, the rate and location of its heart, and careful measurement of the mother's bones to make sure no obstruction to birth is present. Swelling of the feet and legs is noted, and a urinary test of the kidney function is made. The facts thus gathered form a basis on which to predict the outcome.

Such prediction is the highest point of obstetric science, and to be reliable, must be made by a physician familiar with the experience of the past. Our medical fathers classified millions of cases and studied thousands of abnormalities. The physician must be prepared to use this knowledge. The judgment of such a man must be balanced by the experience of successfully meeting the many problems and emergencies of obstetrics. How does this help the mother? Here is one example: Professor Kerr of Glasgow, a few years ago, in the Maternity Hospital of that city, by using more exact methods, such as careful study of the pelvis and the size of the child's head, was able to reduce the number of forceps operations, where the pelvis was mildly contracted, from 91 to 47%, thereby reducing the infant mortality in such case from 18 to 2%, and the infant morbidity from 30 to 4%. Similar results have been obtained in this country by Williams at the Johns Hopkins Hospital. Are such results obtained in private practice? I leave it to you doctors to judge whether such study of *private cases* is being made today. Is it possible in the life of a busy general practitioner? With the usual fees paid for obstetric care, can he afford to spend the time for such careful study?

In many cases this preliminary study and care may seem a needless precaution. There are, however, many dangers and discomforts which may by early recognition be avoided. The most important of these are:

1. Contracted pelvis.
2. Difficult labor from disproportion of pelvis and child.
3. The toxemias of pregnancy.
4. Extra-uterine pregnancy.
5. Placenta previa.
6. Pyelitis.
7. Septic conditions, including gonorrhea.
8. Syphilis.
9. Tumors.
10. Intercurrent disease, as heart troubles, tuberculosis and malnutrition.

With the outcome intelligently predicted, the mother is confidently reassured and instructed in hygiene, and the nurse is put in charge of the case, with the doctor as consultant to guard against any abnormal condition which may yet develop during pregnancy. The nurse visits the

home at intervals of not over ten days. At the first few visits home conditions are seen and instruction given for personal hygiene in diet, baths, clothing, fresh air, sleep, and exercise, i.e. how best to conserve her strength for the good health of the baby and for the physical strain of labor and nursing. Later, necessary preparations for the coming of the baby are assured, with every precaution against infection to mother and baby. At all visits the mental and physical condition of the mother is critically observed, a urinary test is made, and the coöperation of the whole family is solicited. The dangerous advice of the gossiping neighbor is less likely to be followed. Experience shows that the tactful nurse is welcome in the home and her opportunity for good is great. It would be difficult to exaggerate the value of these visits, made by an efficient, sympathetic nurse to certain prospective mothers. Seldom will a nurse's personality tell more than in some of these friendly visits. Her social service training will often be invaluable in meeting the situation.

The problems of maternity and its relations with society are enormous. Scarcely a pregnant patient comes to our clinics today who is not worried by some social difficulty added to her physical burden. Such problems as illegitimacy, drunkenness, and desertion are frequent, while improvidence, unemployment, and a too small budget are the usual state. The pregnancy clinic attempts to meet these difficulties through the organization and coöperation of the nurses and social workers. Is the general practitioner prepared and able to do this?

To sum up, pregnancy care is *preventive medicine as applied to obstetrics*, i.e. the utilization of every known means to keep the prospective mother well and strong, to foresee and forestall dangers, intelligently to provide for confinement. This may be merely proper care in the home at a minimum expense for the normal case, or the best skill available in a hospital for averting tragedy. Preventive obstetrics thus includes a wide knowledge of the *anatomy, physiology, psychology, and sociology* of the patient.

To obtain the greatest efficiency in pregnancy care there must be coöperation of the doctors, nurses, milk stations, hospitals, boards of health, and the patients and their families. Before turning to the immediate subject of the local situation, I wish to call your attention to a piece of work which has resulted in the lowest known infant mortality, and "*infant mortality*" has been said to be the most sensitive index of the civilization of any locality. This *most civilized place* is not in Europe or America, but in New Zealand.⁴ While Boston has an infant death-rate of over one hundred, and Massachusetts of 130 and over, New Zealand has a rate of fifty-one, and the city of Dunedin a rate of thirty-eight.

This has been accomplished in New Zealand primarily through the initiative of Dr. F. Truby

King by means of the New Zealand Society and its public health nurses. Dr. King considers that pure milk represents a small part of the improvement which has been accomplished, while the *teaching of mothers* prenatally, postnatally, and later through the milk station, represents a far larger part in the improvement. He has made an *educational campaign*.

Improvement may also be shown to a less extent much closer home. In the city of New York⁵ an experiment has been carried on by the New York Milk Committee, supported by private subscription. The two diagrams show, first, the need of pregnancy care (a still-birth rate in 1910 of 48.1 per 1000 births, an infant mortality under one month of 40.6 per 1000 live births), and second, the result of a considerable experiment of reducing infant mortality by pregnancy care, including the supervision in less than 2 years of 2644 mothers. (This resulted in a reduction of the still-births of 11.2 per 1000, and of the rate under one month of 10.8 per 1000 live births.)

I wish here to describe an experiment carried on in Boston.*

From April, 1909, a committee of the Women's Municipal League of Boston, under the leadership of Mrs. William L. Putnam, has in five years given pregnancy nursing care to 1512 women in Boston. The results have been truly remarkable. No death occurred among these mothers during pregnancy, and but nine maternal deaths at confinement in the hospitals, —0.6% in the full five years.

In the last three and one-half years no miscarriages.

Impending eclampsia: 60 the first year, 2 the last year.

Only four cases of real eclampsia have developed.

Stillbirths, including premature births, were for two years less than half that of the rest of Boston.

Infant deaths: Total number under one month of age, 43, or 2.8%, while Boston's rate in 1913 was 4.3%.

Percentage of breast-fed babies, 84.7%; percentage of mixed feeding, 4.5%; total, 89.2%.

After this five-year experiment the committee rests satisfied that pregnancy care by the nurse visiting in the home at intervals of not-over ten days has demonstrated its efficiency in relieving suffering and preventing danger and disease to the mother, and rendering maternal nursing more successful, thereby reducing infant mortality.

Proceeding from this convincing demonstration, the committee, backed by an advisory board of experienced obstetricians, has undertaken the next step. That is the more difficult problem of medical supervision during pregnancy and adequate care at childbirth. Two dispensary preg-

* Experiment of the Committee on Infant Social Service, now changed to Committee on Pregnancy and Obstetric Care of the Women's Municipal League of Boston.

nancy clinics are under the committee's supervision, one at the Peter Bent Brigham Hospital, the other at the Maverick Dispensary in East Boston.

These clinics are under the direct supervision of an obstetrician. They use as a basis to work with, not the trained or untrained midwife, but the young obstetricians who are graduates of some maternity hospital, and the nurses of the Instructive District Nursing Association. For such an organization semi-free and free hospital beds must be available. We know that at any time during pregnancy the case may demand major surgery. The work is gradually being standardized. For example: No patient before confinement may be visited by a nurse more than twice unless she has been examined by a private physician or by the obstetrician at the clinic. Thus the medical responsibility is carried by the doctor, which the committee feels is essential for the best results. Such a system is designed to use the ever increasing medical and nursing knowledge available in any community and to stimulate this to its highest efficiency. Results are encouraging, but not yet sufficiently numerous to warrant generalization.

THE SITUATION IN CAMBRIDGE.

Cambridge is to be congratulated on its excellent district nursing association. The directors of this association have recognized that a nurse is needed in the home at childbirth fully as much as at any other time. Few district nursing associations have succeeded in overcoming the difficulties involved in caring for obstetric cases in their homes. The irregularity of hours, and frequently the length of time required to care for such cases has made the expense so burdensome that other district nursing associations have shrunk from the task. I am told that in Cambridge every emergency has so far been met. It is recorded that during one rainfall of babies the whole nursing staff was used on obstetric cases; but it is their just pride that they cared for every case.

I am also informed that the physicians in Cambridge, in spite of poor pay and the other burdens of obstetric care, have generously responded to the call of the rich and poor alike, and thus have continued to meet the traditions of the medical profession, and I have no doubt this has entailed a considerable burden on many physicians, for obstetrics today among the poor is not a profitable business.

To demand or even expect more time, study, and care from these physicians with no extra compensation would hardly seem just and right, and yet there is a considerable number of cases. I am informed, where large benefit to all concerned might result if a pregnancy clinic were established. To give, perhaps, the worst possible example, I cite the following case:⁶ The Conviction of a Midwife; Commonwealth vs. Connor.

Catherine Connor was convicted on July 28th in charges connected with the blindness of a baby. Two mothers, one of them the mother of the blind baby, testified that Mrs. Connor had attended them in childbirth. In so doing she had practised obstetrics, a recognized branch of medicine, and not being a registered physician she had thus violated the Medical Practice Act . . . Mrs. Connor had seen the baby's eyes red and swollen and showing an unnatural discharge. Having "seen many such cases before" she provided a brown medicine which she dropped into the baby's eyes, thus again practicing medicine without a license. She also failed to report the birth until legal procedures had been begun, thus violating the Registration Law. She failed to report the symptoms of ophthalmia neonatorum, thus again violating the law. The court found her guilty. On request of the prosecution, and because of the defendant's extreme age, 84, sentence was suspended, on the understanding, however, that the defendant would absolutely give up practice.

The blame for such conditions cannot be laid at the feet of any responsible person, least of all to the medical profession, which has always been ready to care for such cases. Society must, however, recognize that such conditions exist, and it is the hope of some of us at least that the presence of an organized pregnancy clinic in the community may reduce the likelihood of such deplorable happenings. It is our hope that the general level of obstetric care, particularly in the poorer districts, may be raised to what could be fairly considered a service of reasonable safety to those of limited means. Such a project has, therefore, been prospected.

It has been suggested that a clinic be established, holding a weekly conference at the Cambridge Neighborhood House, that the Committee of the Women's Municipal League, whose object is to develop such work about Greater Boston and to stimulate it elsewhere, be responsible for the management, together with the District Nursing Association, whose nurses will carry the work into the homes after being present at the weekly conference, and with the aid of the social forces of the Neighborhood House. Such a project seems to me most favorable for carrying on a work of this character, designed for the good of the community and directed particularly to the better care of prospective mothers. Such a project, however, must have support. It is the hope of those interested that this medical society will give us moral and professional backing. Its very name, the Cambridge Medical Improvement Society, encourages us to this conviction.

Such a project must also have financial assistance. To establish a service which requires considerably more time of trained workers, where already financial stress has reduced the compensation below a profitable basis, means that such a service must be run at a considerable loss.

Any new project involving more expense to those of limited means, even though it may bring better service, is bound to be a losing business. Those interested already recognize this feature and are making preparations to appeal to the community, especially to the women of the community, for at least partial support. The plan is not to give such service free, but to urge all patients to pay the cost, probably from \$10 to \$15 for complete nursing and medical care, or perhaps \$5 where the patient has her own private physician. The obstetrician's time at the clinic will be given free by the committee of the Women's Municipal League. Our experience in East Boston during the first year of that clinic, where patients were asked to pay \$10.00, was that we received an average of a little over \$7.00. This is probably a greater proportion of the worth of such service than is paid by the students at Harvard College toward their educational advantages. Thus we do not consider that we are in any way pauperizing the community.

I began by saying that I wished to speak to you doctors tonight in your capacity of public health officers, and I believe that this project will appeal to the medical profession in this special capacity. It is easy to prove that the occupation of being an infant in Boston is more dangerous today than that of being a soldier in the European War. It has also been shown that 42% of this infant mortality takes place within the first month of life, which represents the large factor that prenatal and birth conditions play in this high infant mortality.

Two views of meeting the problem of reducing this early infant mortality are being put on trial throughout the country. First, the education, licensing, supervision, control, and re-education of the midwife to handle normal obstetrics. The other, to improve the teaching of obstetrics in the medical schools and to develop the maternity service to the community, *i.e.* lying-in hospitals, out-patient and pregnancy clinics. This scheme preserves to the medical profession the care of women at this critical period of their lives. The midwife program is probably the cheaper. The pregnancy clinic, working through the doctors and nurses, retains for the medical profession the care of such cases. In backing such a scheme as has been outlined here, you thereby help to preserve to the medical profession its privilege of rendering intelligent aid to civilized woman at her most critical time of life. I have complete confidence that neither time, effort, nor money will induce you to give up such a privilege.

Original Articles.

PERFORATION OF THE STOMACH AND INTESTINE BY FOREIGN BODIES THAT HAVE BEEN SWALLOWED.*

BY F. S. WATSON, M.D., BOSTON.

I HAVE selected the subject of this communication to present to you this evening, partly because I happen to have had six cases of the condition in my care, partly because some of their features interested me, and partly because I did not recall its having been brought before any of our medical associations here for discussion.

In order to bring the communication within the limits appropriate for the occasion, I have not attempted to treat the subject exhaustively and have confined my exposition of it to a sketch and to the mention of some of its more essential features. I have also restricted it to perforations of the stomach and the intestine, omitting cases of perforation of the appendix or Meckel's diverticulum, of which all of us have doubtless had a good many. I will briefly refer to my own series of six cases first, and will conclude by calling attention to some of the features of the subject in general.

The perforating bodies in my own series of cases were as follows: 1. A wooden toothpick. 2. A needle such as is used in sewing canvas. 3. A fish bone. 4. A bristle. 5. A flat, thin bit of bone with sharp edges. 6. A body of unknown nature, having the shape of a bit of lead pencil, and about an inch and a half in length.

Four of these bodies I have brought with me to show to you; the other two, I regret, were lost.

Sites of Perforation. The sites of the perforations were located in three of the cases. In these they were: In the upper part of the jejunum, in the small intestine near the ileo-cecal valve, in the transverse colon midway in its course. In two of the remaining three they were presumably high up in the intestinal tract or in the stomach, and in one of them in the small intestine near the ileo-cecal valve.

Pathological Processes Produced by the Perforations and Foreign Bodies. In all but one of the cases the pathological conditions discovered were those that are seen in circumscribed peritoneal infection and inflammation.

In three of them intra-abdominal abscesses had been formed. In one of these the abscess had approached the surface of the abdomen, and would doubtless have been spontaneously evacuated there had not the operation been done.

In the second example of intra-abdominal abscess, that in which the jejunum was perforated, the conditions were of a more acute and severe grade of local peritoneal infection. The perforation in the bowel was large enough to admit the tip of the little finger, and fecal extravasation

* Read at the meeting of The Boston Surgical Society, March 1, 1915.

was taking place from it into the cavity of the abscess. The process was but five days old in this instance.

In the two cases in which the perforations were in the small intestine near the ileo-cecal valve, the areas around the sites of the perforations were well walled off from the peritoneal cavity by adhesive processes. An illustration of the condition seen in a good many of these cases was afforded by the toothpick case. Here the foreign body had evidently but very recently perforated the bowel, nevertheless, the immediately adjacent area was walled off by adhesions that had been formed before the perforation actually took place.

In the transverse colon perforation and in that caused by the bristle the conditions presented were somewhat unusual. In the former there was a tumor about the size of the palm of my hand, projecting above the surface of the abdomen somewhat, at the level of the umbilicus and extending downward toward the upper margin of the symphysis pubis in less conspicuous form.

This tumor represented an enormously thickened portion of the left rectus abdominalis muscle which at its thickest part must have measured two inches in depth. Immediately beneath this was a mass formed by the thickened omentum which was intimately attached to the parietal peritoneum overlying it, and which extended upward and downward. Beneath and below this mass was a second one, the lower border of which reached the level of the brim of the pelvis and extended toward the spine posteriorly. This mass was an intra-abdominal abscess containing about twelve ounces of pus and the foreign body. The three parts just described were welded into one mass which gave the impression of a large intra-abdominal solid tumor.

The perforation was not seen at the time of the operation, but was revealed by the autopsy, at which it was found to be in the transverse colon. Fecal extravasation had been prevented by the firm glueing down, above and around it, of the omentum.

In the bristle case the condition was seen in the form of a tumor upon the external surface of the left upper quadrant of the abdomen, having the size of my closed fist and composed of chronic inflammatory tissue. The base was intimately united with the left rectus abdominalis muscle.

Symptoms and Diagnosis. One of the most interesting points connected with these cases for me personally, in so far as the diagnosis was concerned, was my failure to make a correct diagnosis in any of the cases; at least this was true with regard to the etiological factor in them. The reason for these errors was that no information was vouchsafed by any of the patients of their having swallowed a foreign body. In two of the cases I knew, it is true, that I had to deal with intra-abdominal abscesses, but their origin was entirely obscure. In two in which the small intestine was perforated near the ileo-cecal valve, the symptoms were absolutely typical of attacks

of subacute appendicitis, and I believed them to be such. In the perforation of the jejunum, the picture presented was that of an acute and severe peritonitis, and despite the absence of previous symptoms I was inclined to believe it to be a case of perforating ulcer of the duodenum. In the fish bone perforation with the large intra-abdominal abscess, there had been but very moderate intra-abdominal or constitutional symptoms and the gastro-intestinal function was but slightly disturbed. Here I knew that there was an intra-abdominal abscess, but whence it came I did not know. In the patient with the transverse colon perforation the symptoms had been mild for the first fortnight, but had increased in gravity during the ten or twelve days preceding his entrance to the hospital. He had lost strength rapidly during that period and was very critically ill when I first saw him. Constipation had been present for four days. His complexion was of grayish color. Tongue heavily coated. Pulse weak and rapid. Abdomen distended, and muscular rigidity was evident. Leucocytosis of 7000. Temperature, 99.8° F. The physical abdominal conditions found have already been described.

In the bristle case there was an entire absence of intra-abdominal and of constitutional conditions. The patient had noted merely the presence of a tumor in the upper left quadrant of the abdomen which had painlessly increased in size until it was as large as my closed fist. This tumor was closely attached at its base to the left rectus abdominalis muscle and had the feel and general history of a sarcoma of the abdominal wall. It was thus diagnosticated by two of my colleagues at the Massachusetts General Hospital, by one of them at the Boston City Hospital and by myself.

Its duration was two months.

Treatment. The treatment in three of the cases consisted in opening, cleansing the intra-abdominal abscesses and removing the foreign bodies. In the jejunal perforation the opening in the gut was closed by suture.

In the two cases simulating appendicitis, the foreign bodies were removed. In the one in which the toothpick had made a perforation of the gut the opening was closed with one suture. The appendicees were taken out as a matter of routine. The abdominal wounds were closed tight without drainage.

In the bristle case I made an incision into the tumor in order to remove a small bit to send to the pathologist for a rapid diagnosis, and by good chance exposed in so doing the tip of the bristle you have seen tonight. Enlarging the incision I traced it to and through the abdominal wall. It was removed, the mass of chronic inflammatory tissue was cut off at the base and the wound closed.

Remarks. It is impossible to determine the proportion of cases in which perforation by foreign bodies that have been swallowed occurs, relative to the whole number of those persons who

have taken them into the stomach and intestine. This, because the number of those through whose gastro-intestinal tract they pass without injury and whose cases, therefore, are not published, is doubtless far in excess of those whose cases have been reported. In the reported cases of foreign bodies ingested, perforation has occurred in about 8.0%.

Foreign bodies remain, as a rule, longer in the stomach than in the intestine, so too is the stomach more often the seat in which foreign bodies are found to be present than the intestine.

The longer the foreign body is, the more likely it is to be detained in the stomach. The shorter ones usually pass into the intestine.

The character and the number of foreign bodies that have been passed through the whole length of the gastro-intestinal tract without inflicting serious injury upon it, is extraordinary. Among them are recorded the following: Pocket knives, hairpins, safety pins (open and closed), nails of different sizes, bits of glass, table knives, spoons and forks, fish hooks, and a large variety of substances such as bones, bits of lead solder and of enamel from tin and other sorts of vegetable cans.

Per contra, far less formidable foreign bodies have caused perforations of the stomach or intestine some of which have resulted fatally.

One point worthy of being noted is: that perforation has taken place in the bowel in a few instances after the foreign body has passed through and out of the gastro-intestinal tract, seemingly without having inflicted any injury. In these cases the subsequent perforations have been produced as the result of an ulcerative process set up by the foreign body during its stay in the bowel, some point in which has thereby become weakened and finally given way.

One of the factors determining the detention of foreign bodies in the intestine and, in a certain number of cases, perforation, is the existence of narrowings, or constrictions in it. The more frequent causes of these are the results of tuberculous disease, syphilis, and kinks of the bowel.

The most frequent sites of perforation of the intestine are in or near the right iliac fossa. We have all had a greater or less number of cases in which foreign bodies have perforated the appendix, of course. In a considerable number perforations take place in the cecum and in the small intestine near the ileo-cecal valve. Another favorite site of lodgment and sometimes of perforation, is near the anus. In a few instances of this character fatal phlegmon around the rectum has been produced following perforation at this point. I do not know the relative number of perforations of the stomach as compared with those of the intestine, but it is my impression that they are fewer in the former and that the larger number of these have been made by knives and other sharp bodies that have been ingested.

Sometimes the foreign body has made its way through the intestine and into the vagina or bladder. One interesting example of the latter condition is reported by the English surgeon Mr. Reginald Harrison.

The patient came to the hospital in this instance because of a stone in the bladder. On doing a lithotomy operation Mr. Harrison withdrew a calculus of unusual shape. It was of long oval form. Its nucleus was found to be the stem of a pipe. The patient on being questioned declared that he had swallowed the mouthpiece of his pipe during a drunken sleep. He had experienced no trouble from it and did not associate his vesical symptoms with the incident. In this case the communicating opening between the bowel and the bladder had closed spontaneously. In other examples of this condition and of the cases in which the foreign body has been spontaneously discharged on the surface of the abdomen, fecal fistula has resulted and required operation in order to close it.

An interesting and important feature of the cases of perforation of the stomach or intestine by foreign bodies that have been swallowed, is that in a large number of them the area of the peritoneum immediately about the site of the perforation is already walled off by an adhesive process before the foreign body actually penetrates the wall of the intestine. It is because of this fact that the number of fatal results from perforations of this sort is so small. It may be estimated from a series of 82 cases collected by Wölfler in which but eight deaths occurred.

The course observed in the majority of cases is that which is seen in my own series; that is to say, the clinical picture is presented of a circumscribed peritonitis of varying degrees of intensity.

In a considerable number of the cases there is formed an intra-abdominal abscess, and a good many of these make their way to the surface of the abdomen and are spontaneously evacuated there. The foreign body is usually evacuated with the contents of the abscess. In some instances it is retained and an operation is required for its removal.

In many of the cases the opening of the perforation has closed spontaneously before the abscess arrives at the surface. In a smaller number it remains open and a fecal fistula forms, as has been said.

The time occupied by such abscesses in reaching the surface is sometimes very long; weeks, and even months, have been noted in some of the cases.

In a few examples the abscess has pointed at a spot remote from the site of the perforation. Wölfler mentions one case in which it was found over the trochanter of one of the femurs.

In a few instances the conditions that were seen in the case of the bristle perforation in my series, have been met with: that is to say, the formation of a solid tumor, external to the abdominal wall, and having the appearance of a

sarcoma. In these cases the foreign body has usually been of small caliber and the mass of chronic inflammatory tissue is produced by long continued irritation.

The length of time during which foreign bodies that have been swallowed remain in the gastro-intestinal tract varies greatly. The shortest time that I have found recorded in any case was five hours. The average time is from three to six days. Months may elapse before they are passed out, and in a few cases the body has remained without its presence being suspected throughout life.

The most interesting examples of the taking of foreign bodies into the gastro-intestinal tract are to be found in that class of talented persons who have elevated the art of swallowing all manner of objects to the dignity of a profession.

I may briefly refer to two examples of these people. My attention was directed to the first of them when passing the portals of a dime museum by seeing a placard which bore the following legend "The World's Wonder—The Great Australian Glass Eater." Beneath the placard stood a barrel filled with bits of glass of varied shapes and sizes, and upon the barrel were painted the words "His Diet."

I entered and watched this gentleman eat his noonday meal. It consisted in a goodly number of bits of glass. This he swallowed seemingly without discomfort. I was informed that he had been engaged in this nutritious occupation for no less than five years. He presented the appearance of excellent health.

In the stomach of the second person of this fraternity the presence of the following objects was revealed by a radiograph: Two watch chains, three door keys, eight horse-shoe nails, some bits of glass, a breastpin, six safety pins—two of them open, a pocket knife, and some other articles the nature of which I do not now remember. These represented the residue of this person's diet during the previous six months. He ultimately became afflicted with symptoms of dyspepsia and sought medical advice. A gastrotomy operation was done and the articles named above were restored to him, and after a short convalescence he resumed his former professional vocation.

Some of the professional "swallowers" have had a less fortunate fate, however. Wölfler reports two instances in which, the stomach having been perforated by knives that had been swallowed, death resulted as a consequence.

The two points which have especially interested me in connection with this subject have been: The difficulties that may be offered to making a correct diagnosis which is due to the absence of information of a foreign body having been swallowed, and, the seeming injustice displayed by the unequal distribution of the immunity to injury that is exhibited by certain persons who are privileged to swallow without harm almost anything they can take into their mouths; while others cannot swallow even so

innocent looking a body as the bristle that I have showed you tonight without having a perforation of the stomach or intestine result, and being forced to live in constant anticipation of impending death because of the presence of a tumor on the abdomen which was of a character such as to involve in an error of diagnosis four of Boston's distinguished surgeons, one of whom has just had the pleasure of addressing you.

VARIETIES OF THE GOLD SOL TEST (LANGE) IN SEVERAL LOCI OF THE CEREBROSPINAL FLUID SYSTEM: A STUDY OF TWENTY-EIGHT AUTOPSIED CASES.*

BY H. C. SOLOMON, BOSTON,

*Assistant in Neuropathology, Harvard Medical School;
Junior Assistant Physician, Psychopathic Department, Boston State Hospital;*

AND

E. S. WELLES, BOSTON,

Interne, Psychopathic Department, Boston State Hospital.

THE present communication offers evidence that the cerebrospinal fluid in different loci varies in its chemical composition. The method of examination used is the gold sol reaction of Lange. The test was performed on fluids obtained post mortem in a series of twenty-eight cases. The attempt was made to obtain fluids from the several cisternae and spaces, namely:—

1. Cerebral subarachnoid space.
2. Epicerebral space.
3. Lateral ventricles.
4. Third ventricle.
5. Cisterna at base of brain.
6. Spinal subarachnoid space.

Obviously it is quite difficult, if not impossible, to obtain a clear (bloodless) fluid on all occasions; consequently fluid was available from many less than the possible 168 loci. From fifty autopsies, clear fluid was obtained from at least one locus, in twenty-eight from two or more loci, and in several others no clear fluid was obtained.

The gold sol reaction is now being used extensively in clinical laboratories for the examination of cerebrospinal fluids. It is an application of the reaction of albuminous substances with colloidal gold. It has been shown and especially worked out by Zsigmondy¹ that albumins may be

* Being Contributions of the State Board of Insanity, Number 40, (1915.6). This communication was presented at a meeting of the Boston Society of Medical Sciences, January, 1915. This work was made possible through the courtesy of the Pathological Service of the Massachusetts State Board of Insanity, to whom our sincere thanks are given. (*Bibliographical Note.*—The previous contribution was Number 39 (1915.5), by H. C. Solomon and E. S. Welles, entitled, "On the Value of the Gold Sol Test (Lange) with Spinal Fluids Obtained Post Mortem," published in the BOSTON MEDICAL AND SURGICAL JOURNAL, Vol. CLXXII, No. 11, March 18, 1915.)

analyzed by their reaction with colloidal gold solutions. If to a colloidal gold solution one adds an electrolyte the gold is precipitated in the form of metallic gold. If, however, a proper albumin is added this precipitation (*Ausflockung*) does not occur. The different albumins offer this species of protection to the gold solution, depending on dilutions. They have been charted according to this characteristic, and different ones can thus be separated by the so-called "gold number." This is true of proto- and hetero-albumoses, while, on the other hand, deuto-albumoses react with the gold colloid as do electrolytes, and cause the precipitation of the gold. Spinal fluids from cases of certain inflammatory conditions of the central nervous system, such as the meningitides, tabes, paresis, etc., act in the manner of the deuto-albumoses and cause a change in the colloidal solution. Spinal fluids from cases in which there is no evidence of an inflammatory process often exhibit no effect, or only a slight one, with the gold sol test. There seems to be no doubt that it is the proteid element in the spinal fluid that causes the change, a proteid different from that normally present in the spinal fluid.

The technic and details of the test may be found in the original articles by Lange,² or in English by Sippy and Moody,³ Miller and Levy,⁴ or Kaplan.⁵ It will suffice at this time to state that the test is performed with ten dilutions of spinal fluid in 0.4% NaCl. solution, the dilutions ranging from 1/10, 1/20, 1/40, etc., to 1/5120, to each of which 5 c.c. of a preparation of gold colloid is added. The intensity of the reaction is read according to the amount of color change ensuing. The colloidal gold solution is cherry red in color, and the change in color due to partial precipitation, runs through red blue, blue red, blue, pale blue or lavender, to colorless, when all the gold has been precipitated. These changes are charted by numbers, the red unchanged fluid being designated by 0, the colorless solution by 5.

As stated above, the tests on which this paper is based were performed with cerebrospinal fluids obtained post mortem. One wonders at once if the results obtained with these post-mortem fluids are analogous to results obtained with spinal fluids obtained ante mortem. We discussed this question in another paper,⁶ and concluded that the evidence showed that: "The gold sol test has the same value in the examination of cerebrospinal fluid obtained post mortem from the lumbar region as ante mortem, and the results may be similarly interpreted for diagnostic purposes." Many of the cases discussed in that consideration are included in the present series.

The point to which we wish to call especial attention in this communication is that the reaction of the colloidal gold solution may vary in the fluids from the same case taken from different loci of the cerebrospinal fluid system.

Thus the fluid from the lumbar region may differ in its reaction with the gold sol, thereby proving a difference in the albumin content, from the fluid obtained from the third ventricle, which in turn may differ from the fluid of the lateral ventricles or subarachnoid space, and these fluids may each differ from one another. Such a difference is not invariable, for the reaction may be negative in several loci, and fluids from the different loci may give the same positive reaction.

There are 28 cases in which the fluid has been obtained and examined from more than one locus. In 24 of these 28 cases the reaction differed in fluids from the same case obtained from different loci; in 4 cases the results were identical. In two cases the reaction was identical in two loci, while differing in other loci; in five more the reaction in two loci was very similar but differed from that obtained in other loci of the same case.

Three cases (Nos. S. B. I. 1914. 58, 87, and 76) may be cited as striking illustrations. The spinal fluid obtained from the lumbar region in No. S. B. I. 1914. 58 gives the "paretic reaction," as did the *ante-mortem spinal fluid*, and general paresis is the diagnosis confirmed by post-mortem examination. The fluid from the third ventricle gives a strikingly different reaction.

Spinal fluid.....	5	5	5	5	5	5	5	5	4	3
Third ventricle.....	0	1	2	2	3	3	2	2	1	0

The spinal fluid from No. S. B. I. 1914. 87, another case of clinical general paresis, again gives the "paretic reaction," but the fluids from the base of the brain, subdural space and third ventricle each give different reactions, becoming less marked in that order.

Spinal.....	5	5	5	5	5	4	4	4	3	2
Base of brain.....	3	3	3	4	4	5	2	2	1	1
Subdural space.....	3	3	3	2	2	2	1	0	0	0
Third ventricle.....	0	0	0	1	1	0	0	0	0	0

That such a difference in reaction from the different loci is not characteristic in general paresis, or that the fluid in the third ventricle necessarily gives a slighter reaction than the spinal is proved by the following examples. No. S. B. I. 1915.1 gives the typical reaction with fluid obtained both from the base of the brain and subdural space.

Base of brain.....	5	5	5	5	5	5	5	5	5	4
Subdural space.....	5	5	5	5	5	5	5	5	5	4

No. S. B. I. 1914. 75 shows the "paretic reaction" with the spinal and subdural fluid and an almost identical reaction with the fluid from the third ventricle.

Spinal.....	5	5	5	5	5	5	3	0	0	0
Subdural.....	5	5	5	5	5	5	5	4	3	2
Third ventricle.....	3	5	5	5	5	5	3	2	0	0

No. S. B. I. 1914. 75 (not included in this series as fluid obtained but from one locus) shows that the fluid from the third ventricle may give

a reaction of the fullest intensity. This again is a case of general paresis.

Third ventricle..... 5 5 5 5 5 5 5 5 5 5

No. S. B. I. 1914.76, a hydrocephalic imbecile with cerebrospinal tuberculous meningitis, gives with the fluid from the lateral ventricles and base of the brain reactions which, while differing from each other, are such as have been described as being found in tuberculous meningitis. The spinal fluid gives a very different reaction.

Lateral ventricle..... 0 0 ± 2 2 2 1 0 0 0
Base of brain..... 0 0 0 0 0 1 2 2 1 0
Spinal..... 1 1 1 1 1 1 1 2 2 3

From a perusal of all the cases it is seen that in some instances the reaction is stronger in one locus, in other cases a different locus gives the greater reaction so that there is no definite rule to be observed, unless the rule that chemical differentiation is characteristic of many fluids.

These differences in reaction in different loci prove that there is a difference in the albumin content of the fluids obtained from the several loci. This difference is qualitative and not merely quantitative, for the reaction as here obtained does not depend so much on the quantity of albumin present as on its composition; thus the reaction in its intensity or the dilution in which it occurs does not depend on the amount of albumin precipitated by trichloroacetic acid or the amount of globulin precipitated by half saturation with ammonium sulphate, but evidently on the kind of albumin. Such differences of reaction with the fluids from the different loci are of great significance in the clinical application of the Lange test, for in this test the fluid is obtained by ordinary lumbar puncture, and expected to give us information concerning a pathological process at work in a locus often at a distance. But the reaction obtained in the spinal fluid may be very different from that to be obtained from fluid in the cortical region. Thus in general paresis the region of greatest interest is the cerebral cortex; but the fluid examined gives no necessarily true criterion of the condition of the fluid in the situation where the parietic process is at work. Since this is the case, there is reason to suspect that not every case of general paresis will give the same reaction in the spinal fluid. We believe there is sufficient clinical evidence to substantiate this.

Of still greater importance than the matter of the specificity of the Lange test for differential diagnosis is the bearing of the facts here presented on the question of the physiology of the cerebrospinal fluid system. Very little is definitely known as to the direction of flow of the fluid. There is a difference of opinion concerning the communication of fluid from one locus to another. It is stated in Quain's Anatomy that, "All the various subarachnoid spaces from a series of intercommunicating channels, and the fluid they contain is continuous with that of

the ventricular cavities by the foramen of Magendie and the foramina of Luschka." Plaut, Rehm and Schottmüller state: "The cerebrospinal fluid of the brain and spinal cord are in free communication with one another. It is to be accepted with great probability that the fluid in the ventricles communicates with the fluid of the subarachnoid space." Other investigators, as Cruveilhier, Reichert, Kölliker, deny the existence of the foramen of Magendie. McIntosh and Fildes, Head and Earnshaws have recently written: "It is doubtful to what extent the ventricular fluid contributes to its (the spinal fluid's) constitution, and we think that it is improbable that this fluid passes directly from the ventricles into the cerebrospinal fluid by way of the foramen of Magendie, even when this exists."

Mestrezat¹⁰ and Kaplan⁵ state that in certain cases of icterus where the spinal fluid was discolored yellow by bile pigment it was found at autopsy that the ventricular fluid was clear, showing in these cases that there was no free circulation from the fluid of the cord upward to the fluid of the ventricles.

Several authors have spoken of a difference in the composition of the fluid in different loci such as shown by our results. Thus Mott¹¹ quotes Sir T. Barlow and Dr. Lees: "Cerebrospinal fluid obtained from any point below the fourth ventricle cannot be a pure secretion; it must contain waste products resulting from cerebral metabolism, for into the subarachnoid space surrounding the brain open the lymphatic sheaths of all the cerebral arteries." In like manner Cushing states: "There are reasons for believing that there may be recognizable differences between the two fluids—ventricular and subarachnoid—under normal, as well as under experimental and therapeutic conditions, owing to the possible accretion to the ventricular fluid of waste substances during its passage through the subarachnoid perivascular and perineuronal spaces." And again: "Fluid secreted by the plexuses is not the same in composition as that contained in the cerebrospinal spaces, in view of the probable increment it must receive from these perivascular lymphatics." Cushing in the same article reports that Jacobson has shown that, "Comparative studies of the spinal and ventricular fluid show that there is a slightly higher percentage of sugar in the ventricular than in the subarachnoid fluid, whereas the reverse is true of the albumen content." And he further reports an instance where the Wassermann reaction in the blood serum and spinal fluid was negative, but positive in the ventricular fluid.

It is an unsolved question how much adhesions have to do with this difference in composition of the fluids from the different loci of the same case. Southard¹² showed that in syphilitic meningitis the adhesions might form compartments and thus cause to result a difference in

the cellular content above and below such adhesions. In the majority of the cases seen at autopsy in the hospitals for the insane there is some evidence of thickening of the meninges, and there might well be such adhesions.

Our work with the colloidal gold test demonstrates that the composition of the cerebrospinal fluid in the various cisternae and spaces of the cerebrospinal axis may differ, and that therefore in all probability there is not a free circulation or exchange of the fluid. We have further proved that the examination of the albumin content of cerebrospinal fluid obtained by lumbar puncture is not in all cases a true indication of the condition existing higher up. What is true of albumin is probably true of other substances, particularly the Wassermann reaction, as the Wassermann bodies are probably contained in the globulin.

A STUDY OF LEPROSY: WITH ESPECIAL REFERENCE TO THE PULSE AND TEMPERATURE.

By JAMES A. HONEIJ, M.D., BOSTON.

From Penikese Hospital and the Department of Bacteriology, Harvard University Medical School.

(Continued from page 584.)

CASE 7. S. G. Sex, male. Age, 70. Social state, married. Nationality, Russian Jew. Resident in United States, 15 years. Resident at Penikese, 5 years. Diagnosis of leprosy made 6 years ago. Type

of disease, mixed (?). Stage of disease, slowly active. Most common lesions, ulcers. Dispensary attendance, frequent. Symptoms most marked, pain, diarrhea, throat. One "toxic-febrile" attack. Activities of patient, none. Disposition, good, apprehensive. Prognosis, unfavorable. Remarks, mouth, throat, bowels and bladder are troublesome. Weak heart.

Several factors other than leprosy influence the chart of this patient. The patient is 70 years of age, has cardiac disease and fairly frequent attacks of diarrhea. He is also of a neurotic temperament. Rise of temperature in this case was rarely followed by any abnormal increase of

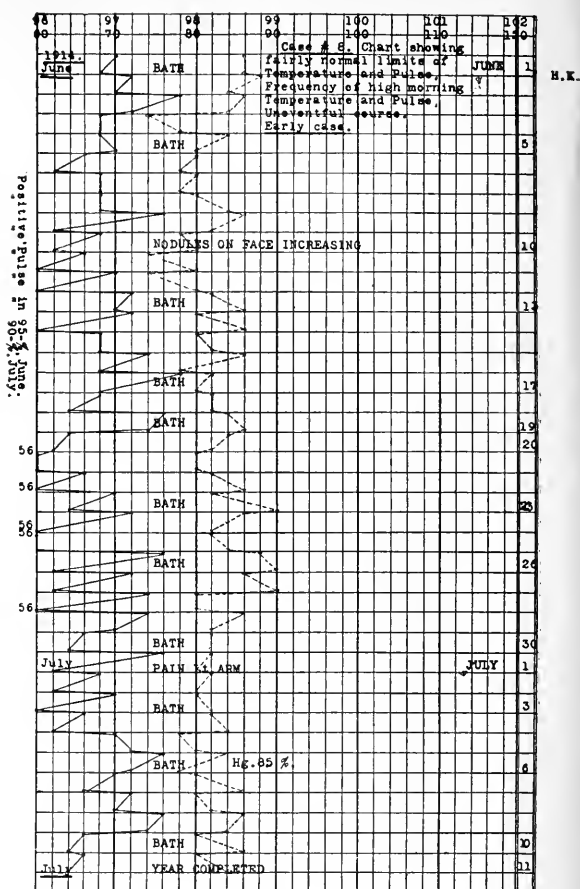

pulse rate. During the first four months under observation, marked rise of temperature, often of 4 degrees or more, occurred during attacks of diarrhea, accompanied by an increase in pulse rate of only 10 to 18 beats per minute. During the first few months the temperature was often elevated and very irregular. The two curves do not run parallel and the pulse curve is insignificant compared with that of the temperature. From November to April the temperature at evening was somewhat above normal and in the morning most frequently 97° and less. During this same period, however, the pulse irregularity with its frequent high exacerbations, is most striking. The pulse curve now exceeds that of the temperature; whereas, previous to November, the temperature curve was above that of the pulse. During the last four months, when both temperature and pulse curves were within fairly normal limits, the "morning pulse" increase was marked. For the first four months this appeared as much as 31% of the time, for the following four months 40+%, and for the last four months 62%. Comparing the last period with the first, we find that the disease has run a more even course, with fewer lesions, slight and short attacks of diarrhea, and with but slight disturbances. This agrees with the temperature and pulse curves and, still more important, with the "morning pulse" increase, which is especially noticeable during the last three months, being recorded 71+ % of the time. During the whole year the patient has had one "toxic-febrile" attack with chills. He has grown feeble and has lost some weight.

CASE 8. H. K. Sex, male. Age, 27. Social state, single. Nationality, Russian Jew. Resident in United States, 8 years. Resident at Penikese, 1 year. Diagnosis of leprosy made 1 year ago. Type of disease, tubercular. Stage of disease, early. Condition of disease, slowly active. Most common lesions, bullae, ulcers, small tubercles. Dispensary attendance, infrequent. No "toxic-febrile" attacks. Activities of patient, light housework, little gardening and fishing. Disposition, good. Prognosis, favorable. Remarks, left eye troublesome, throat occasionally.

This is an early case and has been under observation for less than a year. The temperature and pulse have been within fairly normal limits for leprosy and have shown occasional slight irregularities. The disease so far has run an uneventful course. The chart shows the typical "morning pulse," which is also at intervals subnormal in the evening. An interesting point is the relative frequency of the higher morning temperature which occurs 30% of the time, and also that of the "morning pulse," which is present during the whole nine months, 80%. The patient has gained in weight.

CASE 9. M. M. Sex, female. Age, 52. Social state, married. Nationality, Portuguese. Resident in United States, 10 years. Resident at Penikese, 5 years. Diagnosis of leprosy made 5+ years ago.

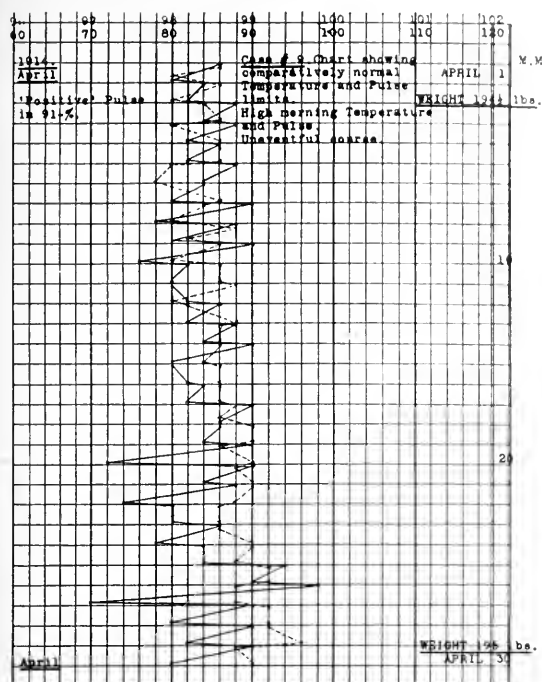

CHART No. 8.

Type of disease, anesthetic. Stage of disease, first, latent. Condition of disease, latent(?). Most common lesions, ulcers and blebs due to burns. Dispensary attendance, seldom. Symptoms most marked, none. One slight "toxic-febrile" attack. Activities of patient, cooking, light housework, walking. Disposition, excitable, irritable. Prognosis, favorable. Remarks, patient in excellent physical condition.

In this case the temperature and pulse remained within comparatively normal limits. With the exception of one chill during the year, which was accompanied by an elevation of temperature and pulse of 102° and 116, the patient has presented no acute symptoms or active lesions peculiar to leprosy. The pulse exacerbations were in all cases due to an excitable temperament. The chart for the year shows no differences from month to month. The temperature ranges between 98° and 99°, infrequently more than 99°. The pulse readings average between 80 and 90 for the twelve months. The temperature fall at night occurs for at least one-fourth the whole period and the pulse at least three-fourths of the time. A comparison between this case and Cases 7 and 4 is interesting. The patient has lost weight slightly; but, being extremely heavy, the loss in weight is considered a normal fluctuation. The patient is about to be discharged.

CHART No. 9.

CASE 10. J. N. Sex, male. Age, 30. Social state, single. Nationality, English. Resident in United States, 12 years. Resident at Penikese, 7 years. Diagnosis of leprosy made 10 years ago. Type of disease, tubercular. Stage of disease, advanced. Condition of disease, rapidly progressive. Most common lesions, ulcers, pustules, bullae, swollen glands. Dispensary attendance, frequent. Symptoms most marked, chills, pain, throat. Several "toxic-febrile" attacks. Activities of patient, none. Disposition, depressed, dissatisfied. Prognosis, unfavorable. Remarks, patient had all lesions and symptoms of leprosy. Died August, 1913.

This patient was under observation only one month when he succumbed to complications occurring in the course of the disease. The case is of interest because the chart shows the "morning pulse" on the greater number of days, also a marked difference in morning and evening rate. The pulse rate averaged between 90 and 100, and the temperature, which was more often lower in the evening than in the morning, was more frequently 97° than 98° or more. The temperature and pulse for the three days previous to death averaged as follows: temperature 95.1°, pulse rate 70; lowest temperature 94.2°, pulse rate 60.

CASE 11. L. P. Sex, female. Age, 35. Social state, single. Nationality, Lettish. Resident in United States, 16 years. Resident at Penikese, 7 years. Diagnosis of leprosy made 7+ years ago. Type of disease, tubercular. Stage of disease, fairly active, progressive. Most common lesions, bullae, ulcers, swelling of glands, etc., marked induration, nodules. Dispensary attendance, frequent. Symptoms most marked, pain, headache, swelling, chills. One severe, one slight "toxic-febrile" attack. Activities of patient, very active in gardening, wash-

ing, housework, cooking. Disposition, depressed, morbid. Prognosis, unfavorable. Remarks, typical tubercular "leontic" case. Throat troublesome at times.

In this case a greater fluctuation of pulse was seen than in the temperature. The variation of the temperature occurred in periods rather than daily, whereas the pulse showed a greater daily variation. From July to the first half of December and during the "toxic-febrile" attack, the pulse bore a fair relationship to the temperature, although the pulse tended to predominate. This became more evident from January to May, distinctly more so from May to July. The average pulse rate for the last three months was at least 10 beats higher, although the irregularity was not so noticeable. During the whole twelve months the patient had one severe "toxic-febrile" attack, accompanied by great swelling of arm and glands, pain, fever and despondency; and a second slight attack four months later. The whole chart is typical and bears out the opinion that progress of the disease can be studied in most, if not in all, the cases by this means. The most striking points are the gradual predominancy of the pulse, the increase in rate, the high percentage of "morning pulse" rises which occur during 70% of the whole period and 75+% for the last four months, the typical reaction during a "toxic-febrile" attack or after severe exertions, and the fall of temperature in the evening, which is found one-fifth of the time. The patient is strong and active and has gained in weight, although a considerable loss of weight is recorded after attacks.

CASE 12. F. P. Sex, male. Age, 47. Social state, married. Nationality, Portuguese. Resident in United States, 23 years. Resident at Penikese, 9 years. Diagnosis of leprosy made 10+ years ago. Type of disease, tubercular. Stage of disease, last.

CHART No. 11.

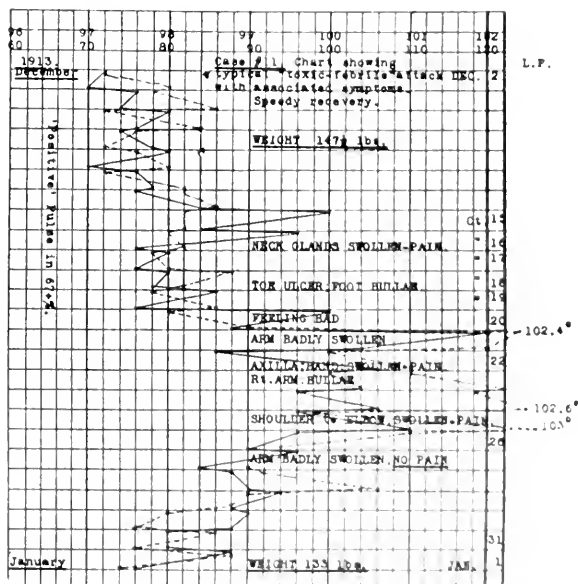

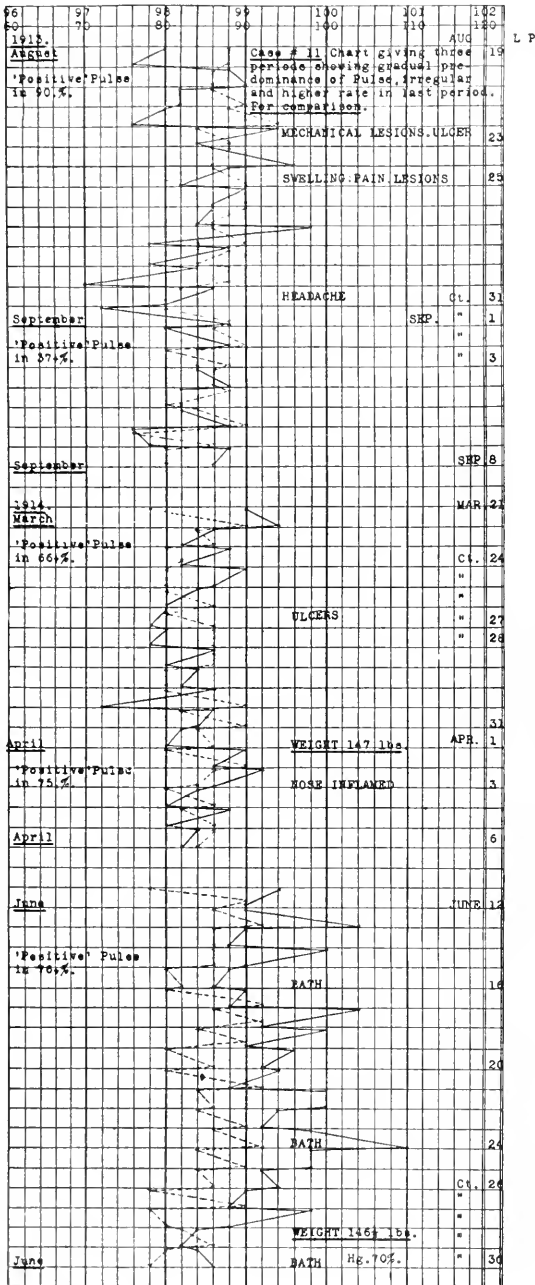

CHART No. 11 (continued).

advanced. Condition of disease, active. Most common lesions, ulcers, swollen glands, etc. Dispensary attendance, constant. Symptoms most marked, chills, pain, swellings, throat, diarrhea. One severe, two slight "toxic-febrile" attacks. Activities of patient, none. Disposition, good. Prognosis, bad. Remarks, patient is in final stages of the disease, mutilation severe.

This patient is in the most advanced stage of the disease. Lesions are numerous and his reactions are severe. Very slight disturbances result in an elevation of temperature and an increase in pulse rate (see chart). This rise of temperature and pulse curve was partly the re-

sult of shock, caused by a fall from a chair—the patient being blind. The average temperature was high for the first four months; markedly decreased during the next four months and again increased in the last period. During the last eight months the pulse has been more predominant, showing frequent elevations without similar increase in temperature. The "morning pulse" is fairly typical but is somewhat obscured by the constant reactions. The interrupted course of such an advanced case cannot be expected to reveal the same high percentage of this phenomenon as a chronic case with a regular temperature and pulse. The average number of days in which this "morning pulse" occurred during the whole period was 66+, and during the last four months 80%, when the course of the disease was more regular and presented practically no reactions. The patient is markedly anemic, hemoglobin index rarely exceeding 40%. The patient lost considerable weight during the year.

CASE 13. W. Q. Sex, male. Age, 38. Social state, single. Nationality, Chinese. Resident in United States, 14 years. Resident at Penikese, 1 year. Diagnosis of leprosy made 2+ years ago. Type of disease, macular, tubercular. Stage of disease, early. Condition of disease, questionably active. Most common lesions, pustules, enlarged glands. Dispensary attendance, fairly regular. Symptom most marked, pain. No "toxic-febrile" attacks. Activities of patient, light housework, little gardening and fishing. Disposition, good, apprehensive. Prognosis, favorable. Remarks, patient has improved considerably.

No chart among these cases shows better the improvement of the patient. During the first

CHART No. 12.

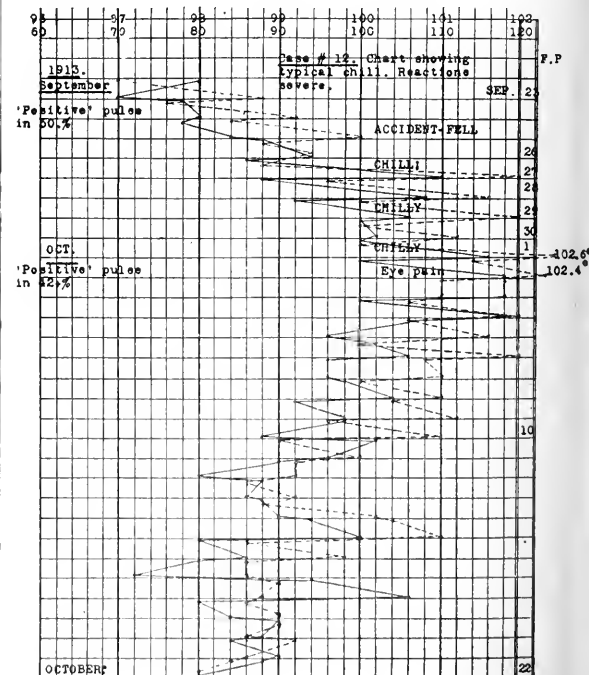

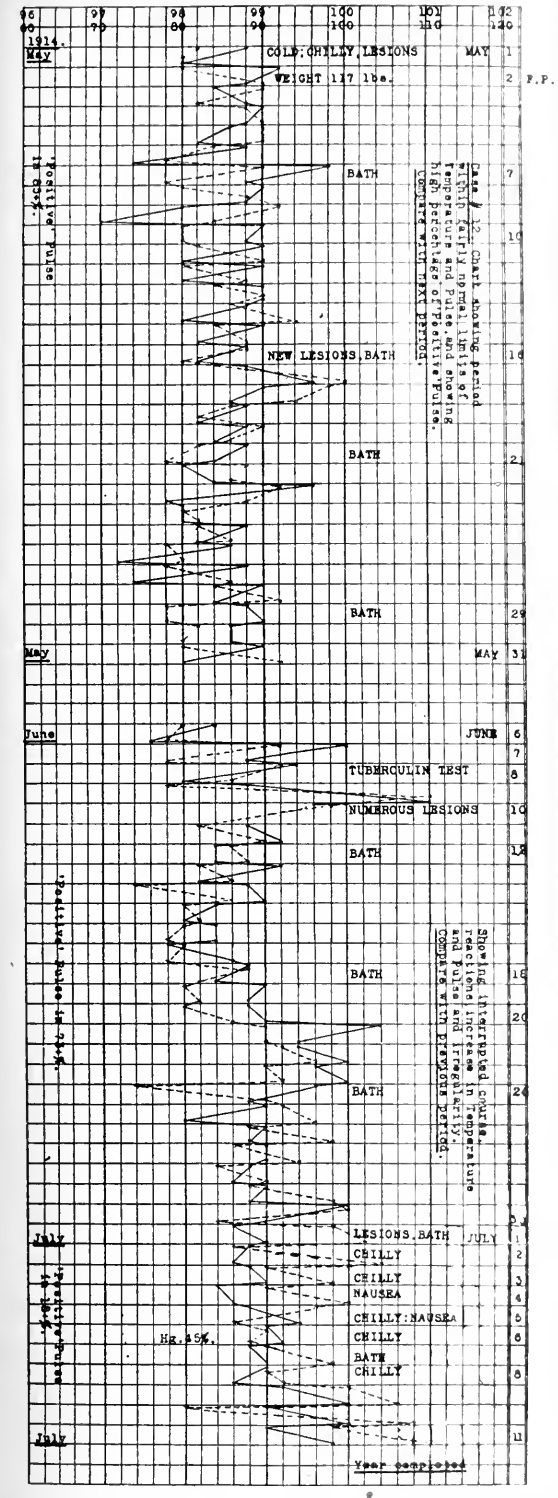

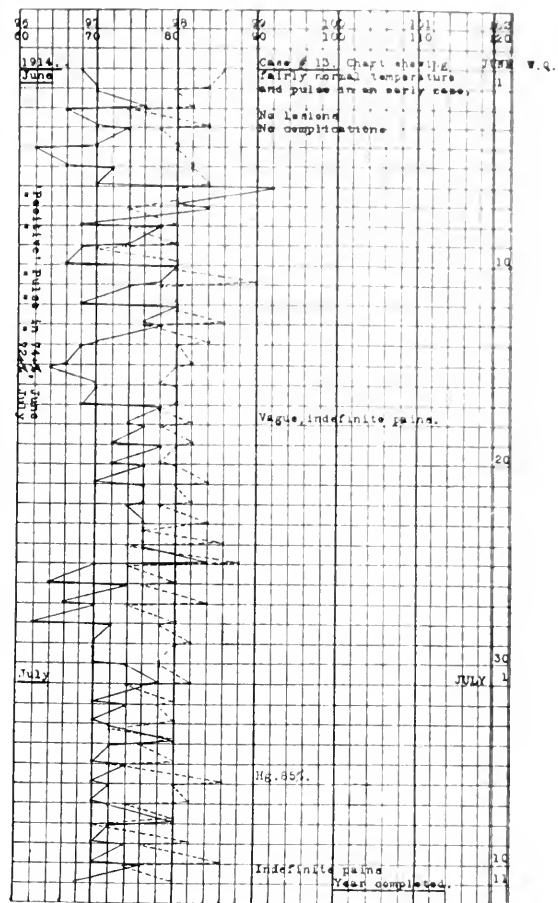

CHART No. 12 (continued).

two months the average daily temperature and pulse were highest and the daily remissions most marked; the last four months the temperature and pulse were nearly normal. The latter bore a more normal relation to the temperature. The patient has had no acute exacerbations and but slight reactions. The first five months showed

CHART No. 13.

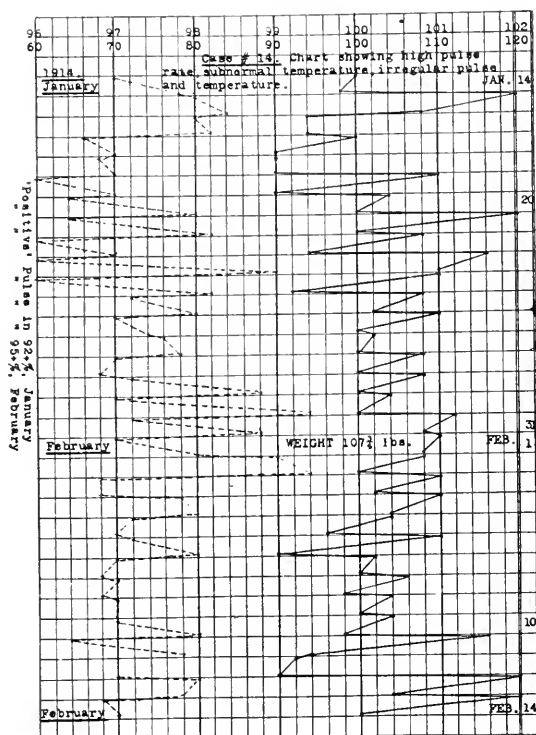

the lowest percentage of "morning pulse" rises, an average of 38%; the last eight months an average of 63+%. There is an evening fall in temperature in less than 1% of the whole time. During the whole period the temperature has never exceeded 100°, and reached this figure only three times. The pulse rate in only five instances exceeded 100 and exceeded 90 only eight times during the last five months. The case is interesting because the chart clearly demonstrates the improvement of the patient. The patient has not lost in weight.

CASE 14. A. T. Sex, male. Age, 22. Social state, single. Nationality, English. Resident in United States, 12 years. Resident at Penikese, 5 years. Diagnosis of leprosy made 6 years ago. Type of disease, tubercular(?), mixed. Stage of disease, advanced. Condition of disease, progressive, active. Most common lesions, ulcers, swellings, bullae, marked induration. Dispensary attendance, regular. Symptoms most marked, pain, swelling, fatigue. No "toxic-febrile" attacks. Activities of patient, indoor activities, amusements. Disposition, good, nervous. Prognosis, unfavorable. Remarks, patient has failed rapidly. Throat, nervous. Weak heart.

At first sight the chart demonstrates three points: a pulse rate out of all proportion to the temperature; a low, if not subnormal tempera-

CHART No. 14.

ture; and a daily, as well as a periodical, irregularity both in the temperature and pulse. Three main factors are responsible, namely, leprosy in an advanced stage, a cardiac lesion and a highly nervous temperament. The contrast is most marked when compared with Case 13. A comparison with Case 7, which is also a cardiac case, shows that that lesion is not alone responsible. That nervous influences alone are not of sufficient importance to produce such a condition of the pulse is best proved by a comparison with Case 9. This case has run a chronic course with no marked exacerbations or serious disturbances and should show a high percentage of the "morning pulse" during the whole course. This phenomenon occurred three-fourths of the whole time. The case is, therefore, typical and bears out the suggestions which this paper presumes to present. A study of all the charts will indicate more precisely the value of this case. Patient has not lost weight, although there has been considerable fluctuation from month to month.

In leprosy the lesions are due to the presence of bacilli-laden endothelial leucocytes in the vessel wall, which may in consequence be considerably thickened. Vessels in time may show much thickening of the walls and narrowing of the lumen (Mallory, Dohi, Marchoux). Jadassohn states that the changes begin in the vessels with infiltration of the walls. Authorities agree that degeneration of the nerves occurs (Sorel), motor paralysis, loss of sensation and hyperesthesia are frequent, while headache, neuralgia, "rheumatic" pains, neurasthenia, all indications of nerve involvement are common. The presence

of erythema, macular areas, local swellings, etc. (Darrier) are all evidence of the existence of vasomotor and peripheral circulation disturbances. The skin is infiltrated and shows in almost every case areas of induration. Atrophy of highly differentiated cells results, smooth and striated muscle cells disappear and connective tissue takes its place (Mallory).

Jadassohn believes that apart from mechanical disturbances, which the bacillus of leprosy causes, the endotoxin or toxin effect plays an important part. This he concludes logical, as the circulation is through organs that are heavily infected (Sugai, Bayon). The bacilli are in the blood stream (Rabinowitsch, Crow, Stephan) and probably more abundant during febrile attacks. It seems a matter of little doubt that this must have some effect on the heart and circulatory system.

The sudden and sometimes continued rise in temperature and pulse rate after exercise, as seen in leprosy, could be accounted for by the elimination of toxins into the blood streams as in tuberculosis (Paterson). It is known that the temperature of the blood exerts a powerful influence on the heart. It is also accepted that changes in composition or properties of the blood affect the pulse rate. Now if we consider the pathology of the circulatory system in leprosy, with the presence of bacilli in such enormous quantities in all lesions—greater probably than in any other disease (Bayon)—and are aware that the bacilli are found in the blood stream (Rabinowitsch, Stephan, Crow, Honeij) it is logical to believe that the bacilli of leprosy and their toxins are the cause of the symptoms occurring in the course of the disease. This is believed true of smallpox and pneumonia, specific marasmus (Kaufman) and other infectious diseases (McCrae).

The "toxic-febrile" attacks of leprosy with chills and other symptoms so characteristic of an infection, are undoubtedly results of the action of pathogenic bacteria in the skin lesions (streptococci, staphylococci). The cause of death in leprosy is due in the majority of cases to secondary infections. Therefore, it can be concluded that the whole train of phenomena of fever, nervous disturbances and chills denotes the action of toxin. In articles on lobar pneumonia (Musser and Norris) these statements appear: "The chill corresponds to time at which large doses of toxin are absorbed into the system" and that "rigor represents the period at which general systemic infection takes place."

In presenting a paper of this nature along original lines and in a disease so complex as leprosy, there are many difficulties to be overcome and in the discussion much is included that may give rise to valuable criticism. In leprosy there has been a conspicuous lack of clinical data, investigators apparently accepting it for granted that the disease presented no "symptom complex" different from other chronic diseases.

of temperature and the recovery by lysis gave a regular rise and fall, similar in some respects to Case 4, but more closely related to Case 5. In the latter the chart shows elevation of pulse and temperature during an attack with crisis and delayed recovery. In this case the pulse did not predominate, as it did in Case 5. The daily variations in temperature were greater for the whole period, but they showed an improvement for the last four months. The reactions during this last period were less severe and temperature and pulse were more nearly parallel and within usual limits. For the first two-thirds of the year the patient showed a condition suggesting general toxemia. There were no distinct chills with crises and no immediate reactions of temperature and pulse. The average number of days in which the "morning pulse" occurred was little over one-half the whole time and for the last four months it was approximately 62% of the time. During the latter period it was more regular and not influenced by secondary infections or serious disturbances. Throughout the twelve months the evening temperature was higher than that of the morning, except in one-half of one per cent. of the time. The average temperature and pulse for three periods of four months each was: T. 98° to 99°, P. 70 to 80; T. 98+° to 99+°, P. 70— to 80—; and T. 97° to 98°, P. 70 to 80. The patient is in an advanced stage of the disease, but has apparently lost no ground since March. There has been considerable loss of weight.

DIFFERENTIAL DIAGNOSIS AS REGARDS CHILLS, TEMPERATURE AND PULSE.

Charts Nos. 11 and 12 present two distinct periods of rise of temperature and pulse. Both cases showed symptoms and associated lesions, which I have termed "toxic-febrile" attacks. These attacks, when typical and severe, usually reach a climax upon the fifth to the tenth or twelfth day after onset. The curve assumes the picture of a "step ladder" until the temperature reaches 103° and pulse rate 120 or more. The descent to normal occurs in the same manner, although recovery is interrupted by frequent secondary exacerbations of periods varying between eight days and three weeks. Chills lasting from 15 to 60 minutes occur without regularity, preceding or during the climax of these attacks. During the period of observation no chills occurred that were not preceded by lesions, usually situated on the arms, hands, legs or feet. These were accompanied by extensive swelling, great tenderness and severe pain. The course of the lesions and accompanying symptoms is exceedingly rapid. The face is often flushed. Headache, nausea, apprehension and other nervous symptoms are usually present, followed by malaise and marked prostration. Pain and swelling later become localized and presently pus is located. These areas of infection, unless opened with evacuation of pus, form

ulcers of varying size and depth. The sooner the swelling is localized and opened, the sooner do the symptoms subside. In the year previous to this study, lesions and chills were exceedingly common. Since treatment has been instituted, lesions have been fewer and chills very infrequent. A study of these charts gives fairly conclusive proof that "toxic-febrile" attacks are associated wholly with secondary infecting bacteria. During this period of infection the characteristic appearance of the pulse disappears and the morning increase in pulse or temperature seldom occurs. A typical septic fever is seen in Case 5. This patient first presented severe lesions in both legs and feet. Later numerous pustules occurred over both thighs, buttocks, arms, hands and face, which continued for the better part of a month. There was no question whatsoever as to the part streptococci and staphylococci played here. This case is to be compared with Nos. 11 and 12, where the course is short, less severe, and in which a climax occurs with uninterrupted recovery. Sweating occurs infrequently and irregularly.

In *tuberculosis* chills occur early in the disease, before the rise of temperature, and not infrequently follow sweating.

The following charts, 16 and 17, show the typical temperature and pulse curves of tuberculosis (From the Boston Consumptives Hospital at Mattapan and selected by Dr. E. A. Locke, as being typical cases). The temperature and pulse show a regular rise and fall, with the usual rise at night. In the first case the prevailing average of temperature is 99+°, and in the second 100°. In tuberculosis, fever is not coincident with the rise of pulse rate. It is also believed that an increase in pulse rate of ten degrees and more for each degree of temperature is due to cardiac weakness. In these cases there is a constant difference between morning and evening temperature, and a reversal of high evening temperature in only two instances.

The pulse averages here between 80 and 90, except during high fever, when it is between 100 and 110. For a period of over four months the "morning pulse" is present 15+% of the time in the first case, and 12+% in the second. During the whole course the temperature, not the pulse, predominates. Sweating occurs during the course of the disease.

Chills occur in *malaria* before a rise of temperature. Within three hours a direct rise of temperature takes place from normal to 103° and 104° or more, immediately followed by a drop to normal. The rise of temperature occurs at regular intervals in all simple forms of malaria; pulse is rapid. The pulse, associated with an elevation of temperature in malaria, is always rapid. Sweating follows the attack. These symptoms present no similarity to leprosy.

In *lobar pneumonia* chills occur with the onset of the infection. A rise of temperature follows. The "morning pulse," which occurs in a small proportion of the time, usually shows a

CHART #16. Typical case of Active Tuberculosis.

For comparison with Leprosy cases.

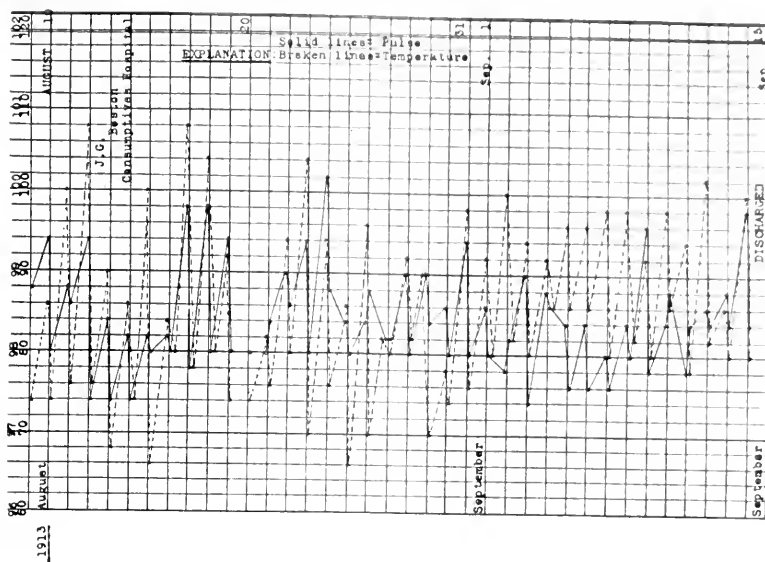

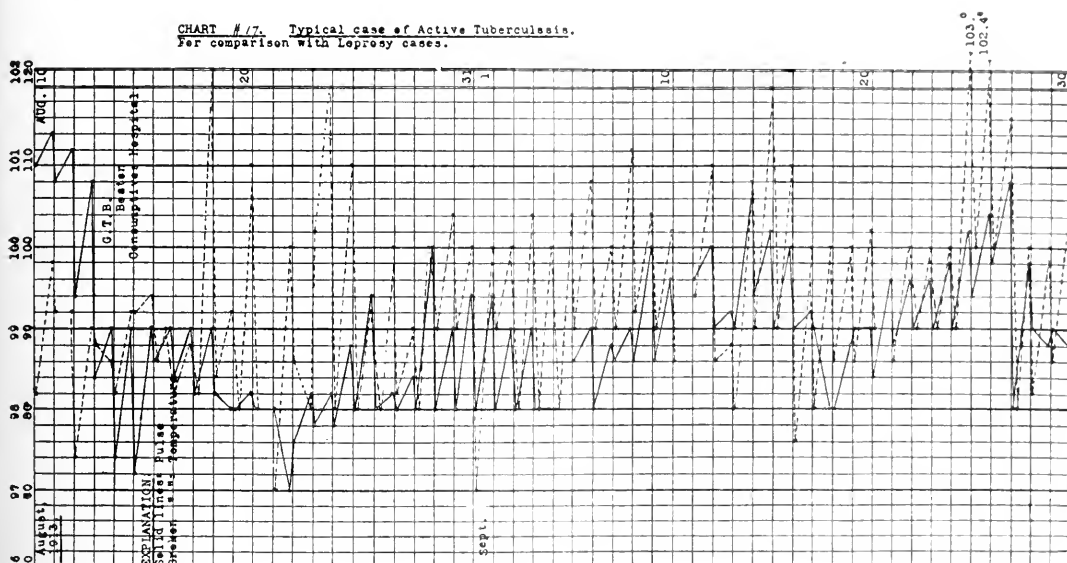

CHART #17. Typical case of Active Tuberculosis.

For comparison with Leprosy cases.

difference in rate of only three or four beats. This is nothing to compare with leprosy.

Erysipelas is ushered in with chilliness or distinct rigor, vomiting and rapid rise of temperature to 104° and 105° . The maximum is reached on the third day. After a few days of continued fever the temperature curve becomes irregular. Marked evening remissions, merging into a remittant or even an intermittent type, may occur. The disease terminates by crisis; or, after a longer febrile period, by lysis. In the latter instance the fever is prolonged and irregular. In no way is there a marked similarity to leprosy.

In *smallpox* chills mark the onset. Temperature rises rapidly to 104° and remains there with slight morning remission for about three days. In severe cases the decline is gradual.

Pulse and respiration are increased in proportion to the temperature.

In *glanders* and in septic infections chills occur. Only in this respect is there any similarity to leprosy.

A study of the records of cases at the Boston hospitals shows that in almost all cases other than leprosy, the "morning pulse" phenomenon, when present, was not constant. In none did it occur 50% of the time. In two cases of endocarditis and in one of myocarditis, in two cases of myxedema and in two of acute articular rheumatism, the largest proportion was found. In the following cases it appeared in a fair proportion: chronic nephritis with cardiac involvement, pneumonia, syphilis, psoriasis, eczema. In almost all cases where the "morning pulse" phenomenon occurred, the morning increase was

less than ten beats, generally only three and four beats. In conclusion, the following differential points between leprosy and other infectious processes are to be noted: the "morning pulse" phenomenon, which is found most commonly in cases of cardiac disease, does not occur consistently in any one disease and in less than 50% of the time in any one case. It occurs irrespective of height of temperature, even during a crisis. The difference in rate between morning and evening, when present, is usually only three or four beats. Finally, the pulse in almost all cases is correlated and consistent with the temperature.

(To be continued.)

Reports of Societies.

BOSTON DISPENSARY.

THE 118th annual meeting of the Boston Dispensary was held on the evening of January 21, 1915, at the Hotel Tulleries; Mr. Edward R. Warren, president of the institution, presiding.

Dr. S. S. Goldwater, Commissioner of Health, of New York City, well known for many years as superintendent of Mt. Sinai Hospital, was the principal speaker. His address is printed in full in this issue of the JOURNAL.* Dr. Allen J. McLaughlin, Commissioner of Health of Massachusetts, and Dr. Edward H. Bradford, Dean of the Harvard Medical School, delivered brief addresses in discussion of the same subject.

Dr. McLaughlin referred to the necessity of bringing public health work to the mass of the people by continuous and persistent effort. "The important service which dispensaries can render in this regard needs to be made effective," said Dr. McLaughlin, "by ample provision of the service of visiting nurses and social workers. The development of this visiting and social service in the homes, as the advance guard of medical relief, is one of the most valuable contributions which any medical institution can make, and should be vigorously pushed in the interest of public health."

Dr. Bradford, in opening his remarks, referred to the fact that he had become connected with the medical staff of the Boston Dispensary forty years ago and that since then, though retired from service in the institution, he had followed its development with much interest. He spoke of the important function of dispensaries in educating medical students, pointing out that the type of medical teaching had greatly changed from the days when instruction was largely didactic to the present time, when dispensary clinics are utilized for giving medical students every opportunity for intimate observation of the sick and of the actual work of diagnosis and treatment. "One of the most valuable services to be rendered by dispensaries today," said Dr. Bradford, "is that of educating the community in the knowledge of hygiene. As many dispensaries reach thousands of patients annually, the power they may exert as educational agents may well be of great importance."

* See JOURNAL, page 613.

PROCEEDINGS OF THE BOSTON SURGICAL SOCIETY.

STATED MEETING HELD AT THE BOSTON MEDICAL LIBRARY, MARCH 1, 1915.

The President, Dr. GEORGE H. MONKS, in the Chair.

PERFORATION OF THE STOMACH AND INTESTINE BY FOREIGN BODIES THAT HAVE BEEN SWALLOWED.

Dr. FRANCIS S. WATSON read a paper with the above title. (See JOURNAL, page 622.)

Dr. DANIEL F. JONES: That Dr. Watson has had a most unusual experience, is shown by the statistics of the Massachusetts General Hospital. The catalog shows that between 1896 and 1914, there were twenty-six cases admitted to the hospital because of foreign bodies in the stomach or intestines. All of these cases except three were discharged well, without operation, while three were operated upon. One because of a hatpin which had perforated the stomach and stuck into the liver; the second was a hair pin which had perforated the duodenum, and the third was an open safety pin which had lodged at the cardia. The first two cases were operated upon successfully; the third case, a child of eleven months, died before the operation was complete, probably of enlarged thymus.

It was in 1886 that Dr. Richardson reported his case of removal of false teeth from the esophagus through a gastrotomy. At the same time he collected thirty-two cases of gastrotomy for foreign bodies, which had perforated the stomach. In fourteen of these, the stomach was uninjured; three died. In eleven cases, the stomach was injured and adherent; one died. In eight cases, the condition was not indicated; one died.

Friedenwald and Rosenthal, *New York Medical Journal*, July 18, 1903, were able to collect but ninety cases (including the thirty-two collected by Dr. M. H. Richardson) of gastrotomy for foreign bodies, which had perforated the stomach. Of these cases, six had caused an abscess of the anterior abdominal wall, and three, perforation with death.

Of nineteen cases operated upon in pre-antiseptic days, 21% died. Of seventy-one cases operated upon since then, 8% died after operation. They conclude that: "Operation should be insisted upon immediately after the foreign body is swallowed," which seems hardly consistent with the facts.

In looking over the *Index Medicus*, for the year 1913, I was able to find reports of but three cases of perforation of the intestine, two of the duodenum, one of the ascending colon.

While Dr. Watson's paper does not go into the subject of foreign bodies in the appendix, I cannot refrain from referring to the fact that a number of years ago, when looking up the cases of abscess of the liver, in which the appendix was the primary focus, I found that of one hundred cases, a pin was found in the appendix, in fourteen.

To me the most interesting group of cases due to perforation of the intestine by a foreign body is the group of actinomycosis of the abdominal wall.

Among eight cases of actinomycosis of the abdominal wall, at the Massachusetts General Hospital between 1896 and 1914, a fish bone was found in the mass, in three. While this is not a large number of cases to base an opinion upon, I believe that if a sufficiently careful search were made, a

foreign body would be found in every case, to have caused the infection, rather than infection from a simple ulceration.

DR. C. L. SCUDDER: I should like to report briefly one case of

ACTINOMYCOSIS OF THE ABDOMINAL WALL.

In May, 1905, a Swedish woman, 49 years old, entered my service at the Massachusetts General Hospital. She complained of abdominal pain and lumps. An abdominal tumor was felt in the region of the umbilicus. It was thought to be a tumor of the abdominal wall. The skin over the tumor was red and presented a small sinus. The tumor was about the size of a small orange, non-fluctuant and projected posteriorly into the peritoneal cavity. Actinomycosis was considered as a possible diagnosis but no actinomycetes were found in the discharging pus.

At operation the mass was removed including the whole thickness of the abdominal wall. The tumor was adherent to the transverse colon from which it was separated.

The tumor itself is of interest. It consisted of much fibrous tissue surrounding a fish bone two inches in length which lay at the bottom of the removed mass. The patient admitted that 12 years previously she had swallowed a good-sized fish bone. Evidently this fish bone which had been swallowed had perforated the transverse colon and the abdominal wall and was being extruded through the fistulous opening. Of very great interest is the fact that Dr. James H. Wright discovered in the pus in the bottom of this sinus actinomycetes. In other words, the fish bone which had traveled through the transverse colon had made an atrium for the entrance of the actinomycetes from the intestinal tract into the soft tissues of the abdominal wall.

In a study of actinomycosis Dr. Wright has called attention to the fact that probably actinomycetes bovis is a normal inhabitant of the gastro-intestinal tract of both man and animals. He also called attention to the fact, which this case so beautifully illustrates, that the part played by the foreign body is not that of a carrier of actinomycosis, but that the foreign body (the fish bone in this case) by its irritative and traumatic effect furnishes a nidus in the tissues and enters with the secretions of the gastro-intestinal tract producing the lesion called actinomycosis.

This case then is of interest and importance in connection with the paper of Dr. Watson, for it is a case of a foreign body swallowed which subsequently perforated the intestinal tract.

This patient was seen by me in 1914, nine years following operation, and, so far as the abdominal wall is concerned, is well. There is no sign of actinomycosis either in the abdominal wall or elsewhere.

DR. C. A. PORTER: I have had three cases of foreign bodies in actinomycosis of the sub-maxillary region, one a beetle's wing, one a toothpick, and one a piece of bone. This fact shows that there were actinomycetes in the mouth. Infection in all cases came from the buccal cavity. This is Dr. Wright's idea.

DR. DAVID CHEEVER: I have had two cases of perforation of the bowel of a type, which the reader has not mentioned, and very likely did not intend to include in his remarks. I refer to perforation occurring in a hernia,—not necessarily strangulated, but where the solid body finds it impossible to pass by the sharp angulation of the gut.

The first case was that of a Polish patient, admitted last summer to the Brigham Hospital, with the diagnosis of strangulated inguinal hernia. The history covered a period of five days. At operation, there was found an incarcerated, but not strangulated, inguinal hernia. The sac contained a large amount of pus, which communicated freely with the abdominal cavity, where there existed a general peritonitis. The source of the infection was due to the perforation of the bowel by a long slender bone,—probably the rib of a small mammal, which undoubtedly could have easily passed through the intestinal tract, had it not been for the sharp kink occurring in the hernial sac. Enterostomy and drainage of the peritoneum failed to save the patient, whose death two days after admission was due to the general peritonitis.

The second case was noted within the past week in the anatomical laboratory at the Harvard Medical School. Upon opening the abdomen, the clinical picture of intestinal obstruction was presented, almost the entire small intestine being markedly distended except for a small portion, which was totally collapsed. On further examination, a well-marked cavity in the wall of the pelvis was demonstrated, passing through the right obturator foramen into the adductor region of the thigh. The cavity was about 3 or 4 cm. in diameter and depth and a distended and collapsed coil of bowel was seen entering and emerging from it. Withdrawal of the gut was at first impossible until it was found that a small sharp bone, probably a splinter from a chicken bone, was impacted in the hernial cavity and had fixed a coil of bowel within it, at the same time perforating its wall and starting a local peritonitis. Here again, the bone would undoubtedly have easily passed through the intestine, had it not been for the sharp angulation at the above-mentioned point.

DR. MONKS: Dr. Watson has referred to his seeing professional glass-eaters in dime-museums while they were engaged in their business of eating glass. I remember that on one occasion a glass-eater in one of these museums gave me a special exhibition of his glass-eating abilities. Taking in his hand an ordinary claret glass he bit the edge off completely round the glass, and then chewed what he had bitten off. Finally, he pushed out his tongue, showing the broken glass fragments upon it. I noticed also, by the way, a drop of blood on the tongue close to these fragments. The man, after he had apparently swallowed the fragments, made no objection whatever to my making a digital examination of his mouth; but, although I inserted the tip of my forefinger into all the cavities of his mouth, one after the other, I could detect no glass whatever, and was forced to the conclusion that the fragments had actually been swallowed.

DR. WATSON: In reference to the cases spoken of by Dr. Cheever I would like to say that there have been reported about twenty such cases in incarcerated or strangulated hernia.

NEEDLE FRAGMENTS IN THE TISSUES LOCALIZED BY MEANS OF MAGNETISM.

DR. MONKS exhibited several fragments of needles which he had removed from patients, having previously localized these fragments by means of a magnetic indicator while they were still within the tissues. The fragments, which were mounted in a box under a glass cover, were passed about for examination, a little magnetic indicator being passed with

them. Each member was, therefore, able to test for himself the attractive force exercised by the fragments upon the indicator.

ANNOUNCEMENT.

DR. MONKS: I want to say a few words to the Society concerning a matter which I am sure will be of interest to them. One of the functions of the Philadelphia Academy of Surgery is to award every five years the Samuel D. Gross Prize, of \$1000, "to the writer of the best original essay, not exceeding one hundred and fifty printed pages, octavo, in length, illustrative of some subject in Surgical Pathology or Surgical Practice, founded upon original investigations, the candidates for the prize to be American citizens." I think we must all agree that it is advantageous for any surgical society to have some such connection with the past, some worthy source from which it may gather inspiration for work in the future. This idea is, I think, beautifully expressed in a bas-relief in the reception room of President Lowell's house in Cambridge. This bas-relief represents a young man, who, about to spring forward, reaches to receive a lighted torch from the outstretched hand of an old man who has about run his course!

Although some of the members of the Boston Surgical Society are well along in years, yet the Society itself is of such recent formation, that, in a sense, it may perhaps be looked upon as youthful, and as therefore ready to receive from the past the responsibility of being one of the channels through which the high ideals and traditions of the past may be transmitted to the future.

As Boston has been a center of surgery ever since the days of ether, and even before, and as the surgery in those days was done by men whose character and achievements have reflected great credit and dignity upon Boston, it seems most desirable that some definite connection with this group of men should, if possible, be established. As no one could represent them better than Dr. Henry J. Bigelow, it gives me much pleasure to announce that Dr. Wm. Sturgis Bigelow has offered to establish a prize in the form of a gold medal, in memory of his father, Dr. Henry Jacob Bigelow, to be awarded from time to time by The Boston Surgical Society for valuable original work in surgery or connected with it.

What action will the Society take in this matter?

DR. SCUDDER: We have associated ourselves together as The Boston Surgical Society, an exclusive body, limited in membership, for the promotion of the art and of the science of surgery, and of professional good fellowship.

We are to be congratulated that our Society has been honored by being chosen custodian of the Henry Jacob Bigelow Medal—for the custodianship of this medal will contribute to the permanence of the Society, and the award of this medal will undoubtedly be a factor in furthering productive surgical investigation.

Therefore, Mr. President, I offer this motion:

That this trust be accepted;

That the Council of the Society be requested to forward an appropriate letter of acceptance to Dr. W. S. Bigelow, the donor, expressing the appreciation of the Society;

And, that the Council formulate the conditions concerning the award of the medal, which, after proper discussion by the Society, shall be submitted to Dr. Bigelow for his approval.

DR. PAUL THORNDIKE spoke of the gift as a fitting tribute from a generous son to a famous father, and stated that the Society should feel itself honored to be named the administrator of such a gift. He seconded Dr. Scudder's motion, and stated that he hoped that the Council would take every care to invest the gift with the dignity and the authority its importance deserves.

DR. WATSON: I am very glad, Mr. President, to have the opportunity to pay my tribute to the distinguished father of Dr. Wm. Sturgis Bigelow, who has made this generous offer to the Society.

If one recalls the pictures of certain international Medical Congresses, there stands out from their members one group of men. This group is composed of Pasteur, Lister, Virchow, Von Langenbeck, Sir William Macewen, Sir William McCormac, and Henry J. Bigelow. To my mind these were the most distinguished and notable figures in these gatherings; and, in certain respects, Dr. Bigelow was to be counted among the foremost of them.

Dr. Bigelow possessed certain attributes that gave him a distinction almost unique. Among them was an intellectual acumen such as one rarely meets with. The most striking characteristic of his mind was its remarkable and unerring manner of seizing upon the essential point of any problem, and of concentrating his attention upon that point until he had established it to his satisfaction in all its bearings. When a proposition interested him he spared no pains in perfecting the less essential details of the matter. Sometimes, however, he would rest content with having solved the vital part of the problem, and would turn over the detail of it to be worked out by some one else.

As a teacher, one of his most telling powers was that of graphic, often dramatic, expression, and of terse epigrammatic phrase. One of the evidences of the value of this way of bringing home to his students the truths he desired to impress upon them may be seen in the fact that of the words of all the teachers from whom I have received instruction, his are the only ones that I can today, after an interval of thirty odd years, repeat verbatim. Few of those who heard his terse summing up of the methods for treating the arm after reduction of a dislocated shoulder will ever forget the few words that he used to describe them at the end of one of his lectures: "Gentlemen," he said, "many pages have been written and many illustrations have been made to show how the arm is to be treated after reduction of a dislocated shoulder. The whole thing consists in this: Pad in the axilla, elbow to the side, arm in a sling. Good morning, gentlemen!"

As an operator his co-ordination of mind and hand was more perfect than that of any other surgeon it has been my fortune to see. He added grace and an unerring precision of movement to his other qualities, and thus made his operative work yet more impressive.

His sense of touch and the clearness of his mental vision gave him a power of making, almost instantly, diagnoses that others failed to make even after careful study.

Apart from these attributes he had a commanding personality, and always "looked the master."

It is a fortunate thing for this Society to have such a man commemorated, as he will be by this gift made by his son. This gift should serve as a stimulus to greater endeavor, on the one hand; and, as a link with the past and with the man who was

the foremost and most remarkable of American surgeons in his day. I hope that a fitting expression of our appreciation of this generous gift will be made to Dr. Wm. Sturgis Bigelow. The motion was then put to vote, and was unanimously carried. The meeting was then adjourned.

Book Reviews.

Diseases of the Bronchi, Lungs and Pleura. By FREDERICK T. LORD, M.D. Illustrated with 93 engravings and 3 colored plates. Philadelphia and New York: Lea and Febiger. 1915.

Dr. Lord has written an admirable book which has a definite place in medical literature. There have appeared recently many works in English on the diseases of the heart, but there has been no satisfactory previous work in English on diseases of the bronchi, lungs and pleura. Dr. Lord has been very wise in omitting discussion of pulmonary tuberculosis under a special heading but, of course, pulmonary tuberculosis is adequately discussed in its relation to other conditions. Tuberculosis of the lungs is of such importance that by common consent it forms a special field of its own. One of the most satisfactory features of the book is the excellent subdivision of the discussion; rare conditions are adequately and thoroughly discussed, but always with due regard to their frequency and importance. One cannot fail to be impressed with the thorough consideration of the literature, always backed up, however, by the writer's extensive clinical experience and his own researches. There is abundant use of pathological material. The form of presentation is clear and concise and the book can be heartily recommended as an authoritative exposition of the subject.

Practical Text-Book of Infection, Immunity and Specific Therapy, with Special Reference to Immunologic Technic. By JOHN A. KOLMER, M.D. With 143 original illustrations, 43 in colors. Philadelphia and London: W. B. Saunders Company. 1915.

Dr. Kolmer states in his preface that the purpose of the book is three-fold, namely: "(1) To give to practitioners and students of medicine a connected and concise account of our present knowledge regarding the manner in which the body may become infected, and the method in turn by which the organism serves to protect itself against infection or strives to overcome the infection if it should occur, and also to present a practical application of this knowledge to the diagnosis, prevention and treatment of disease. (2) To give to physicians engaged in laboratory

work and special workers in this field a book to serve as guide to the various immunologic methods. (3) To outline a laboratory course in experimental infection and immunity for students of medicine and those especially interested in these branches." On the whole the writer has carried out his purpose well. While he has discussed the various theoretical considerations, yet the main emphasis is upon the established facts and the practical data of this complicated field. Dr. Kolmer has the very great advantage of having given a course covering this same field in the Medical School of the University of Pennsylvania. Consequently, he is perfectly aware of the confusing complexity of many aspects of the subject. His explanations are simple, direct and intelligible. It is a clear exposition of a difficult subject, which is even more complex because our knowledge of it is so recent and so little digested. The book will appeal especially to those who desire to know the general principles of immunity and to secure adequate information about the various reactions and to those who desire to have a standard reference book which will assist them in immunological research.

Text-Book of Surgical Operations. Illustrated by Clinical Observations, for Physicians and Students. By PROF. FEDOR KRAUSE, Privy Medical Councillor; Directing Physician Augusta Hospital, Berlin, in association with EMIL HEYMANN, M.D., Chief Physician, Augusta Hospital. Translated into English and edited for American readers by ALBERT EHRENFRIED, A.B., M.D., F.A.C.S.; Assistant Visiting Surgeon, Boston City Hospital; Junior Assistant Surgeon, Children's Hospital; Surgeon, Boston Consumptives' Hospital; Assistant in Surgery, Harvard Graduate School. In six volumes. Vol. I.

It will seem to many Americans a little strange to read that Fedor Krause, one of the best and boldest operators of the world, is known in Berlin as the "Directing Physician" of the Augusta Hospital, and that his associate in the publication of this most extensive of operative surgery text-books, is the "Chief Physician" of the same institution; it is a little like going back to the old days when the surgeon was almost unknown.

Krause is universally acknowledged both as a general surgeon, and as an authority upon surgery of the head; upon the latter subject he has published three volumes, the last of which was reviewed in the BOSTON MEDICAL AND SURGICAL JOURNAL two years ago. Three volumes limited to the head, would seem to warrant at least six covering the surgery of the entire body. Unfortunately, the average man will be disinclined to buy for himself so large a work, and the six

volumes will be more limited in their circulation than their worth would justify.

Krause believes that specialism in surgery is not desirable; he makes this definite statement in his preface; he has written what he calls a text-book of operative surgery, illustrated by actual cases, with symptoms, operative detail, after-treatment, result, and notes of autopsy in fatal instances. This method necessarily adds interest and zest to what have often been in the past dry and detached descriptions. Gynecology, ear, nose and throat operations all become part of an enormous whole, and a painter (Max Landsberg) provides illustrations with reckless prodigality, from sketches made during the actual operations; these pictures are reproduced by a most finished lithographic (German) process, and necessarily add to the expense of the book; they stand to the text in the same relation as Broedels' pictures in America—as actual works of art.

The first four chapters consider the Preparation for Operation, Anesthesia, Asepsis, and devote a few pages to after-treatment; next appears a chapter upon Wounds and Fractures of the Face and Skull; Plastics of the Face, an exceedingly interesting chapter; Surgery of the Eye, Ear, Nose and Throat; Surgery of the Trifacial Nerve, and Extirpation of the Gasserian Ganglion. This completes the first volume of 250 pages.

Our grateful thanks go to the publishers for the flat soft paper and the large clear type, as well as for the excellent and practical binding of the book; and particularly to the translator, Ehrenfried of Boston,—a young man of ability and tireless activity, to whom we owe the English translation, which preserves so well the spirit of the original.

The book, of course, takes its pace immediately as one of the very best of the many good text-books of German Operative Surgery.

A Laboratory Manual and Text-Book of Embryology. By CHARLES W. PRENTISS, A.M., Ph.D. Octavo of 400 pages with 368 illustrations, many of them in colors. W. B. Saunders Company. 1915.

Since the appearance of Minot's work on embryology, this laboratory manual is the most important contribution which has been made to the text-book literature on this subject. It follows the general method of Minot's book and especially elaborates the study of pig embryos, with dissecting methods based on the work of Drs. Minot, Lewis and Thyng. The chapters on human organo-genesis are partly based on Keibel and Mall's "Human Embryology." The volume is beautifully illustrated with 368 figures, many of which are colored. It is a valuable addition to the literature of this fascinating subject whose development has been so notably the work of American medical science.

Papers on the Influence of Smoke on Health.

Edited by OSCAR KLOTZ and WM. CHARLES WHITE, Mellon Institute of Industrial Research and School of Specific Industries, University of Pittsburgh. 1914.

This bulletin (No. 9) of the Mellon Institute of Industrial Research represents the smoke investigation conducted under its auspices at the University of Pittsburgh. The papers represent the work done by several physicians and laboratory investigators. Mr. Cohoe considers first the relation of atmospheric smoke and health. Mr. Oskar Klotz studies the subject of pulmonary anthracosis (misprinted arthracosis), which he regards as a community disease. Mr. W. L. Holman studies the bacteriology of soot, which he concludes to have a definite bactericidal action, due not only to the contained acids, but to some other agent, probably a phenol. Dr. Samuel R. Hathorne (whose name is also misprinted) presents some histological evidence of the disease importance of pulmonary anthracosis, which he regards as not in itself detrimental to health in an otherwise normal lung. In acute inflammatory conditions he believes it is seriously detrimental from its obliteration of lymphatics, but in tuberculous lesions it is either passive or actually assists healing by providing an additional stimulus to fibrosis and encapsulation, thus aiding the localization of the process. This article is illustrated by twenty photomicrographs. Dr. William C. White and Messrs. C. H. Marcy and Paul Shuey present brief statistical reports on the influence of varying densities of city smoke on the mortality from pneumonia and tuberculosis and on the influence of smoke on acute and chronic lung infections. The two latter papers are reprinted from previous publications. This research report as a whole is interesting, but unfortunately has the appearance of having been hastily printed without careful proof-reading.

Text-book of Massage. By A. MÜLLER, M.D., Munich. Bonn: Marcus and Webers. 1915.

This admirable German text-book of massage presents at length, for those who can avail themselves of it, a complete treatise of the latest theories and technic of this important subject. It is illustrated by 341 outline anatomic cuts after original drawings by the author. The text accompanying each of these full-page illustrations describes schematically the purpose of the manipulation, position of patient and physician, the tissues involved and the technic of the procedure. Such a work is, from its nature and method, more complete, though for the most part not so available to American practitioners, than many of the admirable English works, notably that of Dr. Douglas Graham, which have appeared in recent years.

THE BOSTON Medical and Surgical Journal

An independently owned Journal of Medicine and Surgery, published weekly, under the direction of the Editors and an Advisory Committee, by the BOSTON MEDICAL AND SURGICAL JOURNAL SOCIETY, INC.

THURSDAY, APRIL 29, 1915.

EDITORS.

ROBERT M. GREEN, M.D., *Editor-in-Chief.*
GEORGE G. SMITH, M.D., *Assistant Editor.*

WALTER L. BURRAGE, M.D. *For the Massachusetts Medical Society.*
FREDERICK T. LORD, M.D.

COMMITTEE OF CONSULTING EDITORS.

WALTER B. CANNON, M.D. ALLAN J. McLAUGHLIN, M.D.
HARVEY CUSHING, M.D. ROBERT B. OSGOOD, M.D.
DAVID L. EDSALL, M.D. MILTON J. ROSENAU, M.D.
REID HUNT, M.D. EDWARD C. STREETER, M.D.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States. \$6.56 per year for all foreign countries belonging to the Postal Union.

The editor will be in the editorial office daily, except Wednesday and Sunday, from one to two-thirty p.m.

Papers for publication and all other communications for the Editorial Department should be addressed to the Editor, 126 Massachusetts Ave., Boston. Notices and other material for the editorial pages must be received not later than noon on the Saturday preceding the date of publication. Orders for reprints must be returned in writing to the printer with the galley proof of papers. The Journal will furnish the first one hundred reprints for half the cost price.

All letters containing business communications, or referring to the publication, subscription, or advertising department of the Journal, should be addressed to

ERNEST GREGORY, *Manager.*

126 Massachusetts Ave., Corner Boylston St., Boston, Massachusetts.

PUBLIC HEALTH ADMINISTRATION IN NEW YORK.

In another column of this issue of the JOURNAL we are glad to publish the address on dispensaries as a growing factor in curative and preventive medicine, delivered at a conference held in this city in January under the auspices of the board of managers of the Boston Dispensary, by Dr. S. S. Goldwater, commissioner of health of New York City. The growth of dispensary work in recent years has been one of the notable facts in the development of medical institutions. In many of the larger cities from one-fifth to one-third of the population are annually patients at various such institutions. While the importance of dispensaries in the cure and prevention of disease is becoming more fully recognized, not only by patients but by physicians, their growth has been so rapid and so recent, that their standards are as yet less well defined than those in many similar fields of ser-

vice. In recognition of this condition, this meeting was arranged for the consideration of dispensary work in its relations to medical science, social service, public health and education.

Dr. Goldwater, as superintendent of the Mt. Sinai Hospital of New York first gave his institution a place among the leading hospitals of the country and by promoting higher standards of dispensary service became a leader in the domain of public medicine. In his address Dr. Goldwater describes in detail the growth of the New York Dispensary system and discusses the subjects of administrative and clinical efficiency.

Later as health commissioner of New York City, Dr. Goldwater has earned distinction in constructive work for the the promotion of public health. Perhaps the four most notable aspects of his work in this capacity in New York City have been, first, the establishment of full-time service on the part of all bureau chiefs and department officials; second, public education in hygiene and methods of right living; third, the establishment of an advisory council to co-operate with the health commission and act as intermediates between the latter and various other agencies of public activity such as insurance companies and settlement and social workers; and fourth, the improvement of public transportation by the prevention of overcrowding and the requirement of ventilation and cleanliness in all public conveyances.

In this conjunction it is of interest to compare the public health administration of New York State with that of New York City. In 1913 a law was passed establishing a public health council, a sanitary code, and providing for the enforcement of the code by twenty sanitary supervisors having jurisdiction over as many districts.

"The Public Health Council consists of the Commissioner of Health and six members appointed by the Governor. The law provides that three of the appointive members shall be physicians experienced in sanitary science, and another of the appointive members a sanitary engineer. Dr. Simon Flexner, Director of the Rockefeller Institute; Dr. T. Mitchell Prudden, Vice-President of the Board of Scientific Directors of the Rockefeller Institute; Dr. Wilhelm Gaertner of Buffalo, and Dr. Hermann M. Biggs, Commissioner of Health, constitute the four physicians of the Council. Professor Henry N. Ogden of Cornell University is the Sanitary Engi-

neer appointed by the Governor. Mrs. Elmer Blair of Albany, President of the General Federation of Women's Club, and Homer L. Folks, Secretary of the State Charities Aid Association, complete the membership.

"The Public Health Council has no executive, administrative, or appointive duties. Its chief functions are 'to establish, and from time to time amend sanitary regulations,' to be called the Sanitary Code, and 'to prescribe by regulations the qualifications of Directors of Divisions, Sanitary Supervisors, local Health Officers hereafter appointed, and public health nurses.'"

The system of public health administration, thus designed, may fairly be regarded as ideal and has already been imitated in the state health commissions of Kansas, Maryland, Massachusetts, Michigan, New Jersey, and Texas. Unfortunately it has no sooner been hardly more than established in New York, than it is attacked by a series of five bills introduced into the General Assembly at Albany by Representative Hinman, radically amending the new law. These proposed amendments were described as follows in the *New York Times* of Sunday, April 11:

"The Hinman amendment of Assembly Print 1940 reduces the number of Sanitary Supervisors to ten, cuts the salary from \$3000 to \$2500, and makes the establishment of their districts discretionary instead of mandatory. Similarly, another Hinman bill, Assembly Print 1835, makes discretionary instead of mandatory the establishment of the divisions of the department, namely, those of child hygiene, public health nursing, tuberculosis, vital statistics, communicable diseases, administration, health education, sanitary engineering, and laboratories and research. The Commissioner is empowered by the amendment to eliminate or combine any of these divisions.

"The Hinman amendment, Assembly Print 1942, abolishes the duties of the Council in prescribing the qualifications of experts to be appointed to the more responsible positions requiring technical experience in sanitary science.

"Assembly Print 1943 amounts to the virtual abolition of the other important function of the Council relating to the sanitary regulation. Within the last year the Council has established seven chapters of the Sanitary Code, containing 119 regulations relating to the control of the spread of communicable diseases, maintenance of sanitary standards for milk and cream, the

practice of midwifery, conduct of labor camps, prevention of nuisances, and miscellaneous practices.

"The Council now has power to amend these regulations if the necessity arises. The present health law provides that these regulations, as soon they are established by the Council, become operative without legislative action. Mr. Hinman's amendment takes away all the legal effect of these sanitary regulations. The amendment reads: 'All such regulations, including those heretofore embodied in the Sanitary Code, shall be reported by the Council to the Legislature for approval or rejection in whole or in part.'

"The Hinman amendment provides that in emergencies, such as epidemics, the sanitary regulations of the Council shall for a time have the force and effect of law, without the approval of the Legislature. The legal effect of such emergency regulations ceases ten days after the opening of the Legislature.

"Opponents of the amendment contend that the most important phase of modern sanitation is not so much the control of epidemics after they have started as the prevention of their occurrence. As contrasted with the present law, the Hinman amendment fails to provide for the development of this larger field of preventive medicine, for prevention requires action to forestall emergencies.

"The fifth Hinman bill requires the Commissioner and the directors of each of the different divisions 'to devote his entire time to the duties of his office.' It is contended that the enforcement of this would bring about the retirement of the present Commissioner, Dr. Hermann M. Biggs. For more than twenty-five years Dr. Biggs was identified with the New York City Health Department until he accepted the appointment as State Commissioner of Health. Under his technical leadership as Chief Medical Officer the death-rate of New York City was reduced below that of the State at large. Comparison of the vital statistics of the city and the rural communities show that in very recent years the progress of medical science has made it possible in enlightened communities, however crowded or populous, to secure by intelligent sanitary regulation and education, a reduction of the death-rate below that of rural communities."

In his recent thirty-fifth annual report, Dr.

Biggs commented particularly on these facts, and in continuation spoke as follows of the paramount importance of public health education in securing their benefits for the communities:

"Simple measures in the main—difficult in their application to large masses of the population only because they involve public health education—will assure these benefits. The education of the public to the risks of neglect, and to the advantages and ways of healthful living, is necessarily a slow process. For its successful accomplishment by the sanitary authorities, the requisites are adequate funds, broad powers, and an efficient organization carrying guidance and inspiration into every school, workshop, store, and factory, as well as into every home, whether in the city, town, or remotest countryside.

"Health and education should go hand in hand and on the same plane; but while millions are devoted to education, only thousands are spared for health. A hundred millions are spent by the State on a large canal; another hundred millions on good roads; tens of millions on institutions for the care of mental and physical derelicts, while a few hundreds of thousands only are devoted to the promotion of health. This is not said in criticism of these larger and perhaps justifiable public expenditures, but to emphasize the newly recognized necessity which the welfare of every citizen involves."

The admirable public health which is being done under Dr. Goldwater in New York City, and under Dr. Biggs throughout the remainder of the State, should not be hampered at this juncture by meddlesome and mischievous legislation. It is earnestly to be hoped that the present political attempt to do so may meet with the decisive defeat which it deserves.

AN ANTITYPHUS VACCINE.

THE experimental work of Anderson and Goldberger and of others, more particularly Nicolle and Conseil, demonstrated a solid basis for the conclusion that the virus of typhus fever is present in the blood, at least throughout the febrile period. A number of months ago Dr. Henry Plotz, a young bacteriologist connected with the Mount Sinai Hospital, New York, re-

ported the discovery of the specific micro-organism of typhus, and at a meeting of the New York Pathological Society held on April 15, 1915, not only was this discovery abundantly confirmed, but announcement was made by Plotz that he had succeeded in preparing an antityphus vaccine of similar character to the antityphoid vaccine, the prophylactic value of which is now so generally recognized. Its efficacy cannot as yet, of course, be regarded as established, since there has been no opportunity for testing it practically. It is a fact, however, that just previous to sailing, Dr. Hans Zinsser, professor of bacteriology in Columbia University and also president of the Pathological Society, together with other members of the Rockefeller Institute expedition to combat typhus in Servia, were inoculated with the vaccine. Plotz himself was the first person to be vaccinated.

After Anderson and Goldberger had announced their experimental researches showing that Brill's disease and typhus were identical, Plotz, while still a medical student at Columbia, became deeply interested in the subject, and after his graduation, in 1913, began a line of original investigations in the bacteriological department of Mount Sinai Hospital. He had the opportunity of examining the blood of a considerable number of patients suffering from Brill's disease, and it was not very long before he succeeded in isolating a bacillus which he demonstrated, by results noted from the inoculation of guinea-pigs and monkeys, to be the causative agent of the disease. As Dr. Libman, associate pathologist to Mount Sinai, expressed it at the meeting of the Pathological Society, "The discovery was no chance discovery. Dr. Plotz came to the hospital to discover the cause of Brill's disease, and he did it at the first try." Not long after this, through the courtesy of Dr. O'Connell, Health Officer of the Port, Plotz obtained in the Quarantine hospital specimens of the blood of several typhus patients, who had brought the disease from Europe, and from this blood isolated a bacillus which proved to be identical with that found in Brill's disease. Apparently, the two diseases, which differ so greatly in severity, are caused by two strains of the same microbe. The name, Brill's disease, will therefore be abandoned, and it is possible that the affection which has been so designated will now be known as endemic typhus, in contradistinction to epidemic typhus, the classic formidable

disease. At the meeting Dr. Brill himself expressed the opinion that this was the first work which had absolutely established the identity of the two types of typhus fever, stating that while he had long ago admitted that the two diseases were related, he had always contended that their identity had not been proved by the experiments of Anderson and Goldberger. Dr. William H. Welch of Johns Hopkins was asked to name the newly acknowledged micro-organism, and he gave it the designation, bacillus typhi exanthematosi.

That this bacillus is the causative agent of typhus, established by incontestable scientific proof, is accepted as final, as is shown by the fact that the discovery has received the endorsement of such men as Noguchi and Meltzer of the Rockefeller Institute, William H. Park, head of the research laboratories of the New York City Department of Health, and Mandelbaum and Libman, pathologists to Mount Sinai Hospital. All these were present at the meeting and warmly congratulated Dr. Plotz and the two other investigators associated with him in his work, Drs. P. K. Olitzky and George Baehr; and Noguchi was the first to express his gratification at what had been achieved. This was the first announcement of the discovery before a scientific body, and it cannot but be acknowledged that the achievement is one reflecting the highest honor on American medicine. Dr. Plotz is a native of Paterson, N. J., and it is certainly remarkable that so important a contribution to science should have been made by one only now in his twenty-fifth year. Should the typhus protective vaccine prove to afford the same immunity as is observed in the case of that against typhoid, the good it may accomplish is almost incalculable.

THE MEDICAL PROFESSION AN AGENT FOR PEACE.

INTERNATIONALIZING of the medical profession, already favored by medical congresses and the modern facility of travel, has been well advanced by the present war in Europe. Physicians now serving in the armies on the continent treat friend and foe alike. Are they not the only real neutrals who are engaged in the struggle? Men skilled in mathematics, physics, chemistry and other practical sciences are vying with

each other to perfect methods of destroying life and property on a scale never before seen in the history of the world. Lawyers are engaged in setting forth the justice of the cause of one or the other nation and in furnishing arguments for their moral or commercial advantage. The clergy is divided in its sympathies, and its ability to minister to the religious needs of all is impaired because of the many sects into which the Christian church is split and the diverse partisan considerations arising out of such an ununited state. The peace societies and the propaganda of Mr. Carnegie and others have been unsuccessful in averting war or in mitigating its severity. Even the men of letters are ranged on one side or the other and are striving in their worship of a national ideal to forget their belief in a universal God.

There are highly cultured and civilized men and women among the people of all nations, and individual morality and right living have progressed to a higher plane in recent times. The morality of nations, however, is about where it was in the days of Caesar when physical might meant right.

Surgery, medicine, bacteriology, hygiene, have never been employed for other purpose than the saving of life. They have no national ambitions, no national ideals; they belong to all. May this not be the time for them to march to the battle against self interest and militarism with the vision of a modern Emperor Constantine, "*In hoc signo vinces*" and a red cross.

Groups of eminent American medical men are now giving their services in England, in Paris, in Berlin, in Vienna, in Petrograd and in Servia, caring for the wounded, assisting in the problem of sanitation and in stamping out epidemics of infectious disease. The profession of medicine represents humanity as a whole; its aim is solely the alleviation of suffering and the preservation of life. It is opposed to war and to killing and maiming.

In a recent issue of *Science* Dr. S. J. Meltzer, of the Rockefeller Institute, suggests that the medical profession of the United States, a neutral nation, take the initiative in forming a medical brotherhood devoted to international morality, appealing to the physicians of the belligerent nations to join after the war is over. Perhaps such an organization might be able to teach that although life is a perpetual strife, the fittest may achieve survival by other means than by bloodshed.

ORGANIZED OBSTETRIC AND PREGNANCY CARE IN MASSACHUSETTS.

THE experience of those who have studied conditions of the law in Massachusetts shows that approximately five hundred midwives are practicing in Massachusetts today, and that a large proportion of these are unclean and inefficient. The fact that this is the case reflects distinctly on the medical profession and brings up the question whether practicing physicians properly appreciate the needs of the community and are endeavoring to meet them. If this is the case, why are these midwives allowed to exist?

It is recognized, however, that they cannot be eliminated until a better service is provided by the medical profession. The people in their ignorance of medical affairs feel that they need just such a service as the midwife provides. Is the medical profession endeavoring to show that the people really need a better service?

The article on the Care of Prospective Mothers in this issue of the JOURNAL is put forward by the medical profession, and others in the state, as one method to meet this situation. The only objection, so far as we know, which is raised against the development of such work in the interests of the public, is that it makes an organized effort to meet this condition, and some doctors feel opposed to this organization because it may take away from them a certain amount of their practice. Even if appeal is made to the selfish motives, there is another way of looking at this scheme.

It ought to be clearly recognized that any scheme which leads people to appreciate better service offered by doctors would lead to the more general use of the doctors for obstetric cases. The profession will have to give at first a certain amount of service in developing these clinics, but this will be returned to the medical profession many fold.

Still another result of such organization of obstetric work would be abundant material for teaching obstetrics to the young practitioners of any locality through a properly organized and supervised service, which is the only way obstetrics can be thoroughly taught. The men allied with these clinics might become recognized in each community as being competent in obstetrics. The incompetent would naturally work in other lines. Thus a better class of obstetric practitioners would develop in each community, and the medical profession gain prestige.

THE BOSTON SURGICAL SOCIETY AND THE HENRY JACOB BIGELOW MEDAL.

THE BOSTON SURGICAL SOCIETY, an organized and incorporated body whose membership represents the hospitals of Boston, is to be congratulated; for to it has been offered by Dr. Wm. Sturgis Bigelow, of Boston, the privilege of awarding from time to time a medal to that individual, who, in the opinion of the Society, makes such notable contribution to the science or the art of surgery as to be entitled to receive it. Dr. Bigelow intends to deposit an adequate fund for this purpose. The medal is to be known as THE HENRY JACOB BIGELOW MEDAL, in memory of the donor's father.

It is hardly necessary to add that the stewardship of the Bigelow medal has been accepted by the Society with enthusiasm. In the report of the transactions of the Society, which appears in another column of this issue of the JOURNAL, is published a statement about the medal made to the Society at the time of the presentation of Dr. Bigelow's offer. Certain conditions concerning the award of the medal are as yet undecided, but it is expected that they will be announced shortly, and further information about them will be duly presented in the columns of the JOURNAL.

MEDICAL NOTES.

NEW YORK DEATH-RATE.—Among those causes of death that swell in great measure the mortality returns, there was not a single one during the past week that did not show an increase in the number of reported deaths as compared with the returns for the corresponding week of the year 1914.

The most notable increases were among the following causes: lobar pneumonia, in which the increase was practically double, as was also that from acute bronchitis. The number of deaths from broncho-pneumonia increased about 30%, from pulmonary tuberculosis 35%, from organic heart disease about 17%, from chronic Bright's disease about 12%.

The number of deaths reported during the week was 1778, as against 1566 during the corresponding week of 1914, the death-rate increasing from 14.63 to 15.98 per one thousand of the population.

The death-rate for the first sixteen weeks of 1915 was 14.66 per one thousand of the population, as against a rate of 15.47 during the corresponding period of 1914, a decrease of .81 of a

point; the decrease in the death-rate for this year up to the last week of March was 1.5 of a point, so that the effect of the increased virulence of influenza during the past three weeks has been to change this decrease in the death-rate by almost 50% from Jan. 1 to date.

RADIUM INSTITUTION IN MANCHESTER (ENG.).—It is reported in *Nature* that the movement for the establishment of a radium institution in Manchester has received hearty support from the public and the press. The committee appointed to carry out the scheme collected about £30,000. One thousand pounds was spent in equipping several rooms for the use of the department in the Royal Infirmary and 800 milligrams of radium metal, costing about £21,000, were purchased from an American firm. The standardization of the radium was done in the laboratories of the University of Manchester. The committee is now arranging to distribute the radium, either in solid form as applicators, or as emanation tubes from the liquid form, to the other hospitals in Manchester and the district.

LONDON DEATH RATES IN FEBRUARY.—Statistics recently published show that the total death rate of London in February, 1915, was 20.7 per thousand inhabitants living. Among the several districts and boroughs the highest rate was 24.8 in Bermondsey, a populous southern slum, and the lowest was 15.8 in Hampstead, an open residential district on the north.

FRENCH VITAL STATISTICS.—Report from Paris states that on April 16, the vital statistics of France for the first half of 1914 were published. During that period there were 2000 fewer marriages, 4000 more births and 20,000 more deaths than during the corresponding period of 1913. The net diminution in the population of France during this time was about 17,000, while the population of Germany increased nearly 500,000 during the same period. This six months' period is the last in which what may be considered as normal peace conditions prevailed in France. Subsequent statistics will show not only the preëxisting trend of the population, but the effect of the European War upon all forms of vital statistics.

BUBONIC PLAGUE IN HAVANA.—Report from Havana states that on April 19 three cases of bubonic plague were discovered in Vedado, a fashionable suburb of the city. This focus of infection, which appears confined to a small group of houses has already been isolated.

SMALLPOX AT SAN FRANCISCO.—Report from San Francisco states that on Apr. 19 a case of smallpox was discovered aboard the steamship *Chiwo Maru*, which arrived at port on that day. The patient was isolated and 336 passengers on the steamer were vaccinated.

NEW YORK DRUG LAW.—Report from Albany, N. Y., states that on April 17 Governor Whitman signed a bill so amending the present state drug law as to make it a felony instead of a misdemeanor to sell habit-forming drugs to persons under sixteen years of age.

MEDICAL SOCIETY OF THE MISSOURI VALLEY.—The spring meeting of the Medical Society of the Missouri Valley was held at Omaha, Neb., on March 25 and 26, under the presidency of Dr. Granville Ryan of Des Moines, Iowa, with an attendance of over three hundred members and guests. Addresses were presented by Dr. F. H. Albee of New York on bone grafting; by Dr. C. S. Williamson of Chicago on cardiac overstrain; by Dr. Paul Paquin of Kansas City on early symptoms of tuberculosis; by Dr. Reuben Peterson of Ann Arbor on craniotomy; by Dr. A. A. Law of Minneapolis on the status of the autograft, and by Dr. E. G. Blair of Kansas City on goitre. It was voted to hold the fall meeting of the society in Des Moines.

PYGOPAGUS AND XIPHOPAGUS.—The local interest recently excited by a case of pygopagus twins at the Children's Hospital is paralleled by that in a case of xiphopagi reported on April 19 from Houston, Texas. The Texan twins, like those in Boston, are three years old and are reported to be equally well developed. They were born in Havana of Spanish parentage. It is stated that the operation of xiphopagotomy is soon to be performed upon them.

LEGACY TO BUREAU OF SOCIAL HYGIENE.—The will of the late Mrs. John D. Rockefeller, which was filed in New York City on April 17, contains a residuary bequest to numerous charitable and educational institutions, including the American Bureau of Social Hygiene.

YELLOW FEVER IN LOUISIANA.—Report from Morgan City, La., states that on April 15 two cases of yellow fever were discovered in that port aboard the schooner *Colwell*, recently arrived from Demerara, British Guiana. One member of the crew had died on March 25 and was buried at sea. The two remaining cases have been isolated.

NATIONAL ADMINISTRATION OF NEW YORK QUARANTINE.—On Tuesday evening of last week, April 20, a meeting was held at the New York Academy of Medicine for the purpose of urging that the quarantine station of the Port of New York, now in the hands of the New York State Government, be transferred to the United States Public Health Service, a step which the present conditions in Europe make especially important at this time. At this meeting Mr. Henry James, Jr., who has recently returned from an official tour of inspection through the belligerent countries of Europe, made the opening address on "Present health conditions in Europe, and their

relation to this country." Dr. William C. Woodward, health officer of the District of Columbia and former president of the American Public Health Association, spoke on "The menace of inadequate quarantine and the meaning of an efficient quarantine to the entire country"; and the Hon. William H. Taft on "The relation of the national government to quarantine and other public health agencies."

EUROPEAN WAR NOTES.—On April 17 the war relief commission of the Rockefeller Foundation published a report of its investigation of present conditions in Serbia, where typhus, typhoid, recurrent fever, smallpox, scarlet fever and Asiatic cholera are present. It is estimated that there are in Serbia at present from 25,000 to 30,000 cases of typhus fever, from which there are 100 deaths daily in Nish alone.

"One day during the visit of the commission it was reported that the cemetery at Nish contained 250 unburied bodies of typhus victims, the force of grave diggers being entirely unable to keep up with the work.

"In Belgrade, in one hospital were 165 cases of typhus, with a larger aggregate number in several other hospitals.

"In Skopje, Dr. Barrie, an English physician who has been in Skopje several months at the head of a medical mission of the British Red Cross, estimated the number of typhus cases on Feb. 24 at 2000.

"Valjevo, a town in that part of Serbia which was for a time held by the Austrian army, is reported to be the most serious centre of the epidemic of typhus. Substantially the entire civilian population there are involved in the disease. Without medical care, with no direction or resources for setting on foot sanitary measures, remote and helpless, the population is being decimated, while the epidemic spreads in rapidly widening circles. Every community on the main lines of travel is in the clutches of typhus. Into the mountain places and the villages distant from the railroads the disease is being carried by the moving troops and bullock drivers and by the straw-lined carts in which the sick and the well are transported, and it is said to be prevalent in most of them already."

On April 27, two additional Red Cross hospital units, consisting of six surgeons and twenty-four trained nurses, sailed from New York for Liverpool aboard the American line steamship *St. Louis*. These units will be attached to the Belgian Army and will be stationed for six months' duty at the Ocean Hospital at LaPanne. The surgeons are Drs. Albert R. Goodman of New York, Robert W. Hinds of Buffalo, William H. Morriss of Baltimore, John D. Spellman of Cincinnati, William T. Fitzsimmons of Kansas City and Earl V. Morrow of Portland, Oregon. Dr. James E. Daniel of Greenville, S. C., also sailed on April 17 for duty at the American Women's Hospital, Paignton, Devonshire, England.

At the meeting held in the Boston Medical Library on April 14 the sum of \$7,200 was raised for the Belgian Red Cross.

EUROPEAN WAR RELIEF FUNDS.—On April 24 the totals of the principal American relief funds for the European War reached the following amounts:

	N. Y.	N. E.
Belgian Fund	\$1,023,174.92	\$252,855.25
Jewish Fund	617,747.53	58,824.23
Red Cross Fund	481,402.23	131,097.09
American Ambulance	386,127.89	
Committee of Mercy	146,502.48	
Polish Fund	45,627.28	12,904.66
Serbian Fund	39,452.11	11,756.25
Persian Fund	25,694.71	

BOSTON AND NEW ENGLAND.

SMALLPOX IN PROVIDENCE.—Report from Providence states that on April 18 two cases of smallpox were discovered aboard the Fabre steamship *Roma*, which arrived in port on that day from the Mediterranean. The first case had developed when the ship was nine days out from Marseilles. All the passengers were vaccinated and the patients were detained in quarantine.

MEETING OF CHARITABLE IRISH SOCIETY.—At a regular monthly meeting of the Charitable Irish Society on April 20, addresses were made by Dr. Allan J. McLaughlin, health commissioner of Massachusetts; by Dr. Timothy F. Murphy, who spoke particularly of tuberculosis; and by Dr. Thomas F. Harrington, director of hygiene in the Boston public schools, on preventive medicine in education.

HOSPITAL BEQUEST.—The will of the late James J. Myers of Cambridge, Mass., who died on April 13, was recently filed at the East Cambridge Probate Court. It contains a bequest of \$3000 to the Cambridge Hospital.

NEW HEALTH OFFICER.—Dr. Frank L. Morse, of Somerville, appointed to the position of district health officer, as noted in a recent issue of the JOURNAL, has resigned from that office because of other duties. Dr. McLaughlin has appointed Dr. Lewis Fish of Fitchburg to fill this position.

MASSACHUSETTS HOMEOPATHIC MEDICAL SOCIETY.—The annual meeting of the Massachusetts Homeopathic Medical Society was held in Boston on April 12, 13 and 14, in observance of the 75th anniversary of the foundation of the society. At the closing session Dr. G. Forrest Martin of Lowell, Mass., was elected president for the ensuing year. It was voted by the Society to send a contribution of \$500 to a medical field hospital which has been established by homeopathic physicians at Nenilly, France.

CASES OF INFECTIOUS DISEASES reported to the Boston Board of Health for the week ending April 20, 1915: Diphtheria, 34, of which 3 were non-resident; scarlatina, 84, of which 13 were non-resident; typhoid fever, 2; measles, 222, of which 3 were non-resident; tuberculosis, 44. The death-rate of the reported deaths for the week was 18.72.

INSTRUCTIVE DISTRICT NURSING ASSOCIATION.—A monthly meeting of the Boston Instructive District Nursing Association was held in this city on April 15. During the month of March 200 more new patients were treated than in February and 2000 more visits were made to patients in their homes. Four extra nurses have been needed to administer this increased amount of service. The twenty-ninth annual report of the Association, recently published, describes the work of the year and presents a study of 13,112 patients, showing the distribution of the fees, the details of the work, and the particular problems of different locality as regards tuberculosis, baby hygiene and unemployment.

MASSACHUSETTS HEALTH CONFERENCE.—Under the joint auspices of the Massachusetts Association of Boards of Health and the Massachusetts Health Commission there is to be held in Boston today an important public health conference under the chairmanship of Dr. Milton J. Rosenau, president of the Association. Invitations have been extended to health officials, publicists and charitable workers throughout the state, and there are to be addresses by President Eliot, Dr. W. T. Sedgwick, president of the American Public Health Association, Dr. Allan J. McLaughlin, Massachusetts Health Commissioner, and Professor Irving Fisher of Yale.

"The Massachusetts Association of Boards of Health is composed of health officials and persons interested in preventive medicine. It was organized in 1890 and meets four times a year. It was the regular meeting of this Association that was selected for the health conference. The objects of the Association meetings are the advancement of sanitary science in the Commonwealth of Massachusetts, the promotion of better organization of local boards of health, and the uniform enforcement of laws and regulations relating to the preservation and promotion of health. The meetings give an opportunity, also, for local health officials to explain to the state department of health problems and the solution of problems before the department, thus promoting a better coöperation not only between neighboring communities but between the state's department of health and the local boards of health."

MASSACHUSETTS CLEAN MILK BILL.—On April 22 the Massachusetts Senate passed to be engrossed the clean milk bill, whose passage has been editorially advocated by the JOURNAL and by various public health, charitable, and educa-

tional organizations in Boston. Mr. George R. Bedinger, director of the Boston Milk and Baby Hygiene Association, has recently sent to every senator a circular letter in behalf of this bill, reading in part as follows:—

"It needs no investigation to bring us to the conclusion that our State Department of Health ought to have the legal authority on its own initiative to stop the sale of milk from filthy places by means of such a law as Senate bill No. 482, making it illegal to sell milk handled under unsanitary conditions and providing that no person shall be prosecuted until after he has had a warning notice.

"Legislation has been postponed from year to year on every conceivable pretext and we think it is high time something was actually accomplished.

"It should be remembered that this campaign has been carried on during the last five years as a result of two official investigations made in 1910 and 1911. That the amendment to investigate the subject for still another year is made for the purpose of killing the bill, is shown conclusively by the fact that the men who are advocating it have already during this session voted twice against a similar investigation."

On April 26 an open meeting for milk consumers was held in the evening at Huntington Hall, Boston, under the auspices of the committee on agriculture of the Chamber of Commerce.

"For over a year the Committee on Agriculture of the Boston Chamber of Commerce, in co-operation with the federal and state agencies, has been making a very thorough investigation of the production, transportation, inspection, grading and distributing of milk and cream in New England. It has held meetings and conferences with the farmers, dealers, railroad representatives, milk inspectors and health officials. The conditions pertaining to each phase of the industry have greatly changed in the last ten years. The committee has endeavored to ascertain just what the present conditions are in each phase, *i.e.* how, and where, milk and cream are produced, transported, inspected, graded and distributed; what they cost and what becomes of the difference in price paid by the consumer and the price paid to the producer. The committee expects to issue a report about June 1, which will enable the public to have correct information as to the present conditions, with certain practical recommendations that can be carried out for the benefit of all. The committee has interviewed many large buyers of milk and cream but, before it makes up its final report and recommendations, it wishes to hear from the general consuming public."

EPIZOOTIC OF FOOT AND MOUTH DISEASE.—It is stated on apparently good authority that since March 18, no new cases of foot and mouth disease have occurred in Massachusetts and none is known to exist in the state. Dr. Lester H. Howard, commissioner of the Massachusetts Bureau of

Animal Industry, is reported to have said that the movement of cattle within quarantine towns is now allowed by special permit.

"Such permits will be issued in the future where the circumstances are favorable. In the western and northwestern parts of the State, where the foot-and-mouth disease never appeared, the cattle movements are unrestricted, but in the infected area of the State the quarantine may have to remain for ninety days after the last place in the country to report any infection has been fumigated. Under Dr. Howard's policy of issuing permits this does not mean the enforcement of the strict quarantine regulations that have tied the hands of Massachusetts farmers for the last six months, as the farmers will be allowed to move their cattle in vehicles if they apply to the Cattle Commissioner for permits, subjecting their activity to the State regulations; but it is the Government's intention to keep its reins on all cattle movements for the present in order that the check can be applied instantly if there is an outbreak anywhere. While Dr. Howard concedes that it may be perfectly safe to throw everything open now, he says it is better to be cautious a little longer, lest there be an animal somewhere carrying the disease on the skin, ready to yield to it if the skin is bruised or the general health is broken down. With such possibilities Dr. Howard wishes to take no chances, and the Federal Government will take no chances, if it can be avoided within reason. Cattle will not be allowed to walk or run in the public streets within the quarantined zones, but may be transported under proper conditions. Nor will the Department of Animal Industry in Massachusetts allow the full repopulation of disinfected barns at once. Despite the disinfection some germs may have escaped and may become active when cows are put back into the stables. Therefore the number to be put in at first will be regulated."

From the date of the first outbreak, last November, up to the present time, the foot-and-mouth disease has resulted in the slaughter in Massachusetts of 2104 head of cattle, 5703 swine, 77 sheep and 11 goats. These 7895 animals had an appraised value of \$230,000, of which the United States Government will pay \$115,000 and the State of Massachusetts \$115,000. To meet this charge the Massachusetts Legislature has appropriated \$150,000. There are heavy losses to the farmers, however, that are not covered by that appropriation, and never will be paid.

Obituary.

SIR THOMAS SMITH CLOUSTON, M.D.

DR. SIR THOMAS SMITH CLOUSTON, who died on April 19, at Edinburgh, Scotland, was born in

Orkney in 1840. He received his education at Aberdeen and Edinburgh Universities, and subsequently settled in Edinburgh as a practitioner in psychiatry. He had served as president of the Medico-Psychological Association, the Medico-Chirurgical Society and the Royal College of Physicians of Scotland. He had also been superintendent of the Royal Cumberland and Westmoreland Asylums and was for many years editor of the *Journal of Medical Sciences*. He was the author of several books, among them "Clinical Lectures on Mental Diseases," "The Neuroses of Development," "An Asylum or Hospital House," "The Hygiene of Mind," and "Unsoundness of Mind." He was distinguished throughout Great Britain as an authority on mental diseases and had received the honor of knighthood in 1895. He is survived by one daughter and one son.

JAMES BRAINERD FIELD, M.D.

DR. JAMES BRAINERD FIELD died at his home in Lowell, April 15, of pneumonia, after an illness of six days. He was born in Athol, Mass., Feb. 16, 1859, and was educated at the Boston Latin School and at Harvard College, from which he was graduated in 1880. After graduating from the Harvard Medical School in 1884 he began practice in Lowell. He was a member of the staffs of the Lowell General and Lowell Corporation Hospitals and had for twenty years been treasurer of the Association of the Massachusetts Boards of Health, and for nine years chairman of the Lowell Board of Health.

He was a counselor of the Massachusetts Medical Society from 1907 to 1908, and president of the Middlesex North District Medical Society in 1912-13.

He is survived by his widow, one daughter, and a son, who is a student at the Harvard Medical School.

Miscellany.

DEFENCE OF ANIMAL EXPERIMENTATION IN BOSTON

IN the issue of the JOURNAL for April 15, we noted the recommendation initiated by Mayor Curley for the establishment of a fund of \$20,000 in the pathological department of the Boston City Hospital for the experimental study of scarlet fever, measles and other infections. This proposition has been opposed by anti-vivisectionists who have protested to the mayor against the project. In his reply to one of these protestants

Mr. Curley wrote as follows in defence of animal experimentation.

"Unfortunately, perhaps, for myself, I have adopted the policy through life of speaking plainly my mind with reference to any question submitted, and like all humans, it is only natural that from time to time I err and not infrequently make mistakes. In this case however, I believe that I am not committing an error, neither am I making a mistake, despite the fact that the action taken by me will result in the estrangement of those whom I have regarded as friends.

"The same condition that obtains at Boston is found throughout the entire United States and the world generally. The financial loss to the city during the past six years resulting from epidemics of scarlet fever and measles is not less than \$600,000. There is no method of logic by which it is possible to determine the injury or the suffering caused to parents through illness and death of their children. It is perfectly proper for the individual to have a high regard for pet animals, and while the chimpanzee is not attractive as a pet, I find it has numerous admirers.

"I firmly believe that the life of one child is of more value to its parents than all the chimpanzees in existence, and if, through vivisection of chimpanzees, a serum can be produced that will result in the saving of the lives of children, I am prepared to attempt the experiment regardless of whose sensibilities may be offended."

In approbation of this attitude on the subject of animal experimentation the following letter was sent to the mayor by Dr. Withington as president of the Massachusetts Medical Society.

"Dear Mr. Mayor—I beg leave to express to you in behalf of some three thousand physicians of this State, our profound appreciation of the strong letter which has appeared in the public press from your honor to an objector against animal experimentation as an aid to the saving of human life.

"In the midst of ignorant statements regarding the status of epidemic disease, which might be easily corrected by a reference to health statistics, and of assertions of the infliction of torture upon animals, which have been mercifully made oblivious by anaesthesia, it is refreshing to have a sane statement from a man and an official interested in the saving of human life and the stopping of economic waste. The vivisection (for every prick with a hypodermic needle is technically that) practised for years in our municipal laboratory in the testing of the virulence of diphtheria and other organisms, has already borne abundant fruit in the saving of many children's lives.

"Chimpanzee or child? Which is the better worth saving? You have answered the question courageously and it is to be hoped, definitely, and in so doing you deserve the thanks not only

of scientific workers, but of the fathers and mothers in the city.

"Yours respectfully,

"CHARLES F. WITHINGTON, M.D.

"President of The Mass. Medical Society."

The attitude of the mayor and its prompt recognition by the representative of the Massachusetts medical profession is a matter of encouragement and congratulation for the cause of animal experimentation.

TUBERCULOSIS "REMEDIES" THAT ARE WORTHLESS.

THE United States Department of Agriculture has recently issued the following statement about so-called tuberculosis cures:—

"After investigating under the Food and Drugs Act, a large number of preparations advertised as consumption cures, the Department of Agriculture has not been able to discover any that can in any sense be regarded as 'cures' for tuberculosis. Some contain drugs that may at times afford some temporary relief from the distressing symptoms of the disease, but this is all. Since the passage of federal legislation prohibiting the shipment in interstate commerce of medicinal preparations for which false and fraudulent claims are made, there has been a marked tendency to label these preparations 'remedies' instead of 'cures' or 'infallible cures,' as they used to be called. In many cases, however, they cannot even be regarded as remedies.

"A 'cherry balsam,' for example, for the 'cure' of 'consumption' and 'hemorrhage of the lungs,' which it was represented would 'strike at the very root of the disease,' was found on analysis to be nothing but a solution in water and alcohol of opium, sugar, benzaldehyde, inorganic salts and coloring matter. It contained no cherry bark extract or balsam.

"A more elaborate 'cure' consisted of five different preparations which the credulous patient was to take separately. These were: first, the medicine proper, the essential ingredients of which were found to be morphine, cinnamic acid and arsenic—not a very safe mixture to take habitually; second, a tonic which was supposed to contain iron but did not; third, a 'cough mixture,' made up of alcohol, chloroform, and codeine; fourth, a mixture which contained some quinine, and a solution of water and alcohol; and fifth, codeine tablets. Even the strongest constitution could hardly stand a prolonged course of such a treatment.

"In the marketing of such preparations considerable ingenuity is frequently shown. One of the main objects is to persuade the patient that he is receiving, at a comparatively low price,

the individual attention of a trained specialist. For this purpose, symptom blanks are employed. These contain a number of questions about the patient's symptoms, the number varying from a dozen or so to as many as seventy or eighty. The patient is led to believe that the information which he furnishes in reply to these questions, will be carefully considered before any medicine is prescribed for him, though every physician knows that an accurate diagnosis cannot possibly be made in this way. As a matter of fact, none is attempted, and the degree of attention which these individual reports receive can be measured by the fact that cases have come under the observation of the department in which mail order concerns doing a business of this kind have received as many as 4000 letters a day.

"After the patient has submitted his 'diagnosis report,' he is urged to purchase a supply of the medicine. If he does so, he is then urged to purchase more. If he states that he has experienced no beneficial effects he is told that he has not taken enough, and this process is likely to continue until the limits of his credulity have been reached. If, on the other hand, he decides at the beginning not to purchase the medicine, it is likely to be offered to him at successively lower prices until he is at last induced to believe that he cannot afford to ignore such a bargain. This is carried to such an extent that a 'treatment,' the original price of which is \$25, may be offered at the end of six months for \$2.50.

"As a matter of fact, the successful treatment of tuberculosis requires much more than the mere giving of medicine and, moreover, what will help one case will not necessarily help another. Claims that are absolutely unwarranted are no longer permitted on the labels of medicines shipped in interstate commerce, but the wording may be such as to convey a misleading impression without the use of absolute statements. Thus these preparations continue to find a sale, despite the fact that a little trouble on the part of the prospective purchaser will reveal their worthlessness."

AMERICAN SOCIAL HYGIENE ASSOCIATION.

THE American Social Hygiene Association has recently announced the offer by one of the large insurance companies of a prize of \$1000, to be awarded to the author for the best original pamphlet on social hygiene for adolescents between the ages of twelve and sixteen. The competition for this prize is open to all, and typewritten manuscripts, not exceeding 3500 words in length and signed by a fictitious name, must be submitted, with the author's true name in a sealed envelope, to the American Social Hygiene Association, 105 West Fortieth Street, New York

City, not later than July 31, 1915. The following statement with reference to the competition was published in the bulletin of the Association for March, 1915:—

"In offering a prize of one thousand dollars for a social hygiene pamphlet for adolescents, suggested and generously provided by the Metropolitan Life Insurance Company, the American Social Hygiene Association is presenting a problem for solution by writers in the social hygiene field. The conditions under which this offer is made are printed elsewhere in this number of the Bulletin. No suggestions or restrictions as to methods of presentation or treatment of the subject-matter are made. It is, perhaps, unnecessary to say that accuracy of statement, such use of statistics and quotations as is warranted by the context from which they are taken, broad and practical grasp of the subject as presented, soundness of pedagogical method, and attractive and convincing form are among the important points to be considered in judging the merits of manuscripts submitted.

"The questions most frequently asked by those interested in the competition are: 'What kind of pamphlet is wanted? Is it to be written for boys, or for girls, or for both—or for parents? Must it cover the entire period of the four years specified? Must it take up the physiological changes of adolescence? What sort of instruction may the author assume that the child has had before reading the pamphlet?' To such inquiries the reply is that the prize has been offered for the best solution of the problem of approaching through the printed word the youth of America from twelve to sixteen years of age. If the author is convinced that the indirect approach through the parent is the proper method, he may prepare his manuscript for use by the parent. If he thinks that the most pressing need is for a pamphlet to be placed in the hands of boys, he may prepare his manuscript for that purpose. Similarly, he may prepare it for the use of girls, or, if he thinks it more desirable, he may combine his information into a single pamphlet for the use of both boys and girls. If he believes that adolescents from twelve to sixteen years of age do not form a practical group, he may direct his effort toward any portion of this age group (for example, those from twelve to fourteen years, or those from fourteen to sixteen years), and may so indicate. He may submit his manuscript as one of a series designed for special groups, but should present also the other numbers of the series, to show its character as a whole. Notes explaining the points of view from which it has been prepared may be submitted with the manuscript, bearing the same identifying mark or pen-name, but not the name of the author.

"It is generally recognized that the early adolescent period in the life of both boys and girls presents one of the most difficult problems in educational work. In the special fields of instruction or education with which the social

hygiene movement deals, this period is probably the most difficult. There is substantial agreement as to what information ought to be given the young child and as to the desirability of thorough, scientific instruction touching on the problems of sex and reproduction for persons of mature years. But the problem of the early adolescent period still awaits a satisfactory solution."

GERMAN MEDICAL EFFICIENCY.

A Swiss correspondent in a recent issue of the *Lancet* describes a recent visit made by a party of Italian and Swiss Red Cross physicians to German military hospitals along the western battle front, and at Berlin, Brussels, St. Quentin and Sedan. Professor Baldo Rossi speaks with enthusiasm of the efficiency of the German army medical service as witnessed on this occasion.

"The organization of the German medical service is simply wonderful. Nothing seems to have been left to chance, but, on the contrary, every detail seems to have been thought out carefully. At Berlin a large number of public and private buildings — theatres, cinematograph houses, police stations—have been handed over to the Army Medical Department, while various types of hospitals are situated at different points along the main roads which link up the capital to the fighting line. The wounded are not removed from the trenches until evening, as there is the danger of transports being attacked in the daytime by the enemy. Medical assistance is, of course, rendered immediately, and the German trenches, moreover, are not uncomfortable places. At dusk ambulances drawn by horses reach the trenches and the wounded are transferred into them. Horse ambulances are used because the roads are frequently too difficult for automobiles, and because, even were the latter used, the noise of the motors and the glare of the headlights would attract the enemy. The wounded are first taken to the medical stations situated about five miles in the rear of the trenches, each of which is under the supervision of nine doctors, of whom three are surgeons and one an oculist. These medical stations have been carefully selected and contain operating tables, instruments of the most expensive and intricate kinds, and all drugs that might be required. Many of the beds in use are curious, and offer testimony to the practical nature of the Germans. The number of wounded proved so much greater than had been anticipated that the ambulance men were compelled to make beds to the number of many thousands from the boxes and cases which had contained food for the troops."

Of the nature of the wounds and their treatment Dr. Rossi speaks as follows:—

"Most of them are caused by cannon projectiles, whereas in preceding wars injuries were

mainly due to rifle fire. Wounds in the head are numerous, owing to the trench fighting, which is the chief characteristic of the campaign. Instances of 'frozen feet' are not frequent, one reason being that the German soldiers wear very high boots. Amputation, practised so largely in previous wars, is now reserved by the Germans for desperate cases, so that at the end of the present war, vast and terrible though it is, mutilated men will not be very numerous."

At Brussels the visitors attended a conference of German medical officers for the discussion of the public health problems of Belgium and the efficient reorganization and administration of local public hygiene and sanitation.

SOME ANTI-VACCINATION ARGUMENTS.

At a recent meeting of the American Anti-vaccination League in favor of the bill (House No. 886) then pending before the Massachusetts General Court, but since fortunately defeated, the following statements were made by some of those present in opposition to vaccination. These statements seem of interest as examples of the type of argument against which the medical profession must contend in its effort to maintain the advancement of science for the benefit of the public.

"I object to the practice of vaccination because it does not, in my belief, act as an effective preventive. The insistence upon revaccination tends to corroborate this doubt. But waiving the question of degree of protection afforded by vaccination, and assuming it to be relatively innocuous, I protest vigorously against the invasion of individual rights caused by the official operation of a compulsory law.

"Some superstitions die hard, and I can only say to the compulsory vaccinators that I shall welcome the general injection of vaccine only when they succeed in procuring it from the cow that jumped over the moon."

"The meeting was called in the hope of strengthening our forces against our enemy. Our enemy in the present instance is medical tyranny, the tyranny of the political doctor, the members of the American Medical Association, which is the greatest menace this country has today. We are here to protest against the compulsory poisoning of the blood stream of our healthy children in the absurd hope of protecting them against some disease in the future to which there is every reason to believe they will never be exposed.

"If Massachusetts through an unjust law, passed many years ago in ignorance, or through undue influence of a privileged class, has caused the death or life-long injury of one single child, isn't that sufficient reason for the repeal of the compulsory vaccination law? After sixty years of compulsory vaccination, the number of chil-

dren killed or permanently injured is well up in the thousands.

"For years past over two-thirds of all those who have succumbed to smallpox had been vaccinated. Where there is most vaccination there also is most smallpox; where there is least vaccination and good sanitation, there is the least smallpox, and the lowest general death-rate."

MEMORIAL RESOLUTIONS.

HENRY WALTON WOOD, M.D.

At a meeting of the Boston Society of Psychiatry and Neurology held April 15, 1915, the following memorial was read:—

By the death of Dr. Henry Walton Wood the Boston Society of Psychiatry and Neurology loses one of its younger members. Through his personality and capacity he had already established an enviable position for himself in the general practice of medicine. His previous training and natural inclination, however, led him into the special study of psychiatry, a field in which his preliminary work gave promise of substantial accomplishment. His opinion on matters relating to the nervous system was increasingly sought by his colleagues and by the courts.

The Boston Society of Psychiatry and Neurology desires to express to his widow and family its sympathy at his untimely death and to cause this tribute to his memory to be spread upon its records and to be published in the BOSTON MEDICAL AND SURGICAL JOURNAL.

J. W. COURTNEY, M.D.

E. W. TAYLOR, M.D.

F. P. SIMPSON, M.D., *Treasurer*,
7048 Jenkins Arcade Bldg.,
Pittsburg, Pa.

The following letter from the Pittsburg branch of Messrs. Marwick, Mitchell, Peat & Company has just reached the hands of the Treasurer.

PITTSBURG, PA., March 26, 1915.

DR. FRANKLIN H. MARTIN, *Chairman*,
Committee of American Physicians for
the Aid of the Belgian Profession,
Chicago, Ill.

Dear Sir:

We have audited the accounts of the "Committee of American Physicians for the Aid of the Belgian Profession" for the quarter ended March 20, 1915.

WE HEREBY CERTIFY that all donations received have been properly accounted for and applied to the purchase of provisions and that the following is a correct summary of the Receipts and Disbursements for the period:

Receipts \$5221.50

Disbursements:

1625 boxes of food 3575.00

Balance on deposit in Union

Trust Company, Pittsburg, Pa. \$1646.50

All but nine of the boxes of food had been delivered at the Bush Terminal, South Brooklyn, New York, to "The Commission for Relief in Belgium" as at the date of our audit, and in addition 715 boxes have been ordered, bringing the total of the boxes up to 2340. The foregoing bank balance will be used to pay for the 715 boxes on order.

Yours truly,

(Signed) MARWICK, MITCHELL, PEAT & CO.

AID FOR BELGIAN PHYSICIANS.

It has been difficult to get definite information regarding the exact destination of food and supply boxes sent into Belgium. A recent letter from Dr. S. Squire Spriggs, Hon. Sec'y of the Relief Fund for Belgian Doctors and Pharmacists, gives the following information:

"The boxes of drugs, instruments, and dressings duly reached Brussels and were there distributed to the place where they were most needed by the Aide et Protection aux Médecins et Pharmaciens."

The latter is a Committee of Belgians formed to consider the condition of the doctors and pharmacists. It is a representative body and has organized machinery for ascertaining where the need is greatest among those whom it would help and providing sys-

tematic relief. Forms have been issued to all the doctors and pharmacists in Belgium on which they are asked to state frankly their positions and that of their families, the loss they have sustained and the estimated amount of money to enable them to tide over their existing terrible circumstances. On these points the Committee has acted in consultation with the local medical societies throughout Belgium and with the Government Inspectors of Pharmacy. Small amounts of money have been distributed in this way and the better circumstanced doctors and pharmacists of the larger cities of Belgium have contributed to this fund. Originally this Committee had a subsidy from the National Relief Fund but this is now exhausted. The British Committee have investigated this work and are advising now that help in money should be sent.

DR. J. RIDDLE GOFFE,
New York.

RED CROSS RELIEF.

The American Red Cross shipped to England on the American liner *St. Paul* on April 24, a \$10,000 consignment of hospital and medical supplies to the British Red Cross. The consignment included 11,000 pounds of absorbent cotton, tetanus antitoxin, and thousands of hospital garments. On the Russian-American liner *Kursk*, which sailed on April 27, the Red Cross shipped a \$21,000 consignment to the Russian Red Cross at Petrograd. The consignment consisted of hospital garments, hospital supplies and miscellaneous clothing.

On the Italian liner *San Giovanni*, which sailed on April 24, the Red Cross made its first shipment to the Montenegrin Red Cross at Cetinje. The consignment included 1100 pounds of absorbent cotton, a large quantity of hospital supplies, and clothing for destitute women and children.

The first shipment of comfort kits for the convalescent soldiers of France was sent on April 24 on the French line steamship *Rochambeau*. There will be some 2000 of these kits forwarded by the Lafayette fund, which has been engaged during the past winter in sending kits to the French soldiers in the trenches.

APPOINTMENTS.

Dr. Charles P. Bancroft of Concord, N. H., was, on April 15, reappointed superintendent of the New Hampshire State Hospital.

Dr. Edmund Winfred Wilson was, on April 16, appointed assistant superintendent of the Boston City Hospital.

On April 19 the corporation of Yale University appointed *Dr. Charles Edward Amory Winslow* of Boston as professor of public health in the Yale Medical School on the Anna M. R. Lauder Foundation. Dr. Winslow has served as assistant health officer of Montclair, N. J., as member of the Massachusetts State Board of Health, as assistant professor of sanitary biology at the Massachusetts Institute of Technology, as associate professor of biology in the College of the City of New York and as head of the division of publicity and education of the New York State Department of Public Health.

Dr. Harold B. Myers of Portland, Me., has been appointed professor of materia medica and pharmacology and *Dr. Howard D. Haskins* of Cleveland, professor of physiologic chemistry at the University of Oregon.

Dr. H. Roy Dean, who since 1912 has been professor of pathology at the University of Sheffield, England, has been appointed professor of pathology and pathological anatomy at the University of Manchester.

CENSORS' EXAMINATION.

The Censors of the Suffolk District Medical Society will meet to examine candidates for admission to The Massachusetts Medical Society at 8 The Fenway, on Thursday, May 13, 1915, at 2 P.M.

Candidates, who must be residents of the Suffolk District, or non-residents of Massachusetts, should make personal application to the Secretary, and present their medical diplomas, at least three days before the examination.

For further particulars, apply between 2 and 3 P.M. to

WALTER C. HOWE, M.D., *Secretary*,
303 Beacon Street.

SOCIETY NOTICE.

NEW ENGLAND PEDIATRIC SOCIETY.—The thirty-eighth meeting of the New England Pediatric Society will be held in the Boston Medical Library, Friday, April 30, 1915, at 8.15 P.M.

The following papers will be read:

1. "Can the Speech Present a Sign of Congenital Syphilis?" W. B. Swift, M.D., Boston.
2. "Acute Otitis Media in Childhood; Avoidable Mistakes in Diagnosis, Prevention, Treatment." W. R. P. Emerson, M.D., Boston.
3. "Studies in Bronchial Glands." W. W. Howell, M.D., Boston.
4. "Endocarditis in Children; Its Prophylaxis and Treatment in an Out-Patient Department." R. S. Eustis, M.D., Boston.

Light refreshments will be served after the meeting.

E. M. BUCKINGHAM, M.D., *President*.
RICHARD M. SMITH, M.D., *Secretary*.

RECENT DEATH.

DR. A. A. W. HUBRECHT, professor of embryology at the University of Utrecht, Netherlands, died on March 21 at the age of 63 years.

BOOKS AND PAMPHLETS RECEIVED.

General Index to the Annals of Surgery. Vols. 51 to 60, 1910-1914.

Address

THE TUBERCULOSIS WORK IN CONNECTICUT, ITS DEVELOPMENT IN THE LAST DECADE, AND ITS FUTURE NEEDS.*

BY DAVID RUSSELL LYMAN, M.D., WALLINGFORD, CONN.

TEN years ago a paper on the subject I have chosen would have had very little to say about past accomplishments and a great deal concerning the future. At that time the work was generally considered by most people to be in the experimental stage. We sent our dying patients far away from home in the hope that a change of climate would accomplish the impossible—and we carefully refrained from telling the early cases that they had tuberculosis for fear that the shock would destroy their chance of recovery. For those who had not as yet contracted the disease, but were in constant contact with it in its worst forms, we did nothing at all. In 1902, however, a small body of men, furthering a movement inaugurated by the New Haven County Medical Society, formed and incorporated the New Haven County Anti-Tuberculosis Association, and through their efforts the Gaylord Farm Sanatorium was opened in September, 1904, with a capacity of 22 beds.

Today Gaylord Farm has 110 beds: Wildwood, at Hartford, 50; the four state sanatoria at Hartford, Meriden, Norwich and Shelton a total of 600; and the New Haven Hospital is pre-

paring to build for 110 more. Stamford and Greenwich also maintain small wards with a total of 30 beds. These, with the available room in private institutions, give us about 950 beds. The great Commonwealth of Massachusetts has less than 2000; and, in fact, no state can, in proportion to population and resources, show so liberal a provision for the treatment of her tuberculous cases.

Ten years ago there was but one association devoted to this work—the New Haven County Anti-Tuberculosis Association. Now there are similar organizations in Waterbury, Meriden, Hartford, New Britain, Middletown, Norwich, Norwalk, South Manchester, and Stamford.

Then there was not a single tuberculosis nurse. Now New Haven, Waterbury, Meriden and New Britain have them, and the Visiting Nurses' Associations of other cities make special provision for tuberculosis work.

Then there were no tuberculosis dispensaries. Now these are found in New Haven, Hartford, Waterbury and Norwalk, and one is being organized in Meriden.

There were no associations for providing relief for the tuberculous workman or his family. The Employees Relief Association movement has been developed in Hartford, New Britain, South Manchester, New Haven and Bridgeport. This work comes closer to the solution of the problem of financing a long period of treatment for the workman than any other agency, and is probably Connecticut's greatest contribution to the general tuberculosis campaign.

More and more attention is being paid to the open air schools for tuberculous, backward or

* Read before The New Haven County Public Health Association.

defective children. We now have these in Hartford, New Haven, Waterbury and South Manchester, as well as in the children's pavilion in Gaylord Farm, and at the State Sanatorium at Hartford.

In addition to the above we have the State Tuberculosis Commission, established for the purpose of directing the work of the state sanatoria, and carrying on the general campaign throughout the state. Under the present interpretation of the statutes, the commission is without funds to do all the work of a central state agency, which it should do, and for which it is otherwise fairly well equipped. We hope the coming legislature will remedy this defect in the statutes, and permit the State Commission to take up that work which is so eminently its main task and the reason for its existence.

Looking back over the past decade we see a remarkable growth from the small beginning made by the New Haven County Association. We have a right to be pleased with our progress, but there is still much to be done. True, our death-rate is showing a most satisfactory drop; but the state statistics for 1913 still gave a total of 1659 deaths from all forms of tuberculosis. My experience of the past ten years would make me look askance at the 539 deaths reported from "bronchitis," "grippe" and "pleurisy." But leaving these out of consideration and accepting the customary average of ten cases for every death, we see that we have at present between 16,000 and 17,000 cases of tuberculosis in our state. With the vast amount of work yet to be done, the question of how to direct our energies in the next few years becomes a most pertinent one. How must our present works be modified or extended and what new lines of endeavor must be considered?

Our most efficient agencies so far have been the sanatoria for curable cases, the infirmaries for advanced ones, and the dispensaries, with their attendant tuberculosis nurses, to work among the people in their homes.

SANATORIA.

I am convinced that for the present there is no need for the state to erect more sanatoria for curable adult cases. There is practically never a time when we cannot find room for a good early case in one or the other of our sanatoria. Until there has been a further advance in the early diagnosis of the disease, our work so far as regards institutions for early cases, must be to increase their efficiency rather than their capacity.

To this end, the one crying need is for some provision for the care of the immoral, drunken, or unruly cases that are sent to these sanatoria by the departments of charity of our cities and towns.

The value of a sanatorium is twofold. It should restore the patient's health and at the same time teach him, not only how to retain his

working capacity, but after his return how to do his share in teaching the general public how the spread of tuberculosis can be prevented. To do these things, it is essential that the sanatoria, like any other school, should have a certain regimen and discipline, so that the patient and the public at large may get the most benefit from the large expenditures the state is making on this work. There are, unfortunately, quite a large number of cases that, whether through an adverse environment, lack of moral courage, or other causes, have degenerated to where they have lost sight of their obligations to their fellow men. Their one consideration is to do as they please. They are not only willing, but anxious, to stay in the sanatoria, where the accommodations, food, etc., are the most comfortable they have known. They are not, however, willing in order to enjoy these advantages to conduct themselves with any consideration of the sanatorium, their fellow patients, or their own physical needs. They wish to be allowed to get drunk as often as they can, to leave the place when they please, and return at any and all hours; and when they express displeasure or dissatisfaction, expect the nurses and other patients to make no objection to whatever vile and filthy epithets they may prefer to apply to them. The presence of these cases made it impossible to get the decent, self-respecting people, however great their need of treatment, to go to the sanatoria. Realizing that the sanatoria could never be more than mere lodging houses under these conditions, the State Commission began over a year ago to discharge all such cases that, after full trial and repeated warning, failed to comply with the most important of the rules. The statutes are specific in their mandate that we shall not receive or retain such cases unless separate provision is made for them, and we have no such separate accommodations, no funds to provide them, and no police authority to control them.

The statutes, however, also provide that such cases must not be kept in the almshouses, but must be sent to special tuberculosis hospitals. The situation today is, therefore, as follows: There are a large number of ignorant, immoral, and often vicious consumptives, whom the sanatoria are forbidden to take, and who cannot be put in the almshouse. Their presence in the poorer tenements of our cities is a great menace. The coming legislature must provide for their care, and it seems that this must be done in one of two ways. Their treatment in the sanatoria is impossible. Either a separate institution must be created by the state and maintained for these cases, or the cities and towns must be permitted to care for them in separate accommodations in connection with the almshouses.

The chief objections to the state furnishing the institution, are the expense, the difficulty of securing a site for an institution of this character, and the impossibility of maintaining it on the large scale that would be necessary unless it

were put on the grounds of some other institution already under police control, or unless the commission were given police authority over it. There would also be this great objection to a single institution: It must of necessity be distant from most of our cities, and although derelicts of humanity, its inmates would at one time of the year have an equal value with any of us, for we are all allowed but one vote. There would, therefore, be all sorts of pressure brought to bear to keep these votes where they would be readily available. It seems to be the consensus of opinion of the town authorities that a state institution would be best; but these opinions are based chiefly on the consideration of the expense to the small towns of maintaining their own institutions. We can, however, see no reason why the counties could not maintain such a place for the small towns and the large cities maintain their own. These buildings should be subject to the approval of the state commission, but not under its control. These town or county pavilions should be permitted to take only those cases that have proven unsuitable for treatment at the sanatorium. Instead of, as at present, the towns paying \$4.00 a week and the state \$7.00 to provide for these cases, the state should pay a weekly per capita to the towns for all cases in their pavilions. This plan could, I am sure, be worked out so as to care for these unfortunates in an adequate manner and at a financial saving both to the towns and to the state. The general public would be free from the menace of their unrestrained presence and the sanatoria would be developed to their greatest usefulness.

ADVANCED CASES.

The state accommodations for advanced cases are as yet inadequate. There is never a time when there are not many cases requiring infirm care waiting for admission; and now that the opening of our new infirmary at Shelton has made accommodations there what they should be, the number of applications is constantly increasing. The present building is but the central portion of the one we hope in the next year to be permitted to complete, and which, when finished, will give us sixty more beds for these cases. The 110 beds in the projected plant of the New Haven Hospital at Allingtown will also be devoted to advanced cases; and when both the above are in operation our accommodations will be fairly adequate.

CHILDREN.

Up to the present time the work among the children has been almost neglected. Gaylord Farm and the State Sanatorium at Hartford have separate quarters for them, where they can be segregated from the grown patients, and in both places a school is maintained. The number of beds available is, however, woefully inadequate. The State Commission recently sent an

inquiry to every teacher in the state in order to find out how many children there were in our schools, public and private, who had probable tuberculosis of the bones, glands or joints. From the answers received it would appear that there are at present in our schools about 4000 such cases. The value of seaside sanatoria for these cases has been proven beyond question. We hope that it will not be long before somewhere on our long expanse of beach we will see provision made for at least some of these little patients. These are the ones who if neglected now will fill our sanatoria with active cases in later life, and we can surely never control tuberculosis until we care for them.

The open air school movement should also be extended in all our cities. Many of the weakly anemic, backward children, many in the pre-tubercular stage, as it is often called, will not only acquire a sound basis of health under the influence of these schools, but will at the same time keep up in their studies—a feat that is utterly beyond their strength in the general classroom.

DISPENSARIES AND VISITING NURSES.

We cannot hope to cope with the 17,000 existing cases in our state if we depend solely or even chiefly upon institutions for their treatment. All important as is the treatment of the early cases, our hope of some day controlling tuberculosis is based on our knowledge that it is a preventable disease. To prevent it, however, it is essential that the people be taught. The press, the public lectures, and the warning and instructive placards in public buildings and factories all have a great value in this work; but to teach effectively you must teach the individual and must do it personally. It is for this reason that I rate the special dispensary, with its visiting tuberculosis nurse as the most valuable of all our forces in the campaign. The early diagnosis of tuberculosis is most difficult, but it is not nearly so difficult as it often is to make the patient accept the diagnosis and institute proper treatment. The chances are that he will be utterly unable to believe that the slight symptoms he has mean "consumption"; that he will go around to several other physicians; and if only one of the number expresses doubt of his being so afflicted the patient will decide that he is well, and postpone going away or taking any precautions until it is too late. The visiting nurse, however, follows up the patient, visits him at his home; spends hours if need be explaining, arguing, persuading; convinces other members of the household and secures their aid, brings up acquaintances to testify of their own experiences, and usually prevails upon the patient to take the treatment. But this is only a small part of the nurse's work. She goes to the home, where the danger of infection exists. She shows the people right on the premises how to carry out the necessary precautions, how to

clean up the room and let in light and air, what to do with dishes, sputum, etc., and she goes back again and again to see that these things are done and done correctly. Often it is impossible for the patient to go away for treatment, and then the nurse must arrange the patient's daily life, supply food and clothing, and day after day, and week after week, go back to encourage, advise and direct, not only the patient, but the whole household. In houses where there has been exposure from a chronic case, she can often detect suspicious symptoms in other members, and by getting them to a doctor for examination can get the diagnosis before the disease has begun to make headway.

The visiting nurse has another and a very important duty. We are recognizing more and more the value of proper after-care of our discharged patients, and are slowly realizing how much can be done by follow-up work toward making our so-called cures permanent. It is human nature to be on one's best behaviour when we know someone is watching. When the visiting nurse has a record of the discharged cases returning to town, and these patients know that she will visit them and inquire as to their daily routine, they are going to be more careful as to what they have to report. More than this, the nurse can discover, and often do away with, adverse conditions either in the home or in the place of employment, and can see that the patient goes to his physician at frequent intervals for examination and advice. Her coöperation after the patient goes back home and to work is not the least valuable of her many good works.

Given a dispensary where physicians trained in the diagnosis and treatment of tuberculosis can see the patient at intervals and direct the course to be followed; a visiting nurse to go to the home, instruct the family there, see that the patient follows orders, and bring any suspects to the dispensary for diagnosis; and behind these two a local association to furnish funds for treatment at home or in an institution, and we have the most valuable development of all our tuberculosis work.

The State Board of Health report for 1913 furnishes statistical evidence of the truth of this. The four largest counties in the state are New Haven, Hartford, Fairfield and New London. Almost all of the visiting nurses, dispensaries, and local associations are in New Haven and Hartford counties. Fairfield has none outside of Stamford, and New London none at all. Since 1907, the time when the work was begun, the records for these counties is as follows:—

New Haven, pop. incr. 311—357,000; death decr. 488 to 441 rate decr.
Hartford, pop. incr. 229—266,000; death decr. 324 to 309 rate decr.
Fairfield, pop. incr. 208—263,000; death incr. 358 to 369 rate decr.
New London, pop. incr. 87—93,000; death incr. 123 to 126 rate incr.

These figures would indicate that there was some agency at work in New Haven and Hartford counties that was not present in the other two, and the agency is to my mind the work of the local associations and their visiting nurse.

I feel very strongly that this is the work which we must strive to extend throughout the state if we would ever hope to control tuberculosis; and I feel that the future efforts of the state itself must be directed along this line, rather than toward the erection of more sanatoria, once the children have been cared for.

In taking over the state agency for the Christmas seals this year, the State Tuberculosis Commission had chiefly in mind the opportunity it afforded for getting in touch with the people throughout the state and aiding in the establishment of local tuberculosis associations wherever possible. We hope in time to see it develop to where the local associations will be able to devote all their funds to local relief work, and will be supplied by the state with visiting nurses to look after their tuberculosis cases, and to teach the prevention of tuberculosis where it should be taught—in the homes of the people. This plan would not entail a great expense upon the state and it would increase enormously the funds available for local relief work in the cities and towns. Suppose, for instance, the salaries of the three tuberculosis nurses of New Haven were paid by the state and the amount this requires released for relief work, can you not see how the latter could be extended? It would be a long step toward the solution of the problem of providing funds to keep tuberculous patients under treatment long enough to secure lasting results. We also hope in coöperation with the physicians of the state, to have the nurses' work supplemented by the establishment of dispensaries for the tuberculous poor, where the nurses and their patients can have the advantage of the advice of both the physicians of their towns and of men with special tuberculosis training, supplied from the medical staffs of the state sanatoria. When we have this local work established and supplemented by the generous provision the state is making in our sanatoria, we feel that we will be combating tuberculosis in the right place, at the right time, and in the right way.

Original Articles.

A RARE TYPE OF BLADDER ULCER IN WOMEN; REPORT OF CASES.*

By GUY L. HUNNER, M.D., BALTIMORE, MD.

AFTER a review of the literature on simple ulcer of the bladder I wish to present for your consideration this evening a group of cases in

* Read at a meeting of the New England Branch of the American Urological Association held in Boston on November 30, 1914.

which the lesion differs in many respects from the so-called Fenwick ulcer which has been the type heretofore designated as simple ulcer.

This group presents a strikingly uniform picture, an appreciation of the features of which by our branch of the profession will save the patient from much suffering, both from errors in diagnosis and consequent futile operations on other organs, and from the unnecessary prolongation of ordinary cystitis treatment when more radical measures are demanded.

These ulcers have been found in women, my work being confined to that sex. They probably occur in men. The average age of the eight women on first consultation was thirty-seven years, but the average duration of the bladder symptoms was seventeen years, making twenty years the average age at onset. Two cases stated that they had had bladder trouble as long as they could remember. In striking the average for the group I arbitrarily placed their onset age at fifteen years or about the menarche.

In none of the histories could I determine cause for the bladder lesion.

Three of the patients were unmarried, and there was no reason from the history or examination to suspect a former gonorrheal cystitis. Of the five married women, all had borne children, but in three of them the bladder trouble antedated childbearing and in the other two the bladder symptoms came on, in one, eleven years, and in the other one year after the last childbirth; so we cannot ascribe their trouble to puerperal infection. In no case was there a history of operation or catheterization to give an opportunity for possible traumatic or infectious origin from such sources.

If we accept the usual view that either an embolus or a thrombosis of a blood vessel is immediately responsible for simple ulcer of the bladder and cast about for the distant focus of infection in these cases, we find very little of even suggestive importance.

With the possible exception of Case IV, who gave a history of indefinite bladder symptoms since scarlet fever at six years of age, and who later recalled that for weeks after peritonitis (appendicitis) at twelve years of age, she suffered intensely on voiding, none of the cases gave a history of acute infectious fever immediately preceding their bladder symptoms.

CASE 1 had her bladder symptoms exaggerated when she caught cold, but there is nothing said in her history about tonsil or sinus infection.

CASE 2 had complained of rheumatism for several years and has had occasional attacks of rheumatism while under my care for the past six years, but I have been unable to find a source of origin.

CASE 3 had an attack of tonsillitis twenty years ago, but has had no throat trouble since, and she had been treated for bladder trouble before the tonsillitis attack.

CASE 4, as noted, may possibly have followed scarlet fever or an acute appendicitis attack.

CASE 5 never had evidence of tonsil or sinus

trouble, but had had rheumatism of the left knee intermittently for three years. Her bladder symptoms antedated this by three years.

CASE 6 had scarlet fever as a child and had nocturnal enuresis up to the menarche at fourteen years of age. Her severe bladder spasms began six months after the first menstruation.

CASE 7 had never had tonsillitis. As a child she had measles, mumps, and whooping-cough. Her bladder symptoms had been present as long as she could remember.

CASE 8 had had severe temporal headaches since childhood, more likely to occur around the menstrual period, and for two years she had noticed stoppage of the right nostril. Nasal and x-ray examination revealed marked disease of the right frontal sinus.

CASE 2 gave a history of the passage of a ureter stone five years before her bladder trouble began; and CASE 7, who had bladder symptoms all her life, had passed a pea-sized stone from the bladder ten years before consultation.

In view of the causal relationship which I have previously pointed out (*J. A. M. A.*—Vol. lvi, pp. 937, also *International Clinics*, Vol. iv—Twenty-second series) between chronic urethritis and infections of the tonsils, adenoids, sinuses, and teeth, there may be some significance in the fact that every one of these cases had a granular urethritis. The tenderness and scar tissue contraction was so marked in most of the cases as to require thorough cocaineizing and careful manipulation in order to do satisfactory cystoscopy. Fenwick emphasizes this urethral hyperesthesia in most cases of non-malignant ulceration of the bladder and advises chloroform anesthesia for the cystoscopic examination. It is possible that the bladder ulceration and the inflammatory condition of the urethra may have a common cause, or it may be that the frequency of voiding and straining bring about an hypertrophy and hypersensitiveness of the sphincter region.

After these remarks bearing on the etiology, let us now return to a consideration of some of the clinical features associated with the ulcer itself. These ulcers have all been found in the vertex or summit or free portion of the bladder; this being one important distinction in comparing the simple solitary ulcer of Fenwick which is found on the base or fixed portion of the bladder.

In three of the cases the ulcer was well forward—just back of the symphysis; in four, it was in the summit, with a tendency in three of them to occupy the posterior pole region, while in one case there was an ulcer area near the posterior pole, and another on the left anterior wall immediately back of the symphysis.

With the knee-breast posture and the Kelly cystoscope we are at some disadvantage in locating ulcers on the anterior or pubic wall. On the other hand, a chief characteristic of these ulcers is the extremely slight mucous membrane change found in certain periods of the ulcer, and I am confident that we have an advantage

over the Nitze method in our clearer definition obtained by direct vision through an air medium. We have another great advantage in using the knee-breast posture and air distention in being able to study the ulcer under similar conditions at all times. Fenwick warns against positive conclusions from one study of an ulcer through the magnifying cystoscope, which gives such different pictures at varying distances, and the ulcer itself varying in size and appearance with different amounts of the distending fluid.

While cystoscopy usually reveals only one inflammatory spot, there may be two or three granulation areas near together or somewhat separated, and operation usually reveals a more extensive area of inflammation than was appreciated by cystoscopy.

The ulcer area may be easily overlooked and the attention may first be arrested by an area of dead white scar tissue. In the neighborhood of this scar-looking area, one sees one or more areas of hyperemia which, on being touched with a dry cotton pledget, or with the end of the speculum, bleed and first show their character as ulcers.

In other cases, or perhaps at subsequent examination on the same case, the ulcer may be well defined as a deeply red area with granulating base and with congested vessels surrounding the area. In none of these cases has an individual ulcer area been more than a half centimeter in diameter, although two or three such ulcers have at times been grouped in a larger inflammatory area.

At certain examinations the central inflammatory area is found surrounded with a fairly wide area of edema. This was seen on one examination in Case 5, and it was much more marked at operation. In Case 3, whom I had examined many times, edema was never seen at cystoscopy, but at operation an edematous oval area of about 5 x 3 centimeters surrounded the central ulcers, and this was removed with a margin of one centimeter of normal mucosa.

In Case 2, in addition to the small ulcer area in the left vertex, which has been studied for the past six years, there has occasionally been a slightly congested area near the posterior pole, perhaps four centimeters distant from the ulcer, and on one occasion there was edema about this posterior pole congestion.

I am not prepared to estimate the significance of this edema area, but until we know more about it, I shall try to excise it entirely at operation. I have never noticed it in any other class of bladder operations. I think some of the edema area was left in Case 5, and she is the only one of our five operated cases who is not well.

The cystoscopic picture reveals the granulation surface as on the same general level as the surrounding mucosa, in other words one would describe these ulcers at cystoscopy as being superficial. I have never seen a deposit of urinary

salts on one of this variety and the surface has never shown the ragged, irregular character suggesting a possible malignancy.

At operation, after opening the bladder, the slight granulation surface can be easily detected with the bared palpating finger, and one is surprised after the cystoscopic picture, suggesting a simple superficial process, to find at operation that some of these inflammatory processes extend through the bladder wall and involve the peritoneum.

The urine presents a macroscopically normal appearance and the few leucocytes and red blood corpuscles present may be entirely overlooked with the microscope, unless care is used to settle or centrifugalize the specimen. Indeed the patient may come complaining of about her usual symptoms, at a time when the urine is temporarily closed and the urine is absolutely negative on microscopic examination. At her next visit there may be the usual urine picture of a few leucocytes and a few red blood corpuscles, found only on careful examination, and cystoscopy reveals a granulating area, or a slightly hyperemic area which oozes blood on being touched.

The most characteristic sign or symptom of simple ulcer as described by Fenwick and others, is hemorrhage. Only one of my eight patients ever noticed anything abnormal in the urine. Case 7 had seen blood at times, but when she came for treatment, the urine as in all the other cases, looked macroscopically clear and contained only a few red cells and a few leucocytes.

Diagnosis. So far as I know there is no form of bladder inflammation or ulceration that has an absolutely characteristic clinical history or cystoscopic picture. The ulcer under discussion is no exception to the rule.

The patient's recital of the insidious onset without apparent antecedent cause, and the long duration in spite of various forms of treatment, make one think at once of tuberculous disease. This is excluded as soon as one finds macroscopically clear urine associated with such a long history and absence of any sign of disease of the kidney or ureter.

One sometimes gets a history of serious symptoms simulating cystitis from patients suffering with chronic urethritis. As stated above, these cases under discussion have all had signs of chronic urethritis, but the presence of microscopic pus or blood, or of both, in urine catheterized from women makes one certain that he is dealing with something more than a urethritis.

There is nothing absolutely characteristic in the cystoscopic picture. Perhaps the most characteristic thing is the insignificance of the lesion as compared with the long duration and intensity of the patient's suffering. As stated above, one's attention may first be arrested by the slight smooth white scars of former ulceration rather than by the slight hyperemia or inflammatory spots near these scars. In other cases

there is a small granulation area which is bleeding from the distention of the bladder, or bleeds easily on being touched. In other cases or at other examinations of the same case the inflammatory spot is occupied and surrounded by an area of edema. Anyone familiar with bladder work has seen slight lesions, similar in appearance to these under discussion, and has seen them clear up spontaneously or after a few instillations of some antiseptic drug. Such slight lesions are generally accompanied by infection and the healing depends upon ridding the bladder of infection. In gonorrheal infections this takes place spontaneously in a few weeks, or much sooner if the bladder is treated.

Our conclusion therefore is that a diagnosis of this peculiar form of bladder ulceration depends ultimately on its resistance to all ordinary forms of treatment.

The difficulty of diagnosis in this class of cases unless we are awake to their unusual features, is best illustrated by the fact that four of the eight cases had operations on other organs in the effort to relieve symptoms caused by the bladder ulcer.

Microscopically one finds in the resected portion of the bladder wall a typical picture of chronic, simple ulcer. The epithelial layer is absent at the site of the ulcer and the mucosa layer is occupied by typical, chronic granulation tissue. In some of the specimens this granulation tissue is fairly richly supplied with capillaries, but in most of them there is a preponderance of connective tissue and infiltration of small round cells and leucocytes.

The epithelium surface in the neighborhood of the ulcer shows multiple layers of the transitional type of cells, the external layers being of the squamous stratified type and in places appearing hornified. Next to the ulcer the epithelial layer may end abruptly with a precipitous edge or there may be seen extending beyond this abrupt edge an attempt at repair in the nature of a single layer of cuboidal cells growing toward the bare surface of the ulcer.

The mucosa layer in the neighborhood of the ulcer shows an increase in the number and size of the capillaries, varying in the different specimens. The capillaries are often stuffed with leucocytes, as are many of the lymph spaces. There are some enlarged lymph spaces crowded with lymphoid cells and leucocytes, and where these are seen lying beneath the normal epithelium near the ulcer, they at first suggest the picture of tubercle.

There is hyalin degeneration in some areas and in some of the sections the edema causes rarification.

Some of the specimens show considerable non-striated muscle in the mucosa coat in the neighborhood of the ulcers.

The muscle coat shows enlarged lymph spaces, and these as well as some of the blood vessels of the muscle coat, contain many leu-

cocytes. Immediately beneath the ulcer, the muscle in places shows invasion and breaking up by the inflammatory process. The peritoneum, which in Case 3 was thickened and torn at the time of operation, shows microscopically a fibrous thickening and in the tissues a few wandering leucocytes.

Treatment and Results. Of these eight cases, five have had excision of the diseased area, with probable perfect result in all but one, Case 5. Of the three unoperated cases, I have treated Case 2 six years, with apparent healing on two or three occasions. Case 8 has been treated about eight months with improvement in the symptoms, but with little change in the appearance of the bladder lesion. Case 4 is now being treated by Dr. John Caulk of St. Louis, her symptoms having improved, but the lesion persisting after four months of rather desultory treatment under my directions during the past summer.

My experience with this relatively small number of cases convinces me that excision is the treatment after one arrives at a diagnosis of this particular form of ulcer.

As stated under the discussion on diagnosis, I would not arrive at a final diagnosis calling for operation unless the patient has had systematic local treatment for the bladder symptoms and presents in addition the signs and symptoms above enumerated as more or less characteristic.

The excision is done through a suprapubic extraperitoneal incision. To facilitate the finding and handling of the bladder, it is left full of air if cystoscopy has just been done in the knee-breast posture, or it is distended with sterile fluid just before operation.

If the peritoneum is involved in the inflammatory process and is accidentally torn in peeling it from the muscle wall, it is sutured at once before opening the bladder.

The incision in the bladder wall is made with a view to open near but not into the inflammatory area.

In my first cases I was interested in palpating the ulcers with bare fingers, but this is not necessary and tends to change the microscopic picture. The inflammatory area is easily found by vision, and by doubling it back over the fingers on the outside or muscle wall, it can be excised with all layers of the bladder wall without touching the mucosa layer of the inflammatory area. As soon as removed, the specimen should be pinned to a stiff cardboard before passing it to the preservative fluid. Otherwise it quickly shrinks and mars the microscopic study.

The few blood vessels of consequence should be grasped with forceps, and after the excision they should be tied with fine (No. 1) twenty-day catgut. Otherwise they may retract into the muscle wall and temporarily cease to bleed, only to give trouble during the first few days of convalescence, as happened in Case 3.

The bladder edges are quickly brought together by a running, lock stitch suture of either ten- or twenty-day, No. 2 catgut, leaving a slight opening in the vertex through which the mushroom retention catheter is carried and sutured to the bladder wall with a No. 2, ten-day catgut. The abdominal wall is closed, except for a small opening to carry the rubber catheter and a cigarette drain, which is introduced down to the bladder wall.

The cigarette drain is removed at the end of forty-eight hours, and daily irrigations of the bladder with 1:10,000 solution of silver nitrate are carried on through the retention catheter, increasing the strength of the solution as the patient recovers. An ounce or two of the solution is introduced and immediately withdrawn through the catheter until several washings are made. This is best accomplished with the patient on her side.

The retention catheter is withdrawn on the tenth to the fourteenth day, after which the daily irrigations are given through the urethra until the bladder is free from infection.

EPIDIDYMYOTOMY FOR ACUTE EPIDIDYMITIS, AS AN OUT-PATIENT PROCEDURE.*

BY A. H. CROSBIE, M.D., BOSTON.

AND

A. RILEY, M.D., BOSTON.

INFLAMMATION of the epididymis occurs practically always secondary to inflammation of the deep urethra in the region of the ejaculatory ducts. This inflammation of the deep urethra is usually associated with involvement of the vesicles and prostate. The severity of the inflammation in the epididymis bears no relation to the severity of the inflammation in the deep urethra. In some of the most acute cases of epididymitis the posterior involvement seems to be almost nil.

The causative factors may be most any of the pus-producing bacteria or the tubercle bacillus. It very frequently happens that a patient who is on constant catheter drainage or who is catheterized frequently or has instrumentation, develops an acute epididymitis. These cases usually develop very rapidly and are accompanied by a considerable rise in temperature, pain, rapid pulse and malaise. The course of such an epididymitis is usually short, subsiding almost as rapidly as it appeared. In some of these, however, an abscess develops which may point outwardly and has to be opened or breaks spontaneously. This almost never occurs in those cases of gonorrheal origin. We have never known of anyone doing epididymotomy for

these non-gonorrheal cases, but we should think it would be advisable, provided the inflammation does not clear up quickly.

What we are dealing with in this paper is epididymitis caused by the gonococcus. Up to about a year ago at the Boston Dispensary we had been treating these cases conservatively by local applications, strapping, rest in bed with ice bags, etc. We found that such treatment had many drawbacks. In the very acute cases the pain was very severe for a week or more, the patients frequently looked septic and had malaise, even after a subsidence of the acute pain. Many of these patients continue to have dull pain and uneasiness at times for many months after. Then, too, after the acute symptoms have subsided and treatment of the urethritis, which had been suspended, is begun again, these cases which have been treated palliatively are very apt to recur.

Finding this palliative treatment far from satisfactory, a little over a year ago Dr. Augustus Riley and I began to perform epididymotomy on the very acute ones. The results have been so gratifying that now we advise operation, even in the milder ones. During the past year we have operated upon twenty-eight cases, two of which were double. In one the double infection came simultaneously and in the other first the left was involved, and in about ten days the other became infected. In this case when the second epididymis became infected the patient returned at once and asked to have the operation done.

Apparently the first man to do epididymotomy for gonorrheal epididymitis was a Frenchman named Pirogoff in 1852; later it was done by H. Smith in 1864. These men apparently only punctured the epididymis from the outside. The operation then was neglected until Francis P. Hagner revived it in 1906. Following his original report of six cases operated upon, a great many men have reported series of cases, and all who have done it are enthusiastic about the results.

The operative procedure that we use differs from that used by Dr. Hagner only in some small details. We suture the wound differently and we operate a great deal under local anesthesia. Dr. Hagner advised against local anesthesia.

At first we operated only under ether. This meant that the patient must either go to a hospital or have it done at home. We found that many cases were unable to enter a hospital and consequently had to get along without an operation. Finally we decided to operate under local anesthesia and let the patient go home after the operation. The results were so good that now we do even the most acute cases in this way.

We use from 20 to 30 c.c. of 1% novocaine, to which has been added from three to six drops of adrenal solution 1-1000. The method is much

* Read at a meeting of the New England Branch of the American Urological Association held in Boston on November 20, 1914.

the same as Braun, in his recent book on local anesthesia, advocates for any operation on the testes. The best syringe is a 10 c.c. glass syringe with a two-inch needle. The first step is to infiltrate the cord. This is done by grasping the cord, at the point where it emerges from the external ring, between the thumb and forefinger of the left hand. The needle is inserted into the cord and from five to ten c.c. of solution is

injected in all directions. It is well, also, before removing the needle, to point upward and inject a little solution into the inguinal canal, to be sure to get complete blocking of all the nerves in the cord. The needle is then pushed downward, through the same point of entry, along the cord, to the region of the globus major, and

Testicle dropped back and sutures in place ready to tie. The wick at the lower end of the incision.

a little more solution injected. The scrotum is then circuminjected on the side to be operated on, all the way to the perineum. This injection is made where the scrotal skin merges with the skin of the thigh. Even though the operation be unilateral Braun recommends anesthetizing the scrotal skin all the way around, the same as one would for a double operation. We have not found this necessary, as we get complete anesthesia by injecting the one side. Finally, a little novocain is injected along the line of incision. In order to get perfect anesthesia, it is well to wait ten or fifteen minutes. With the anesthesia thus obtained it is possible to handle the testicle and epididymis without the slightest discomfort. There is no sensation for two or three hours after, so that after operation a patient walks out really much more comfortably than he came in. Even after the anesthesia works off there is very little pain.

The incision is made laterally so that the tunica vaginalis is opened near the epididymis. A lateral incision of this sort is hardly visible after a few weeks. In the very acute cases there is always considerable hydrocele fluid, so that it is easy to cut through the tunica vaginalis, but in one of many days' duration it frequently happens that the hydrocele fluid has disappeared and the tunica vaginalis has become adherent to the tunica albuginea and one has to use care not to cut into the testicle. Twice we have nicked the testicle without apparent ill effect, but we prefer not to do it. On opening the hydrocele sac conditions vary. In some there is merely clear straw-colored fluid and no adhesions; in others the fluid is turbid, containing fibrin, as in a gonorrheal joint, and in some, particularly the long-standing ones, there are many adhesions, especially of the tunica vaginalis to the epididymis. With the blunt end of a knife or with a pair of scissors the adhesions are freed and the testicle and epididymis are delivered through the incision. The inflammation is usually most severe at the lower pole, the globus minor. This undoubtedly is due to the fact that

as the inflammation travels along the vas it hits this part first and lodges in the fine convoluted tubules. These undoubtedly become occluded and check the inflammation from proceeding. Occasionally the major is also involved and rarely the inflammation is worse in the major. Apparently it never reaches the testicle itself.

After delivering the testicle the epididymis is carefully examined. Where the inflammation is worst the epididymis is hard and indurated. Occasionally minute abscesses can be seen as yellowish white dots. It is very rare that there is a single abscess large enough to give definite fluctuation. Multiple punctures are made in the indurated area, whether or not there is visible pus, with a tenotome. The tenotome is plunged through the fibrous covering deep into the epididymis. It frequently happens that a drop of thick yellow pus wells up in the puncture. Smears from this pus nearly always show gonococci. Even though a drop of pus is found in one place it seems wise to puncture the whole indurated area. When a pus cavity is found, the hole is enlarged a little to allow free drainage. Occasionally in making these punctures a small artery is struck. This bleeding is easily stopped by a fine catgut stitch. After all the likely places have been punctured, it is well to wash off the testicle and epididymis with warm salt solution to remove the evacuated pus and blood clot. A drain either of gauze or rubber tissue is then placed lengthwise along the epididymis and brought out at the lower end of the incision. The testicle is then pushed back into the tunica. In closing, our technic differs from Dr. Hagner's. Hagner and others in the series they have reported close the tunica separately with continuous catgut suture. We close the wound loosely with silkworm gut sutures that pass through all layers. This allows any hydrocele fluid that forms to work out. In some cases, where the tunica has been tightly closed, we have seen hydrocele fluid persist for some time. A large dressing is applied and held in place with a T bandage. The patient is then allowed to go home and take a cathartic, and if possible to remain in bed for a couple of days. He later reports to the clinic for dressings. The wick is removed on the third or fourth day and the stitches in about a week. Although we advise rest in bed, in some cases the patient has not quit his work at all. The day following the operation a patient is apt to have fever, but usually with little pain. At the end of about thirty-six hours the temperature becomes normal and remains so.

Many of these cases when they come in look septic, and are in great pain. There frequently is a rise in temperature and pulse. Even the first day after operation the entire aspect of the patient has changed. The sallow septic look has gone. The relief from pain is almost miraculous. A patient requiring morphia in large

doses before operation generally sleeps without any drug, even the first night after operation.

Epididymotomy is a rational surgical procedure. Belfield likens epididymitis to the pus tubes in the female, and recommends surgical interference. It is perfectly easy to see why the pain is intense. There is pus under pressure and no adequate means of drainage. The vas offers no sort of an outlet. Without operation nature has to take care of the process. It means the absorbing of the pus into the system. This is a long process and must result in more damage to the tubules during the process of resolution than they could be damaged by the use of the knife. It seems logical that the method that will check the inflammation in the quickest possible way will give the best chance for a functional epididymis. It might seem as though puncturing an epididymis would block a great many tubules. It may, but it certainly does not destroy so many as would multiple undrained abscesses. In one recurring case, in our series, with a duration of seven months, practically the whole of the globus minor was replaced by an abscess cavity holding fully a dram of pus.

In the very early cases, that is, within forty-eight hours from onset, there usually is no definite pus. There is a great deal of edema and thickening of the epididymis. Punctures are followed by a serous ooze. In most of the later cases definite small abscesses are found. The relief of symptoms is just as marked in those having no pus as in those that do have it.

In only one case have we had a recurrence on the side operated upon and that was many months after, following an entirely fresh gonorrheal infection, exposure admitted by the patient. It is interesting to note that this man returned at once and requested operation.

After epididymotomy we have been able to start local treatment for the urethritis earlier than on patients not operated upon. We feel that this is one of the strong points in favor of the operation.

In all our cases the posterior involvement has yielded readily to treatment after operation. Frequently they clear up with remarkable rapidity. One man who at the time of operation has decidedly bloody urine and marked posterior symptoms, had both urines clear with shreds two days after operation. In one case that had very slight posterior involvement we became over-enthusiastic and passed sounds on the tenth day after operation. There was no recurrence on that side, but it did produce an acute epididymitis on the other side. He requested immediate operation.

We now start anterior irrigation about a week after operation and at the end of another week or more, depending upon the amount of posterior involvement, pass on to dilatation, bladder washes and massage.

The question of the effect of this operation

upon sterility, of course, is important. The operation shortens the duration of the inflammation without any doubt, and it seems reasonable to suppose that anything that does this is going to give the tubules a better chance to remain patent. It is hardly justifiable in a unilateral case to open the vas to see if there are motile spermatozoa, and any attempt to massage a single vesicle is futile, so that we must fall back on those with a double infection for our data. From the cases thus reported, the number of double infections is too small to draw any very definite conclusions, but those that we can draw are favorable. They certainly prove that the operation itself does not produce sterility. Cunningham in his fifty-seven cases had six double ones. Of these six, four had motile spermatozoa. Hagner in his series of sixty-three cases had three double cases, two cases of which had motile spermatozoa after operation. We have had only two double ones, and in only one of those have we had the opportunity to test for spermatozoa. This man was operated on for a very severe double infection twenty-four hours after it started. There was no pus but much serous ooze. Two months after operation the condom test showed many motile spermatozoa. This man married two months after operation against advice. At that time both his urines were clear with no shreds. His wife has been examined and there is no evidence that she has contracted the disease.

Without operation it is generally conceded that at least sixty-five per cent. of the double cases are sterile. Some writers put it much higher than that.

We feel that the following conclusions may be drawn:—

1. Epididymotomy invariably gives immediate and permanent relief of pain.
2. There are no recurrences after operation unless there is a fresh infection.
3. The course of the epididymitis without question is shortened, as is also the urethritis.
4. Patients are probably less likely to be sterile.
5. Treatment of the urethritis can be begun much earlier.
6. The operation can be safely and successfully done in an out-patient clinic under local anesthesia.

A STUDY OF LEPROSY: WITH ESPECIAL REFERENCE TO THE PULSE AND TEMPERATURE.

BY JAMES A. HONEIJ, M.D., BOSTON,

From Penikese Hospital and the Department of Bacteriology, Harvard University Medical School.

(Concluded from page 638.)

STUDY OF CONDITIONS THAT MAY POSSIBLY INFLUENCE TEMPERATURE AND PULSE.

Weather. A daily chart showing outside and inside temperature, direction and strength of wind, rain, fog, cloudiness, unsettled conditions and fair weather was kept. Comparisons were made in an effort to demonstrate any change in temperature and in pulse. From this study it was concluded that external temperature had not the slightest effect on the temperature and pulse of patients. On January 13 and 14 the external temperature was 2° above and 0 F. The lowest temperature was 96°, the highest 101°. The lowest pulse was 62 and the highest 114. On June 22, 23 and 29, the external temperature was 82°, 80°, 84° F. The lowest temperature was 97.4°, the highest 101.8°. The lowest pulse was 60 and the highest 100. These figures were taken at random, being highest and lowest on these days, excluding complications. The days have likewise not been especially chosen, and are not the extreme of either heat or cold.

It is unquestionably true that on foggy and rainy or excessively warm days there is a more or less general depression, considering that the patients are then forced to be indoors and are given time to reflect on their condition. It is more than likely that this factor plays as large a part as the weather conditions.

During the winter months the patients have complained of minor ailments and called for

medical attention more frequently than during the spring or summer months. Various charts were kept to determine from different points of view the condition and character of the temperature and pulse during the year divided into seasons, into months and into periods irrespective of seasons. The following table B. attempts to give graphically these results. From this it will be noticed that, with the exception perhaps of high temperature in August and high pulse in January and in contrast the low temperature in February and March and low pulse in July, August and September, no differences are noticeable for months, seasons or patients.

It is interesting to state here that chills which occur in the course of the disease and which have a marked effect on the character of the temperature and pulse curves, occurred most frequently in August, September, October and November, and that the feeling of cold was complained of most in December, January, March and April.

Observations on Effect of Exercise, etc. In leprosy physical exertion, of whatsoever nature, will give rise to an immediate and fairly prolonged reaction in temperature and pulse. This statement depends largely on the stage and condition of the disease and patient. The more advanced the stage and feeble the condition the greater the rise of temperature and pulse and the longer the duration of the reaction. The greater the activity the more variable are the temperature and pulse. Case 15 played croquet off and on for less than one hour and rested for half an hour before temperature and pulse were taken. Temperature was 102°, pulse 88. In this case the average temperature and pulse had been 99° to 100° and 70 to 80. In the other cases the same exercise caused various increases of temperature from 1.5° to 2.5° and pulse rate from 18 to 30. In most cases the reaction was still evident twelve hours after exercise and in an advanced case it was the cause of a severe

TABLE B.

A. T.	Jan.-June	Sept.-Oct., Nov.	Apr., Mar., Feb.	Dec., Oct.
Y. T.	*Jan.-Feb.	June	Jan., October	June, Aug.

Month of highest temperature is given first.

In case of slight differences more than two months are given.

Two months connected by hyphen show increase in latter part of one month and first part of next month.

* During these months complications or "toxic-febrile" attacks occurred.

indisposition of several days duration. In washing both floors and clothes, where a certain amount of friction is used, patients have shown marked local and systemic reactions. In one case the average increase of temperature is 1+ degrees and pulse 16+ beats, with constant skin reaction in the nature of bullae or inflamed abrasions. The more constant and graduated the exercise the less the reaction.

Results from Resting. The year of observation was divided into alternate periods of six weeks of rest for one-half hour before temperature and six weeks when patients came directly from the various occupations to the dispensary. This again was divided into a week period when some of the patients stayed in bed for temperature and pulse readings, and readings were also made when patients were indisposed for longer or shorter periods. Two cases are given here as an illustration, as typical of all cases (Cases 5 and 8.) Study of Chart 5 shows during the periods of rest a lower and more regular temperature. "Morning pulse" was present 65% of the time. During the exercise periods pulse exacerbations were more frequent and the rate more variable. In general temperature and pulse and respiration are much higher at both morning and evening readings. "Morning pulse" was present 42% of the time. Case 8 is an early case with infrequent and slight lesions and of good physical condition. The results of partial rest upon the temperature and pulse curves are similar to those just noted. Chart 19 illustrates the effect of complete rest upon curves in case 8.

Under Abnormal Conditions. Elsewhere it has been stated that temperature and pulse reactions occur from the slightest cause. This reaction which is most markedly shown by the sudden rise and pulse rate is dependent largely upon the general health of the patient and the character of the cause. In secondary infections, diarrhea, influenza, pleuritis and common cold,

there occurs an immediate departure from the typical temperature and pulse curves of leprosy, yet different from the reaction seen in a "toxic-febrile" attack. The severe prostration, general malaise, exhaustion and marked elevation of temperature and pulse are out of all proportion to the physical findings and the speedy recovery which follows. Chart 5, studied in comparison with chart 1, and then contrasted with chart 11 will better describe these changes. A daily study of the charts will usually immediately indicate the occurrence of some impending disturbance and is almost always corroborated by the patient in a day or two. In this manner many "toxic-febrile" attacks have been prognosticated and pus, usually in the extremities, has been demonstrated early in the disorder. As a result these attacks are shortened, if not aborted. A comparison of the charts showing "toxic-febrile," attacks and reactions due to exercise or excitement will demonstrate the difference in such curves. See charts 2 and 14.

Explanation: * Incomplete months. † Question of pulmonary tuberculosis. ‡ Complications. † Only comfortable months.

Two other patients with uncompleted charts are not included here.

H. C. Case discharged as arrested.

W. Q. Patient has shown marked improvement.

L. D., S. G., and Y. T., are cases showing severe complications during year.

Table D is an attempt to show the reduced percentage of the occurrence of the high "morning pulse" rate, due to complications. The months of the year showing the fewest complications, give the greatest percentage of "morning pulse," *i. e.* March, April, May and June of 1914.

Effect of Medical and Surgical Treatment. All drugs, especially those used externally in leprosy, will have some effect on the patient's temperature and pulse. The general physical condition of the patient and the presence of ulcers or other lesions determine the initial course of the disease and when any specific treatment is undertaken, the result is looked for on the chart to determine the effect of such treatment in conjunction with objective and subjective symptoms. The daily condition of the patient is more largely dependent on the presence of pus or secondary infections, as seen in "toxic-febrile" attacks, and any drug which is used, such as iodoform ointment, acting directly on the ulcer and indirectly on the system will, if effective, produce a result that is observed by fall of temperature and pulse rate and particularly, in the character of the curves. This study has been without definite results and no conclusions can be reached, as many other factors are constantly entering into the study of the immediate reactions by the internal administration of drugs, which under the present system cannot be controlled. Only by the study of the cases during long periods can the efficacy of any treatment be obtained.

General Hygiene. Under this heading there has been included bathing, clean clothes, fresh air, food and as much as possible, the effect of clean surroundings. The result can only be summed up in a general statement by saying that cleanliness and fresh air are most important adjuncts in the treatment of leprosy and sufficient emphasis can hardly be laid on this question. The reaction observed after baths is not consistent, consequently no conclusions are

made. Table E is presented here showing the loss and gain in weight for the year under observation. Explanation of the figures is seen at the bottom of the table.

Effect of Mental States. In all cases there are periods of severe depression. Lesions associated with pain, disability or loss of appetite, produce the greatest proportion of these attacks. The temperature and pulse are lower during such times, with no other marked characteristic. Excitement, especially due to anger, produces a marked increase of pulse rate. This increase is often 40 beats and more above the individual's average rate. The reaction continues for a time not less than 48 hours and often for longer periods (see chart 2) and not infrequently ends in indisposition of varying severity, accompanied by rise of temperature, malaise and digestive disturbances. Pain which is sufficiently severe to need attention, will, without exception, give rise to first, an increased pulse rate and later to a rise in temperature, the height of each being entirely dependent upon the cause of the pain. Other conditions have already been mentioned which have a depressing effect on the patient's mind.

The Effect of Age, Sex and Racial Characteristics. With the exception of one case it has been difficult to arrive at any decision regarding the effect of age on the temperature and pulse curves during the course of the disease, when complications were not present. The exception is in a patient seventy years of age. Both the temperature and pulse rate are in general lower than the temperature and pulse rate of those patients whose stage and condition are similar to his. The irregularity is more marked and reactions from slight causes more numerous, severe and prolonged. In certain periods the temperature and pulse are below the normal. In this case it has not been possible to determine how great an influence his cardiac lesions affected the readings. With the women patients it has been observed that, excluding certain affecting

* November.

One patient discharged, gained in weight.

Patients in most advanced stages, show greatest loss of weight.

agents and temperament, the rate is higher, reactions are more marked and disturbances more frequent. There seems to be a nervous factor which may account in part for these reactions. In the case of racial influence, it can be said that suggestion and mental treatment are of value in the Jewish patients only. These patients need constant encouragement. They react to outside influences in a more marked manner than the rest. Their habits of living make treatment more difficult. In no specific way can it be said that these reactions predominate over the reactions of leprosy. It cannot be determined without longer study of more cases.

DISCUSSION AND CONCLUSION.

In normal individuals the temperature and heart rate fall and rise together in parallel curves.

The heart's action is modified by an increase in temperature and reacts differently according to the toxins produced by the agent causing the fever. Variations occur, especially when peripheral vessels and nerves are involved. This is seen in minor febrile troubles when a slight rise of temperature is accompanied by a fall in pulse rate.
